Orphan Temporary Tables

If MySQL exits in the middle of an `ALTER TABLE` operation, you may be left with an orphan temporary table that takes up space on your system. This section describes how to identify and remove orphan temporary tables.

Orphan temporary table names begin with an `#sql-` prefix (e.g., `#sql-540_3`). The accompanying `.frm` file has the same base name as the orphan temporary table.

> **Note**
>
> If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan temporary table (it must have the same columns and indexes) and must be placed in the database directory of the orphan temporary table.

To identify orphan temporary tables on your system, you can view Table Monitor output. Look for table names that begin with `#sql`. If the original table resides in a file-per-table tablespace, the tablespace file (the `#sql-*.ibd` file) for the orphan temporary table should be visible in the database directory.

To remove an orphan temporary table, drop the table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-540_3`;
```

The `#mysql50#` prefix tells MySQL to ignore `file name safe encoding` introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as "#".

Tablespace Does Not Exist

With `innodb_file_per_table` enabled, the following message might occur if the `.frm` or `.ibd` files (or both) are missing:

```
InnoDB: in InnoDB data dictionary has tablespace id N,
InnoDB: but tablespace with that id or name does not exist. Have
InnoDB: you deleted or moved .ibd files?
InnoDB: This may also be a table created with CREATE TEMPORARY TABLE
InnoDB: whose .ibd and .frm files MySQL automatically removed, but the
InnoDB: table still exists in the InnoDB internal data dictionary.
```

If this occurs, try the following procedure to resolve the problem:

1. Create a matching `.frm` file in some other database directory and copy it to the database directory where the orphan table is located.

2. Issue `DROP TABLE` for the original table. That should successfully drop the table and `InnoDB` should print a warning to the error log that the `.ibd` file was missing.

14.6.12.4 InnoDB Error Handling

The following items describe how `InnoDB` performs error handling. `InnoDB` sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in the tablespace, a MySQL `Table is full` error occurs and `InnoDB` rolls back the SQL statement.

- A transaction deadlock causes `InnoDB` to roll back the entire transaction. Retry the whole transaction when this happens.

  A lock wait timeout causes `InnoDB` to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option, available as of MySQL 5.1.15.) Retry the statement if using the current behavior, or the entire transaction if using `--innodb_rollback_on_timeout`.

  Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

  When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.

- A `row too long error` rolls back the SQL statement.

- Other errors are mostly detected by the MySQL layer of code (above the `InnoDB` storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL statement, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

14.7 The IBMDB2I Storage Engine

The `IBMDB2I` storage engine is designed as a fully featured transaction-capable storage engine that enables MySQL to store its data in DB2 tables running on IBM i. With the `IBMDB2I` storage engine, data can be shared between MySQL applications and applications coded for native DB2 for i interfaces.

`IBMDB2I` provides ACID-compliant transactions, support for foreign key constraints, full crash recovery, radix-tree-based indexes, and the unique ability to enable DB2 for i applications to see and update table data in real time.

More information about the storage engine and its interaction with DB2 for i can be found in IBM's *Using DB2 for i as a Storage Engine for MySQL* Redbook publication, at IBM DB2 for i a Storage Engine for MySQL Redbook.

> **Note**
>
> The `IBMDB2I` storage engine was introduced in MySQL 5.1.33 and considered GA in MySQL 5.1.35. It was removed in MySQL 5.1.54.

14.7.1 Installation

Because it relies on features specific to the IBM i operating system running on IBM Power systems, the `IBMDB2I` storage engine is only available on builds of MySQL specifically created for the IBM i operating system.

IBM i 5.4 or later is required to run `IBMDB2I`. Some features may require IBM i 6.1 or later versions. As well, a set of program temporary fixes (PTFs) must be installed. Information about the specific PTF numbers can be obtained from http://www-912.ibm.com/n_dir/nas4apar.nsf/c79815e083182fec862564c00079d117/67d12878076e4827862574e2003c6d4a?OpenDocument.

The engine is built as a dynamic plugin and so must be installed by using the following command:

```
mysql> INSTALL PLUGIN ibmdb2i SONAME ha_ibmdb2i.so;
```

14.7.2 Configuration Options

Table 14.6 `IBMDB2I` Storage Engine Features

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
ibmdb2i_assume_exclusive_use	Yes	Yes	Yes		Global	Yes
ibmdb2i_async_enabled	Yes	Yes	Yes		Both	Yes
ibmdb2i_compat_opt_allow_zero_date_vals	Yes	Yes	Yes		Both	Yes
ibmdb2i_compat_opt_blob_cols	Yes	Yes	Yes		Both	Yes
ibmdb2i_compat_opt_time_as_duration	Yes	Yes	Yes		Both	Yes
ibmdb2i_compat_opt_year_as_int	Yes	Yes	Yes		Both	Yes
ibmdb2i_create_index_option	Yes	Yes	Yes		Both	Yes
ibmdb2i_lob_alloc_size	Yes	Yes	Yes		Both	Yes
ibmdb2i_max_read_buffer_size	Yes	Yes	Yes		Both	Yes
ibmdb2i_max_write_buffer_size	Yes	Yes	Yes		Both	Yes
ibmdb2i_propogate_default_col_vals	Yes	Yes	Yes		Both	Yes
ibmdb2i_rdb_name	Yes	Yes	Yes		Global	No
ibmdb2i_system_trace_level	Yes	Yes	Yes		Global	Yes
ibmdb2i_transaction_unsafe	Yes	Yes	Yes		Both	Yes

- `ibmdb2i_assume_exclusive_use`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_assume_exclusive_use`	
System Variable	**Name**	`ibmdb2i_assume_exclusive_use`
	Variable Scope	Global
	Dynamic Variable	Yes

Permitted Values (IBM System i)	Type	`boolean`
	Default	`off`

Specifies whether an external interface (such as DB2 for i) may be altering the data accessible by the `IBMDB2I` engine. This is an advisory value that may improve performance when correctly set to ON. When the value is ON, `IBMDB2I` may perform some internal caching of table statistics. When the value is set to OFF, `IBMDB2I` must assume that the table rows could be inserted and deleted without its direct knowledge and must call DB2 to obtain accurate statistics before each operation.

Default Value: OFF

- `ibmdb2i_async_enabled`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_async_enabled`	
System Variable	Name	`ibmdb2i_async_enabled`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	Type	`boolean`
	Default	`on`

Specifies whether buffering between `IBMDB2I` and the QSQSRVR jobs responsible for fetching row data should be done in an asynchronous manner. Asynchronous reads are enabled by default and provide optimal performance.Under normal circumstances, this value will never need to be modified.

Default Value: ON

- `ibmdb2i_create_index_option`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_create_index_option`	
System Variable	Name	`ibmdb2i_create_index_option`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	Type	`numeric`
	Default	`0`

Controls whether additional indexes are created for use by traditional DB2 for i interfaces. When the value is 0, no additional indexes will be created. When the value is 1 and the index created on behalf of MySQL is ASCII-based, an additional index is created based on EBCDIC hexadecimal sorting. The additional index may be useful for traditional DB2 for i interfaces which expect indexes to use EBCDIC-based sort sequences.

Default Value: 0

- `ibmdb2i_compat_opt_time_as_duration`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_compat_opt_time_as_duration`	
System Variable	**Name**	`ibmdb2i_compat_opt_time_as_duration`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	**Type**	`boolean`
	Default	`off`

Controls how MySQL TIME columns are mapped to DB2 data types when creating or altering an `IBMDB2I` table. When the value is `ON`, the column is mapped to an `INTEGER` type in DB2 and supports the full range of values defined by MySQL for `TIME` types. When the value is `OFF`, the column is mapped to a DB2 `TIME` type and supports values in the range of '00:00:00' to '23:59:59'. This option is provided to provide enhanced interoperability with DB2 for i interfaces.

Default Value: OFF

- `ibmdb2i_system_trace_level`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_system_trace_level`	
System Variable	**Name**	`ibmdb2i_system_trace_level`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (IBM System i)	**Type**	`boolean`
	Default	0

Specifies what kind of debugging information is to be gathered for `QSQSRVR` jobs servicing MySQL connections. Multiple sources of information may be specified by summing the respective values. Changes to this option only affect new connections. Valid values include

- `0`: No information (Default)

- `2`: `STRDBMON`

- `4`: `STRDBG`

- `8`: `DSPJOBLOG`

- `16`: `STRTRC`

- `32`: `PRTSQLINF`

The most useful sources of information are `DSPJOBLOG`, which will capture the job log for each `QSQSRVR` job in a spoolfile, and `STRDBG`, which will increase the diagnostic information in each job log.

Default Value: 0

- `ibmdb2i_compat_opt_allow_zero_date_vals`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_compat_opt_allow_zero_date_vals`	
System Variable	**Name**	`ibmdb2i_compat_opt_allow_zero_date_vals`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	**Type**	`boolean`
	Default	`0`

Specifies whether the storage engine should permit the `0000-00-00` date in `DATETIME`, `TIMESTAMP` and `DATE` columns. When the option is 0, attempts to insert a row containing this zero date into an `IBMDB2I` table will fail. As well, a warning will be generated when creating a column with this zero value as the default value. When this option is 1, the zero value will be substituted with `0001-01-01` when stored in DB2, and a `0001-01-01` value will be translated to `0000-00-00` when read from DB2. Similarly, when a column with a default zero value is created, the DB2 default value will be '0001-01-01'. Users must be aware that, when this option is 1, all values of `0001-01-01` in DB2 will be interpreted as `0000-00-00`. This option is primarily added for compatibility with applications which rely on the zero date.

Default Value: 0

- `ibmdb2i_propagate_default_col_vals`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_propogate_default_col_vals`	
System Variable	**Name**	`ibmdb2i_propogate_default_col_vals`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	**Type**	`boolean`
	Default	`on`

Specifies whether `DEFAULT` value associated with each column should be propagated to the DB2 definition of the table when a table is created or altered. The default value is ON. This ensures that rows inserted from a standard DB2 interface will use the same default values as when inserted from MySQL.

Default Value: ON

- `ibmdb2i_compat_opt_year_as_int`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_compat_opt_year_as_int`	
System Variable	**Name**	`ibmdb2i_compat_opt_year_as_int`
	Variable Scope	Global, Session

	Dynamic Variable	Yes
Permitted Values (IBM System i)	**Type**	`boolean`
	Default	`0`

Controls how YEAR columns are stored in DB2. The default is 0 and causes `YEAR` columns to be created as `CHAR(4) CCSID 1208` columns in DB2. Setting this option to 1 causes the YEAR columns to be created as `SMALLINT` columns. This provides a slight performance increase and enables indexes that combine a `YEAR` column with a character column.

Default Value: 0

- `ibmdb2i_lob_alloc_size`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_lob_alloc_size`	
System Variable	**Name**	`ibmdb2i_lob_alloc_size`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	**Type**	`numeric`
	Default	`2MB`

Controls how much space is allocated by default for reading data from a `BLOB` or `TEXT` field. If an application consistently uses `BLOB` or `TEXT` fields that contain more than 2 MB of data, read performance may be improved if this value is increased. Conversely, an application which uses smaller `BLOB` or `TEXT` fields may find that the MySQL memory footprint is reduced if a smaller value is specified for this option.

Default Value: 2 MB

- `ibmdb2i_compat_opt_blob_cols`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_compat_opt_blob_cols`	
System Variable	**Name**	`ibmdb2i_compat_opt_blob_cols`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	**Type**	`numeric`
	Default	`0`

Specifies how MySQL `TEXT` and `BLOB` columns larger than 255 characters are mapped when creating `IBMDB2I` tables. When the value is 0, `TEXT` columns are mapped to `CLOB` or `DBCLOB` columns for DB2 for i. This enables the column to contain the maximum size documented for `TEXT` columns (64K characters), but the column can not be included in an index. When the value is 1, `TEXT` columns are mapped to `LONG VARCHAR`/`VARGRAPHIC` columns, and `BLOB` columns are mapped to `LONG`

`VARBINARY`. This permits indexes to be created over the column, but it reduces the amount of storage available to the column below the documented maximum for `TEXT` columns. This option was provided to enable applications which relied on the ability to create prefix indexes over `TEXT` columns.

Default Value: 0

- `ibmdb2i_max_read_buffer_size`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_max_read_buffer_size`	
System Variable	**Name**	`ibmdb2i_max_read_buffer_size`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	**Type**	`numeric`
	Default	`1MB`

Controls the maximum amount of memory allocated for buffering row data when doing reads from an `IBMDB2I` table. This buffering is done independently of any row buffering done within MySQL proper. Setting this value too low may reduce read performance, while setting it too high may increase memory usage and may also reduce read performance.

Default Value: 1 MB

- `ibmdb2i_max_write_buffer_size`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_max_write_buffer_size`	
System Variable	**Name**	`ibmdb2i_max_write_buffer_size`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	**Type**	`numeric`
	Default	`8MB`

Controls the maximum amount of memory allocated for buffering row data when inserting multiple rows into an `IBMDB2I` table. This buffering is done independently of any row buffering done within MySQL proper. Setting this value too low may reduce write performance, while setting it too high may increase memory usage.

Default Value: 8 MB

- `ibmdb2i_rdb_name`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_rdb_name`	
System Variable	**Name**	`ibmdb2i_rdb_name`

	Variable Scope	Global
	Dynamic Variable	No
Permitted Values (IBM System i)	Type	`string`
	Default	

The name of a local DB2 for i relational database that will act as a container for all `IBMDB2I` tables. This enables an independent auxiliary storage pool (IASP) to be selected for usage. If no value is specified, the system database (*SYSBAS) is used.

Default Value: <blank>

- `ibmdb2i_transaction_unsafe`

Introduced	5.1.33	
Command-Line Format	`ibmdb2i_transaction_unsafe`	
System Variable	Name	`ibmdb2i_transaction_unsafe`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (IBM System i)	Type	`boolean`
	Default	`off`

Controls whether `IBMDB2I` honors the transactional commands and isolation levels specified for MySQL. If the value is OFF, transactions are fully supported. If the value is ON, transactional behavior is not implemented. This may provide a moderate performance increase for applications that do not rely on transactional guarantees.

Default Value: OFF

The values specified for `ibmdb2i_create_index_option`, `ibmdb2i_create_time_columns_as_tod`, `ibmdb2i_map_blob_to_varchar`, `ibmdb2i_compat_opt_allow_zero_date_vals`, `ibmdb2i_propagate_default_col_vals`, and `ibmdb2i_propagate_default_col_val` will be applied whenever an `IBMDB2I` table is created. Tables are implicitly destroyed and re-created when an `offline ALTER TABLE` is performed on an `IBMDB2I` table. Therefore it is highly recommended that the values of these variables be consistent across the lifetime of a table to prevent an `ALTER TABLE` from running under a different set of options than were used to originally create the table. If this recommendation is not followed, the `ALTER TABLE` may fail upon encountering incompatible data when re-creating the table.

14.7.3 Creating schemas and tables

`IBMDB2I` tables are created by specifying the `ENGINE=IBMDB2I` option on a `CREATE TABLE` or `ALTER TABLE` statement. These tables are stored as DB2 for i objects in the QSYS.LIB file system. Therefore, in contrast to the behavior of other storage engines, `IBMDB2I` table and index data does not reside beneath the datadir directory with other MySQL table data.

When the first `IBMDB2I` table is created in a MySQL schema, the corresponding DB2 schema will be created (if it does not already exist).

Note that if the user profile running MySQL has sufficient authority dropping a MySQL schema will drop a DB2 schema of the same name even if the schema never contained any `IBMDB2I` tables and contains objects not related to MySQL. Therefore, it is recommended that extreme caution be used when dropping MySQL schemas when the `IBMDB2I` plugin is installed.

14.7.3.1 Identifier names

DB2 for i file objects have both a short (10-character) system name and an SQL name. The DB2 for i SQL name is always the same as the MySQL name. However, because MySQL's sensitivity to the lettercase of schema and table names depends on the file system containing the datadir, mapping the MySQL name to the system name of the corresponding DB2 for i object must account for several factors, described below.

When MySQL is operating in a case-sensitive mode (that is, datadir is in a case-sensitive file-system like (/QOpenSys), the case of the system name of the `IBMDB2I` object reflects the case of the name specified to MySQL. If the object has all uppercase characters and is equal to or less than 10 characters in length, the system name will be undelimited and in uppercase.If the object name has mixed or lower-case letters, the IBM i system name will contain up to 8 characters of the name in the specified case and will be delimited by surrounding quotation marks. If the MySQL name has more characters than can fit in the delimited system name, the system name will be generated as a mangled name delimited by surrounding quotation marks.

Examples of this naming behavior are given below:

Table 14.7 Naming Behavior in DB2 Storage Engine

MySQL name	DB2 for i SQL name	IBM i System name
mytable	mytable	"mytable"
mylongertable	mylongertable	"mylo0001"
UPPERTABLE	UPPERTABLE	UPPERTABLE
UPPERLONGTABLE	UPPERLONGTABLE	UPPER00001
MixedTab	MixedTab	"MixedTab"
MixedlongerTab	MixedlongerTab	"Mixe0001"

If MySQL is operating in a case-insensitive mode, the IBM i system name will contain up to 8 characters of the name in lower case and will be delimited by surrounding quotation marks. If the MySQL name has more characters than can fit in the delimited system name, the system name will be generated as a mangled name delimited by surrounding quotation marks.

Note that IBM i system names are not changed when a RENAME TABLE command is executed. Only the DB2 for i SQL name changes.

14.7.3.2 Index names

Unlike MySQL, DB2 for i requires that index names be unique to an entire schema. To support MySQL indexes, `IBMDB2I` creates the DB2 for i indexes with modified file names. The generated name is a concatenation of the index name, three underscores (_), and the table name. For example, `CREATE INDEX idx1 ON tab1 (a, b)` would create a DB2 index named `idx___tab1`. If the ibmdb2i_create_index_option value is set to 1, an additional index may be created which is named with an additional `H_` marker between the index and table names (for example, idx___H_tab1). These generated names are then mangled to create the an IBM i system name, as described above.

If a table is renamed, the indexes will also be renamed.

This index name generation scheme also has implications for the length of index and table names; to permit the generated name and allow for delimiting quotation marks, the combined length of the index and table names must be less than or equal to 121 characters.

Data type mapping

When creating a table, `IBMDB2I` may map the MySQL types specified on a `CREATE TABLE` statement into a corresponding or compatible DB2 for i type. Examples include the `BIT` type, which is stored as a `BINARY` field, or the `MEDIUMINT` type, which is stored as an `INTEGER` field. For most data types, this mapping is transparent. Data types which have restrictions unique to `IBMDB2I` are documented in Section 14.7.7, "Notes and Limitations".

14.7.4 Database/metadata management

When an `IBMDB2I` table is created, a File Level ID (FID) file is created in the database directory. This file has an extension .FID and contains the last known FID of the associated DB2 for i physical file. The `IBMDB2I` engine uses this FID value to determine whether incompatible changes have been made to the table by an external (non-MySQL) interface. If the physical file is altered, DB2 for i automatically generates a new FID. The next time `IBMDB2I` attempts to access the file, it will detect that the new FID does not match the known FID, and it will prevent MySQL from using the table.

In some cases, the changes to the physical file that cause the FID to be updated may not adversely affect access through MySQL and `IBMDB2I`. In this case, a user may wish to override the FID check that `IBMDB2I` performs. A user with appropriate permissions may do so simply by deleting the `.FID` file associated with the table and performing a `FLUSH TABLE` statement against the table. `IBMDB2I` will then regenerate the file with the new FID the next time the table is accessed from MySQL.

If triggers or constraints are applied to the table from a native DB2 interface, they will be respected when accessing the table from MySQL, but MySQL will have no knowledge of the triggers or constraints. Likewise, views and indexes can be created over the tables from a DB2 interface, but the indexes will not be accessible from MySQL.

14.7.5 Transaction behavior

The `IBMDB2I` storage engine supports row-level transaction management. All MySQL isolation levels are supported by the engine, and where highest performance is required, transaction support can be disabled globally or per session by modifying the ibmdb2i_transaction_unsafe configuration option.

`IBMDB2I` uses the underlying DB2 for i transaction support to implement MySQL isolation levels. DB2 for i uses table and row locks to implement the various isolation levels, as described below:

Table 14.8 IBMDB2I Isolation Levels

Isolation level	Read-only (SELECT)		Read-write (UPDATE, DELETE)	
	Lock enforcement	Visibility of uncommitted work on behalf of other connections	Lock enforcement	Visibility of uncommitted work on behalf of other connections
SERIALIZABLE	Table is locked until end of transaction.Other connections may read rows while locked.	N/A	Table is locked until end of transaction.Other connections may	N/A

Isolation level	Read-only (SELECT)		Read-write (UPDATE, DELETE)	
	Lock enforcement	Visibility of uncommitted work on behalf of other connections	Lock enforcement	Visibility of uncommitted work on behalf of other connections
			read rows while locked.	
REPEATABLE READ	Rows that have been read are locked until end of transaction.Other connections may read and insert rows while locked.	Rows cannot be read until work is committed.	Rows that have been read are locked until end of transaction.Other connections may read and insert rows while locked.	Rows cannot be read until work is committed.
READ COMMITTED	Row is locked while cursor is positioned on that row.Other connections may read and insert rows while locked.	Rows cannot be read until work is committed.	Row is locked while cursor is positioned on that row.Other connections may read and insert rows while locked.	Rows cannot be read until work is committed.
READ UNCOMMITTED	Row is locked while cursor is positioned on that row.Other connections may read and insert rows while locked.	Rows can be read before work is committed.	Row is locked while cursor is positioned on that row.Other connections may read and insert rows while locked.	Rows can be read before work is committed.
transaction_unsafe	No locks	Full access	Table is locked until end of transaction.Other connections may read rows while locked.	Unrestricted access

Attempts to access locked rows time out according to the timeout value associated with the underlying DB2 physical file. This timeout wait is 30 seconds by default. Refer to http://publib.boulder.ibm.com/infocenter/ iseries/v5r4/index.jsp?topic=/dbp/rbafoconcrec.htm for more information.

Because `IBMDB2I` does not multi-version rows under commitment control, row lock contention may occur under certain scenarios. In particular, when multiple connections attempt to read overlapping ranges of rows while performing a statement that does updates, the connections may contend for the same row locks. This may lead to delays until the row lock timeout expires. Creating appropriate indexes and increasing query selectivity to reduce range overlap may help to alleviate this contention.

14.7.6 Principles and Terminology

`AUTO_INCREMENT`

The MySQL auto_increment column attribute can be used to generate a unique identity for new rows.The `IBMDB2I` storage engine maps the MySQL auto_increment attribute to the DB2 for i identity attribute

For most MySQL storage engines, the auto_increment value is determined by adding one to the maximum value stored in the table for the column.For the `IBMDB2I` storage engine, DB2 for i generates the identity

value by adding one to the last generated value. Following are some example MySQL statements to illustrate the point.

```
create table t1 (a int auto increment, primary key(a)) engine = ibmdb2i;
insert into t1 values(3);
insert into t1 values(null),(null);
```

For the first INSERT statement, an explicit value of 3 is specified for the auto_increment column, so the value 3 is stored in the inserted row.For the second INSERT statement null is specified, so generated values 1 and 2 will be stored in the rows.

Duplicate key failures can occur in DB2 for i if a MySQL application mixes explicit auto_increment values with generated values within a table. For the example above, if one more record is inserted into the table for which an auto_increment value is generated, a duplicate key error will occur because the value 3 (that is, the last generated value plus one) already exists in the table.To effect the MySQL behavior for auto_increment columns, the `IBMDB2I` storage engine will detect a duplicate key error, alter the restart value for the DB2 identity column to the maximum value plus one, and retry the failed insert, but only if the following conditions are true:

- The duplicate key error occurred on an index for which the auto_increment column is a key field

- An exclusive (LENR) lock can be acquired on the table

- The error occurred on the first or only row of the `INSERT` statement.

The `IBMDB2I` storage engine does not support the following usage of auto_increment columns:

1. Any MySQL global or session variable that affects the start, increment, or offset for generated auto_increment values.

2. Any MySQL feature that returns the *next value to be used* for an auto_increment column.

3. An auto_increment column on a MySQL partitioned table.

14.7.7 Notes and Limitations

- When using multiples instances of MySQL on a single i5 host you should be aware that the two independent instances will access the same database within the DB2 environment. This can lead to namespace collisions and issues. To get round this limitation, you should configure different IBM i independent auxiliary storage pools (ISAPs) for each MySQL server, and then use the `ibmdb2i_rdb_name` option to MySQL to configure which IASP should be used for each MySQL instance.

- Indexes over `VARBINARY` columns may not provide accurate estimates the optimizer. Queries over such indexes may produce error 2027 in the error log but will succeed. This affects only the performance of these queries, not the correctness of the results.

- Setting `ibmdb2i_system_trace_level = 16 (STRTRC)` may cause unpredictable failures including error 2088 on some operations. This is unlikely to affect any users, as this value is recommended only for serviceability purposes.

- `IBMDB2I` honors the `CASCADE`/`RESTRICT` option on the `DROP TABLE` statement.

- The use of `FLUSH TABLES WITH READ LOCK` is discouraged when using `IBMDB2I` tables. Due to differences in internal locking implementations, `FLUSH TABLES WITH READ LOCK` may produce deadlocks on `IBMDB2I` tables.

- Row-based replication is supported by `IBMDB2I`. Statement-based replication is not supported.

- Schema name lengths are limited to 10 characters in IBM i 5.4 and 30 characters in IBM i 6.1. If the schema name is mixed- or lower-case, two characters must be subtracted from the limit to account for surrounding quotation marks.

- The RENAME TABLE command cannot be used to move `IBMDB2I` tables from one database to another.

- The maximum length of the internal row format for `IBMDB2I` is 32767 bytes. Because the internal row format may differ from the MySQL row format due to data mapping differences (see Creating schemas and tables section), anticipating this limit may be difficult.

- The combined length of the index and table names must be less than or equal to 121 characters.

- Indexes over TEXT or BLOB columns with a maximum length greater than 255 characters are not supported. The ibmdb2i_map_blob_to_varchar option can be used to work around this limitation for TEXT fields up to 64K characters.

- Specific restrictions apply to certain data types as described in the following chart:

Table 14.9 Data Type Restrictions in IBMDB2I

MySQL data type	Restriction
`LONGBLOB` or `LONGTEXT`	The maximum length of a DB2 BLOB data type is 2GB.
`DATE`	`IBMDB2I` does not support the special date value of '0000-00-00'. The restrictions on `DATE` and `DATETIME` columns can be removed by setting the value of `ibmdb2i_compat_opt_allow_zero_date_vals` to 1.
`DATETIME`	`IBMDB2I` does not support the special datetime value of '0000-00-00 00:00:00'. The restrictions on `DATE` and `DATETIME` columns can be removed by setting the value of `ibmdb2i_compat_opt_allow_zero_date_vals` to 1.
`DECIMAL(p, s)` or `NUMERIC(p, s)`	If p is greater than 63 and s is greater than (p-63), the field definition is truncated to `DECIMAL(63, s-(p-63))`. If p is greater than 63 and s is less than or equal to (p-63), the definition is not supported.
`TIME`	By default, `IBMDB2I` only supports times in the range '00:00:00' to '23:59:59.' See the ibmdb2i_create_time_columns_as_tod option for more information.

- These MySQL statements are not supported by the `IBMDB2I` Engine:

  - `CACHE INDEX` and `LOAD INDEX INTO CACHE`

  - `HANDLER`

  - `CHECK TABLE`

  - `REPAIR TABLE`

  - `BACKUP-RESTORE TABLE`

- The `ucs2_spanish2_ci` and `utf8_spanish2_ci` collations are not supported by `IBMDB2I`. There are no plans to support these collations.

- The `ucs2_swedish_ci` and `utf8_swedish_ci` collations were added in MySQL 5.1.35. supported by `IBMDB2I`. As with other language-specific unicode collations, the support will be only be available on IBM i 6.1 and later releases.

14.7.8 Character sets and collations

DB2 for i only supports a single collation per index or foreign key constraint. A foreign key constraint must have the same collation as a primary key constraint, if one exists..

Character sets and collations supported by `IBMDB2I` are described in the list below. IBM i 6.1 is required for the most comprehensive collation support. Note that Chinese, Japanese, and Korean character sets are converted to UTF-16 for storage in DB2 for i; `utf8_general_ci` is converted to `UCS2` for storage in DB2 for i.

Table 14.10 Collation Compatibility in IBMDB2I and MySQL

14.7.9 Error codes and trouble-shooting information

Errors reported by the `IBMDB2I` engine may originate from two locations. Error values under 2500 originate in DB2 for i. Error values over 2500 originate in the storage engine itself. Occasionally, errors are reported by `IBMDB2I` but, due to the architecture of MySQL, cannot be directly exposed to MySQL client interfaces. In these cases, issuing a `SHOW ERRORS` statement or referring to the MySQL error log may be necessary to determine the cause of a failure. Errors which originate in DB2 for i are usually encountered in the DB2 for i SQL Server Mode job (QSQSRVR) which services the MySQL client connection; additional information about failures can often be found by looking in the job log of the associated QSQSRVR job.

Following is the list of codes and messages for errors that occur in DB2 for i that are reported by the `IBMDB2I` engine. %d and %s represent numbers and strings, respectively, that are replaced when the message is displayed.

Table 14.11 Error Codes from IBMDB2I

Error Code Number	Error Message Text
0	Successful
2016	Thread ID is too long
2017	Error creating a SPACE memory object

Error Code Number	Error Message Text
2018	Error creating a FILE memory object
2019	Error creating a SPACE synchronization token
2020	Error creating a FILE synchronization token
2021	See message %-.7s in joblog for job %-.6s/%-.10s/%-.10s.
2022	Error unlocking a synchronization token when closing a connection
2023	Invalid action specified for an 'object lock' request
2024	Invalid action specified for a savepoint request
2025	Partial keys are not supported with an ICU sort sequence
2026	Error retrieving an ICU sort key
2027	Error converting single-byte sort sequence to UCS-2
2028	An unsupported collation was specified
2029	Validation failed for referenced table of foreign key constraint
2030	Error extracting table for constraint information
2031	Error extracting referenced table for constraint information
2032	Invalid action specified for a 'commitment control' request
2033	Invalid commitment control isolation level specified on 'open' request
2034	Invalid file handle
2036	Invalid option specified for returning data on 'read' request
2037	Invalid orientation specified for 'read' request
2038	Invalid option type specified for 'read' request
2039	Invalid isolation level for starting commitment control
2040	Error unlocking a synchronization token in module QMYALC
2041	Length of space for returned format is not long enough
2042	SQL XA transactions are currently unsupported by this interface
2043	The associated QSQSRVR job was killed or ended unexpectedly.
2044	Error unlocking a synchronization token in module QMYSEI
2045	Error unlocking a synchronization token in module QMYSPO
2046	Error converting input CCSID from short form to long form
2048	Error getting associated CCSID for CCSID conversion
2049	Error converting a string from one CCSID to another
2050	Error unlocking a synchronization token
2051	Error destroying a synchronization token
2052	Error locking a synchronization token
2053	Error recreating a synchronization token
2054	A space handle was not specified for a constraint request
2055	An SQL cursor was specified for a delete request

Error Code Number	Error Message Text
2057	Error on delete request because current UFCB for connection is not open
2058	An SQL cursor was specified for an object initialization request
2059	An SQL cursor was specified for an object override request
2060	A space handle was not specified for an object override request
2061	An SQL cursor was specified for an information request
2062	An SQL cursor was specified for an object lock request
2063	An SQL cursor was specified for an optimize request
2064	A data handle was not specified for a read request
2065	A row number handle was not specified for a read request
2066	A key handle was not specified for a read request
2067	An SQL cursor was specified for an row estimation request
2068	A space handle was not specified for a row estimation request
2069	An SQL cursor was specified for a release record request
2070	A statement handle was not specified for an 'execute immediate' request
2071	A statement handle was not specified for a 'prepare open' request
2072	An SQL cursor was specified for an update request
2073	The UFCB was not open for read
2074	Error on update request because current UFCB for connection is not open
2075	A data handle was not specified for an update request
2076	An SQL cursor was specified for a write request
2077	A data handle was not specified for a write request
2078	An unknown function was specified on a process request
2079	A share definition was not specified for an 'allocate share' request
2080	A share handle was not specified for an 'allocate share' request
2081	A use count handle was not specified for an 'allocate share' request
2082	A 'records per key' handle was not specified for an information request
2083	Error resolving LOB address
2084	Length of a LOB space is too small
2085	An unknown function was specified for a server request
2086	Object authorization failed. See message %-.7s in joblog for job %-.6s/%-.10s/%-.10s. for more information.
2088	Error locking mutex on server
2089	Error unlocking mutex on server
2090	Error checking for RDB name in RDB Directory
2091	Error creating mutex on server
2094	Error unlocking mutex
2095	Error connecting to server job

Error Code Number	Error Message Text
2096	Error connecting to server job
2098	Function check occurred while registering parameter spaces. See job log.
2101	End of block
2102	The file has changed and might not be compatible with the MySQL table definition
2103	Error giving pipe to server job
2104	There are open object locks when attempting to deallocate
2105	There is no open lock
2108	The maximum value for the auto_increment data type was exceeded
2109	Error occurred closing the pipe
2110	Error occurred taking a descriptor for the pipe
2111	Error writing to pipe
2112	Server was interrupted
2113	No pipe descriptor exists for reuse
2114	Error occurred during an SQL prepare statement
2115	Error occurred during an SQL open
2122	An unspecified error was returned from the system.

Following is the list of error codes and messages that occur within the `IBMDB2I` storage engine.

Table 14.12 Error Codes and Messages in IBMDB2I

Error Code Number	Error Message Text
2501	Error opening codeset conversion from %.64s to %.64s (errno = %d). **Resolution:** Alter the table definition to specify a character set that is supported by the `IBMDB2I` engine.
2502	Invalid %-.10s name '%-.128s. **Resolution:** If a field name, ensure that it is less than the maximum length of 126 characters.If an index name, ensure that the length of the index name plus the length of the table name is less than 121 characters.
2503	Unsupported move from '%-.128s' to '%-.128s' on RENAME TABLE statement. **Resolution:** Moving a table from one schema to another is not supported by the `IBMDB2I` engine. Create a new table in the 'to' schema, copy the data to the new table, and then drop the old table.
2504	The %-.64s character set is not supported. **Resolution:** Try using another character set.
2505	Auto_increment is not allowed for a partitioned table. **Resolution:** Remove the auto_increment attribute from the table or do not partition the table.
2506	Character set conversion error due to unknown encoding scheme %d. **Resolution:** Alter the table definition to ensure that character sets assigned to columns are supported by the `IBMDB2I` engine.

Error Code Number	Error Message Text
2508	Table '%-.128s' was not found by the storage engine. **Resolution:** A table definition exists in MySQL, but the correspondingtable in DB2 for i is not found. Delete the MySQL table or restore the DB2 table.
2509	Could not resolve to %-.128s in library %-.10s type %-.10s (errno = %d). **Resolution:** Restore the missing IBM i object to the system.
2510	Error on _PGMCALL for program %-.10s in library %-.10s (error = %d). **Resolution:** This is an internal error.
2511	Error on _ILECALL for API '%.128s' (error = %d). **Resolution:** This is an internal error.
2512	Error in iconv() function during character set conversion (errno = %d). **Resolution:** Ensure the text being inserted contains only valid code points for the associated character set. This may be caused by using ENCRYPT or COMPRESS on a text field, resulting in binary data containing invalid characters.
2513	Error from Get Encoding Scheme (QTQGESP) API: %d, %d, %d **Resolution:** This is an internal error.
2514	Error from Get Related Default CCSID (QTQGRDC) API: %d, %d, %d. **Resolution:** This is an internal error.
2515	Data out of range for column '%.192s'. **Resolution:** DB2 for i does not support a zero value for DATE and DATETIME data types. Specify a new value for the column.
2516	Schema name '%.128s' exceeds maximum length of %d characters. **Resolution:** Change the schema name so that its length does not exceed the maximum. For mixed case or lowercase names, permit 2 characters for outer quotation marks.
2517	Multiple collations not supported in a single index. **Resolution:** DB2 for i only supports sort sequences at the table or index level, so all character-based columns in the primary key or index must be using the same collation. Alter the table definition so that all columns use the same collation.
2518	Sort sequence was not found. **Resolution:** Alter the table to use a collation that is supported by the `IBMDB2I` engine.
2519	One or more characters in column %.128s were substituted during conversion. **Resolution:** This is a warning that during the conversion of data from MySQL to DB2 some characters were replaced with substitute characters.
2520	A decimal column exceeded the maximum precision. Data may be truncated. **Resolution:** A decimal column specified on a CREATE TABLE or ALTER TABLE command has greater precision than DB2 permits. Data stored in this column may be truncated. Change the column specification to have a precision less than or equal to 63.
2521	Some data returned by DB2 for table %s could not be converted for MySQL. **Resolution:** This is a warning that some data could not be converted from DB2 to MySQL. Data was likely inserted into the table using DB2 interfaces that is valid data for DB2 but is invalid for MySQL.
2523	Column %.128s contains characters that cannot be converted. **Resolution:** An error occurred converting data from the MySQL character set to the associated DB2 coded character set identifier (CCSID).Omit the incompatible characters or alter the table to specify a different character set for the column.
2524	An invalid name was specified for ibmdb2i_rdb_name. **Resolution:** Specify a valid relational database (RDB) name.

Error Code Number	Error Message Text
2525	A duplicate key was encountered for index '%.128s'. **Resolution:** : Specify a unique key value for the row. Generally, this error occurs if a unique constraint or index has been applied to the table from a non-MySQL interface.
2528	Some attribute(s) defined for column '%.128s' may not be honored by accesses from DB2.

14.8 The MERGE Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. "Identical" means that all tables have identical column and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See Section 4.6.5, "`myisampack` — Generate Compressed, Read-Only MyISAM Tables". Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

An alternative to a `MERGE` table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the `MyISAM` storage engine. For more information, see Chapter 18, *Partitioning*.

When you create a `MERGE` table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the underlying `MyISAM` tables that should be used as one. The tables do not have to be in the same database as the `MERGE` table.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `DELETE`, and `UPDATE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

Note

The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of `DROP TABLE` with a `MERGE` table drops only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` option that indicates which `MyISAM` tables to use. You can optionally specify an `INSERT_METHOD` option to control how inserts into the `MERGE` table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no `INSERT_METHOD` option or if you specify it with a value of `NO`, inserts into the `MERGE` table are not permitted and attempts to do so result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
    ->    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->    message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
    ->    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->    message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
```

```
mysql> CREATE TABLE total (
    ->     a INT NOT NULL AUTO_INCREMENT,
    ->     message CHAR(20), INDEX(a))
    ->     ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column `a` is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a `UNIQUE` index in the underlying tables should be indexed in the `MERGE` table but not as a `UNIQUE` index.)

After creating the `MERGE` table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+---+---------+
| a | message |
+---+---------+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+---+---------+
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- `DROP` the `MERGE` table and re-create it.

- Use `ALTER TABLE` *tbl_name* `UNION=(...)` to change the list of underlying tables.

  Beginning with MySQL 5.1.24, it is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new `MERGE` tables with `CREATE TABLE ... LIKE`.

As of MySQL 5.1.15, the underlying table definitions and indexes must conform more closely than previously to the definition of the `MERGE` table. Conformance is checked when a table that is part of a `MERGE` table is opened, not when the `MERGE` table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a `MERGE` may cause a failure when the `MERGE` table is accessed. The conformance checks applied to each table are:

- The underlying table and the `MERGE` table must have the same number of columns.

- The column order in the underlying table and the `MERGE` table must match.

- Additionally, the specification for each corresponding column in the parent `MERGE` table and the underlying tables are compared and must satisfy these checks:

  - The column type in the underlying table and the `MERGE` table must be equal.

  - The column length in the underlying table and the `MERGE` table must be equal.

  - The column of the underlying table and the `MERGE` table can be `NULL`.

- The underlying table must have at least as many indexes as the `MERGE` table. The underlying table may have more indexes than the `MERGE` table, but cannot have fewer.

> **Note**
>
> A known issue exists where indexes on the same columns must be in identical order, in both the `MERGE` table and the underlying `MyISAM` table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the `MERGE` table must be the same.

- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the `MERGE` table must be the same.

- For each index part:

  - Index part lengths must be equal.

  - Index part types must be equal.

  - Index part languages must be equal.

  - Check whether index parts can be `NULL`.

For information about the table checks applied prior to MySQL 5.1.15, see Section 14.8.2, "MERGE Table Problems".

As of MySQL 5.1.20, if a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

Additional Resources

- A forum dedicated to the `MERGE` storage engine is available at http://forums.mysql.com/list.php?93.

14.8.1 MERGE Table Advantages and Disadvantages

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.

- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table structured this way could be much faster than using a single large table.

- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.

- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a `MERGE` table than to repair a single large table.

- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are *very* fast to create or remap. (You must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)

- If you have a set of tables from which you create a large table on demand, you can instead create a `MERGE` table from them on demand. This is much faster and saves a lot of disk space.

- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.

- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.

- Some `MyISAM` features are unavailable in `MERGE` tables. For example, you cannot create `FULLTEXT` indexes on `MERGE` tables. (You can create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)

- If the `MERGE` table is nontemporary, all underlying `MyISAM` tables must be nontemporary. If the `MERGE` table is temporary, the `MyISAM` tables can be any mix of temporary and nontemporary.

- `MERGE` tables use more file descriptors than `MyISAM` tables. If 10 clients are using a `MERGE` table that maps to 10 tables, the server uses (10 × 10) + 10 file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)

- Index reads are slower. When you read an index, the `MERGE` storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the `MERGE` storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes `MERGE` indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see Section 13.8.2, "EXPLAIN Syntax".

14.8.2 MERGE Table Problems

The following are known problems with `MERGE` tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child MyISAM tables.

  From versions 5.1.23, MERGE children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the MyISAM tables corrupted them.

- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.

- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.

- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.

- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:

  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.

  - If `REPLACE` detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

  Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.

- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

  The unexpected results include the possibility that the operation on the `MERGE` table will report table corruption. If this occurs after one of the named operations on the underlying `MyISAM` tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.

- As of MySQL 5.1.15, the definition of the `MyISAM` tables and the `MERGE` table are checked when the tables are accessed (for example, as part of a `SELECT` or `INSERT` statement). The checks ensure that the definitions of the tables and the parent `MERGE` table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.

  Prior to MySQL 5.1.15, table checks are applied as follows:

  - When you create or alter `MERGE` table, there is no check to ensure that the underlying tables are existing `MyISAM` tables and have identical structures. When the `MERGE` table is used, MySQL checks that the row length for all mapped tables is equal, but this is not foolproof. If you create a `MERGE` table from dissimilar `MyISAM` tables, you are very likely to run into strange problems.

  - Similarly, if you create a `MERGE` table from non-`MyISAM` tables, or if you drop an underlying table or alter it to be a non-`MyISAM` table, no error for the `MERGE` table occurs until later when you attempt to use it.

  - Because the underlying `MyISAM` tables need not exist when the `MERGE` table is created, you can create the tables in any order, as long as you do not use the `MERGE` table until all of its underlying tables are in place. Also, if you can ensure that a `MERGE` table will not be used during a given period, you can perform maintenance operations on the underlying tables, such as backing up or restoring them, altering them, or dropping and recreating them. It is not necessary to redefine the `MERGE` table temporarily to exclude the underlying tables while you are operating on them.

- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE` to add a nonunique index on the `MERGE` table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.

- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the `MyISAM` storage engine. Confirm that all of these tables are `MyISAM`.

- The maximum number of rows in a `MERGE` table is 2^{64} (~1.844E+19; the same as for a `MyISAM` table), provided that the server was built using the `--with-big-tables` option. (All standard MySQL 5.1 standard binaries are built with this option; for more information, see Section 2.11.4, "MySQL Source-Configuration Options".) It is not possible to merge multiple `MyISAM` tables into a single `MERGE` table that would have more than this number of rows.

- The `MERGE` storage engine does not support `INSERT DELAYED` statements.

- Use of underlying `MyISAM` tables of differing row formats with a parent `MERGE` table is currently known to fail. See Bug #32364.

- As of MySQL 5.1.23, you cannot change the union list of a nontemporary `MERGE` table when `LOCK TABLES` is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary `MERGE` table.

- As of MySQL 5.1.23, you cannot create a `MERGE` table with `CREATE ... SELECT`, neither as a temporary `MERGE` table, nor as a nontemporary `MERGE` table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: `tbl_name` is not `BASE TABLE`.

- In some cases, differing `PACK_KEYS` table option values among the `MERGE` and underlying tables cause unexpected results if the underlying tables contain `CHAR` or `BINARY` columns. As a workaround, use `ALTER TABLE` to ensure that all involved tables have the same `PACK_KEYS` value. (Bug #50646)

14.9 The MEMORY Storage Engine

The `MEMORY` storage engine (formerly known as `HEAP`) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

Table 14.13 `MEMORY` Storage Engine Features

Storage limits	RAM	Transactions	No	Locking granularity	Table
MVCC	No	Geospatial data type support	No	Geospatial indexing support	No
B-tree indexes	Yes	T-tree indexes	No	Hash indexes	Yes
Full-text search indexes	No	Clustered indexes	No	Data caches	N/A

Index caches	N/A	Compressed data	No	Encrypted data[a]	Yes
Cluster database support	No	Replication support[b]	Yes	Foreign key support	No
Backup / point-in-time recovery[c]	Yes	Query cache support	Yes	Update statistics for data dictionary	Yes

[a]Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

[b]Implemented in the server, rather than in the storage engine.

[c]Implemented in the server, rather than in the storage engine.

When to Use MEMORY or MySQL Cluster. Developers looking to deploy applications that use the `MEMORY` storage engine for important, highly available, or frequently updated data should consider whether MySQL Cluster is a better choice. A typical use case for the `MEMORY` engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in `MEMORY` tables is lost.

- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.

- A read-only or read-mostly data access pattern (limited updates).

MySQL Cluster offers the same features as the `MEMORY` engine with higher performance levels, and provides additional features not available with `MEMORY`:

- Row-level locking and multiple-thread operation for low contention between clients.

- Scalability even with statement mixes that include writes.

- Optional disk-backed operation for data durability.

- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.

- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.

- Support for variable-length data types (including `BLOB` and `TEXT`) not supported by `MEMORY`.

For a white paper with more detailed comparison of the `MEMORY` storage engine and MySQL Cluster, see Scaling Web Services with MySQL Cluster: An Alternative to the MySQL Memory Storage Engine. This white paper includes a performance study of the two technologies and a step-by-step guide describing how existing `MEMORY` users can migrate to MySQL Cluster.

Performance Characteristics

`MEMORY` performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for `MEMORY` tables, they are not necessarily faster than `InnoDB` tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of `MEMORY` tables from multiple sessions.

Depending on the kinds of queries performed on a `MEMORY` table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-

tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

Physical Characteristics of MEMORY Tables

The `MEMORY` storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of `.frm`.

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.

- `MEMORY` tables use a fixed-length row-storage format. Variable-length types such as `VARCHAR` are stored using a fixed length.

- `MEMORY` tables cannot contain `BLOB` or `TEXT` columns.

- `MEMORY` includes support for `AUTO_INCREMENT` columns.

- Non-`TEMPORARY MEMORY` tables are shared among all clients, just like any other non-`TEMPORARY` table.

DDL Operations for MEMORY Tables

To create a `MEMORY` table, specify the clause `ENGINE=MEMORY` on the `CREATE TABLE` statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, `MEMORY` tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in `MEMORY` tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a `MEMORY` table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
    ->     SELECT ip,SUM(downloads) AS down
    ->     FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of `MEMORY` tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for `MEMORY` tables, change the value of this variable. The value in effect for `CREATE TABLE`, or a subsequent `ALTER TABLE` or `TRUNCATE TABLE`, is the value used for the life of the table. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

Indexes

The `MEMORY` storage engine supports both `HASH` and `BTREE` indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```
CREATE TABLE lookup
    (id INT, INDEX USING HASH (id))
    ENGINE = MEMORY;
CREATE TABLE lookup
    (id INT, INDEX USING BTREE (id))
    ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see Section 8.3.1, "How MySQL Uses Indexes".

MEMORY tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a MEMORY table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a BTREE index to avoid this problem.

MEMORY tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain NULL values.

User-Created and Temporary Tables

MEMORY table contents are stored in memory, which is a property that MEMORY tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that MEMORY tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in Section 8.4.4, "Internal Temporary Table Use in MySQL".

- User-created MEMORY tables are never converted to disk tables.

Loading Data

To populate a MEMORY table when the MySQL server starts, you can use the --init-file option. For example, you can put statements such as INSERT INTO ... SELECT or LOAD DATA INFILE into this file to load the table from a persistent data source. See Section 5.1.3, "Server Command Options", and Section 13.2.6, "LOAD DATA INFILE Syntax".

For loading data into MEMORY tables accessed by other sessions concurrently, MEMORY supports INSERT DELAYED. See Section 13.2.5.2, "INSERT DELAYED Syntax".

MEMORY Tables and Replication

A server's MEMORY tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave MEMORY tables, when a MEMORY table is used on a master for the first time since it was started, a DELETE statement is written to the master's binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master's restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the --init-file option to populate the MEMORY table on the master at startup.

Managing Memory Use

The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a `MEMORY` table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a `MEMORY` table when you no longer require its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at http://forums.mysql.com/list.php?92.

14.10 The EXAMPLE Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `configure` with the `--with-example-storage-engine` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
                    have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

14.11 The FEDERATED Storage Engine

The `FEDERATED` storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local `FEDERATED` table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the `FEDERATED` storage engine if you build MySQL from source, invoke `configure` with the `--with-federated-storage-engine` option.

Beginning with MySQL 5.1.26, the `FEDERATED` storage engine is not enabled by default in the running server; to enable `FEDERATED`, you must start the MySQL server binary using the `--federated` option.

To examine the source for the `FEDERATED` engine, look in the `storage/federated` directory of a MySQL source distribution.

14.11.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as `MyISAM`, `CSV` or `InnoDB`), the table consists of the table definition and the associated data. When you create a `FEDERATED` table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A `FEDERATED` table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the `.frm` file) and the associated table. The table type of the remote table may be any type supported by the remote `mysqld` server, including `MyISAM` or `InnoDB`.

- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the `.frm` file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a `FEDERATED` table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote

server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a `FEDERATED` table setup is shown in Figure 14.1, "FEDERATED Table Structure".

Figure 14.1 FEDERATED Table Structure
When a client issues an SQL statement that refers to a `FEDERATED` table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the `FEDERATED` table has and constructs an appropriate SQL statement that refers to the remote table.

2. The statement is sent to the remote server using the MySQL client API.

3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).

4. If the statement produces a result set, each column is converted to internal storage engine format that the `FEDERATED` engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

14.11.2 How to Create FEDERATED Tables

To create a `FEDERATED` table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.

2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
    id       INT(20) NOT NULL AUTO_INCREMENT,
```

```
    name   VARCHAR(32) NOT NULL DEFAULT '',
    other  INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;
```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the CONNECTION, or you can use an existing connection that you have previously created using the CREATE SERVER statement.

> **Important**
>
> When you create the local table it *must* have an identical field definition to the remote table.

> **Note**
>
> You can improve the performance of a FEDERATED table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the WHERE clause and will be sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

14.11.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the CONNECTION string after the engine type in a CREATE TABLE statement. For example:

```
CREATE TABLE federated_table (
    id     INT(20) NOT NULL AUTO_INCREMENT,
    name   VARCHAR(32) NOT NULL DEFAULT '',
    other  INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

> **Note**
>
> CONNECTION replaces the COMMENT used in some previous versions of MySQL.

The CONNECTION string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server remote_host, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- *scheme*: A recognized connection protocol. Only `mysql` is supported as the *scheme* value at this point.

- *user_name*: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.

- *password*: (Optional) The corresponding password for *user_name*.

- *host_name*: The host name or IP address of the remote server.

- *port_num*: (Optional) The port number for the remote server. The default is 3306.

- *db_name*: The name of the database holding the remote table.

- *tbl_name*: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

14.11.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of `FEDERATED` tables on the same server, or if you want to simplify the process of creating `FEDERATED` tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER
server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The *server_name* is used in the connection string when creating a new `FEDERATED` table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a `FEDERATED` table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (
    id      INT(20) NOT NULL AUTO_INCREMENT,
    name    VARCHAR(32) NOT NULL DEFAULT '',
    other   INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
```

```
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see Section 13.1.16, "CREATE SERVER Syntax".

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Description	CONNECTION string	CREATE SERVER option	mysql.servers column
Connection scheme	scheme	wrapper_name	Wrapper
Remote user	user_name	USER	Username
Remote password	password	PASSWORD	Password
Remote host	host_name	HOST	Host
Remote port	port_num	PORT	Port
Remote database	db_name	DATABASE	Db

14.11.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server.

- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.

- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.

- A `FEDERATED` table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

  Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a `FEDERATED` table since the index definition from an equivalent `MyISAM` or other table may not be supported. For example, creating a `FEDERATED` table with an index prefix on `VARCHAR`, `TEXT` or `BLOB` columns will fail. The following definition in `MyISAM` is valid:

  ```
  CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
  ```

  The key prefix in this example is incompatible with the `FEDERATED` engine, and the equivalent statement will fail:

  ```
  CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
    CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
  ```

  If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.

- The `FEDERATED` storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, and indexes. It does not support `ALTER TABLE`, or any Data Definition Language statements that directly affect the structure of the table, other than `DROP TABLE`. The current implementation does not use prepared statements.

- `FEDERATED` accepts `INSERT ... ON DUPLICATE KEY UPDATE` statements, but if a duplicate-key violation occurs, the statement fails with an error.

- Performance on a `FEDERATED` table when performing bulk inserts (for example, on a `INSERT INTO ... SELECT ...` statement) is slower than with other table types because each selected row is treated as an individual `INSERT` statement on the `FEDERATED` table.

- Transactions are not supported.

- Before MySQL 5.1.21, for a multiple-row insert into a `FEDERATED` table that refers to a remote transactional table, if the insert failed for a row due to constraint failure, the remote table would contain a partial commit (the rows preceding the failed one) instead of rolling back the statement completely. This occurred because the rows were treated as individual inserts.

  As of MySQL 5.1.21, `FEDERATED` performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:

  - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.

  - Bulk-insert handling does not occur for `INSERT ... ON DUPLICATE KEY UPDATE`.

- There is no way for the `FEDERATED` engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.

- When using a `CONNECTION` string, you cannot use an '@' character in the password. You can get round this limitation by using the `CREATE SERVER` statement to create a server connection.

- The `insert_id` and `timestamp` options are not propagated to the data provider.

- Any `DROP TABLE` statement issued against a `FEDERATED` table drops only the local table, not the remote table.

- `FEDERATED` tables do not work with the query cache.

- User-defined partitioning is not supported for `FEDERATED` tables. Beginning with MySQL 5.1.15, it is no longer possible to create such tables at all.

14.11.4 FEDERATED Storage Engine Resources

The following additional resources are available for the `FEDERATED` storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at http://forums.mysql.com/list.php? 105.

14.12 The ARCHIVE Storage Engine

The `ARCHIVE` storage engine is used for storing large amounts of data without indexes in a very small footprint.

Table 14.14 `ARCHIVE` Storage Engine Features

Storage limits	None	Transactions	No	Locking granularity	Row
MVCC	No	Geospatial data type support	Yes	Geospatial indexing support	No
B-tree indexes	No	T-tree indexes	No	Hash indexes	No
Full-text search indexes	No	Clustered indexes	No	Data caches	No
Index caches	No	Compressed data	Yes	Encrypted data[a]	Yes
Cluster database support	No	Replication support[b]	Yes	Foreign key support	No
Backup / point-in-time recovery[c]	Yes	Query cache support	Yes	Update statistics for data dictionary	Yes

[a]Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.
[b]Implemented in the server, rather than in the storage engine.
[c]Implemented in the server, rather than in the storage engine.

The `ARCHIVE` storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-archive-storage-engine` option.

To examine the source for the `ARCHIVE` engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the `ARCHIVE` storage engine is available with the `SHOW ENGINES` statement.

When you create an `ARCHIVE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of `.ARZ`. (Prior to MySQL 5.1.15, a metadata file with an extension of `.ARM` is created as well.) An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT`, `REPLACE`, and `SELECT`, but not `DELETE` or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see Section 11.5.1, "Spatial Data Types"). The `ARCHIVE` engine uses row-level locking.

As of MySQL 5.1.6, the `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or nonunique index. Attempting to create an index

on any other column results in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

`ARCHIVE` does not support inserting a value into an `AUTO_INCREMENT` column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

As of MySQL 5.1.6, the `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading. Formerly, the following two statements had the same cost, but as of 5.1.6, the second is much more efficient than the first:

```
SELECT a, b, blob_col FROM archive_table;
SELECT a, b FROM archive_table;
```

Storage: Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see http://www.zlib.net/). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur, unless the only insertions that have come in were `INSERT DELAYED` (those flush as necessary). See Section 13.2.5.2, "INSERT DELAYED Syntax".

- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See Section 13.7.2.5, "OPTIMIZE TABLE Syntax", Section 13.7.2.6, "REPAIR TABLE Syntax", and Section 13.7.5.38, "SHOW TABLE STATUS Syntax".

> **Warning**
>
> **Known issue**: After a binary upgrade to MySQL 5.1 from a MySQL 5.0 installation that contains `ARCHIVE` tables:
>
> - Before MySQL 5.1.42, accessing those tables will cause the server to crash, even if you have run `mysql_upgrade` or `CHECK TABLE ... FOR UPGRADE`.
>
> - As of MySQL 5.1.42, the server will not open 5.0 `ARCHIVE` tables at all.
>
> In either case, the solution is to use `mysqldump` to dump all 5.0 `ARCHIVE` tables before upgrading, and reload them into MySQL 5.1 after upgrading. This problem is fixed in MySQL 5.6.4: The server can open `ARCHIVE` tables created in MySQL 5.0. However, it remains the recommended upgrade procedure to dump 5.0 `ARCHIVE` tables before upgrading and reload after upgrading.

Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at http://forums.mysql.com/list.php?112.

14.13 The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

To enable the `CSV` storage engine if you build MySQL from source, invoke `configure` with the `--with-csv-storage-engine` option.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
    -> ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
+------+------------+
| i    | c          |
+------+------------+
|    1 | record one |
|    2 | record two |
+------+------------+
2 rows in set (0.00 sec)
```

Starting with MySQL 5.1.9, creating a CSV table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

14.13.1 Repairing and Checking CSV Tables

Functionality introduced in version 5.1.9

The CSV storage engines supports the `CHECK` and `REPAIR` statements to verify and if possible repair a damaged CSV table.

When running the `CHECK` statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+--------------+-------+----------+----------+
```

```
| Table        | Op     | Msg_type | Msg_text |
+--------------+-------+----------+----------+
| test.csvtest | check | status   | OK       |
+--------------+-------+----------+----------+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+--------------+-------+----------+----------+
| Table        | Op    | Msg_type | Msg_text |
+--------------+-------+----------+----------+
| test.csvtest | check | error    | Corrupt  |
+--------------+-------+----------+----------+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+--------------+-------+----------+---------------------------+
| Table        | Op    | Msg_type | Msg_text                  |
+--------------+-------+----------+---------------------------+
| test.csvtest | check | warning  | Table is marked as crashed |
| test.csvtest | check | status   | OK                        |
+--------------+-------+----------+---------------------------+
2 rows in set (0.08 sec)
```

To repair a table you can use `REPAIR`, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+--------------+--------+----------+----------+
| Table        | Op     | Msg_type | Msg_text |
+--------------+--------+----------+----------+
| test.csvtest | repair | status   | OK       |
+--------------+--------+----------+----------+
1 row in set (0.02 sec)
```

> **Warning**
>
> During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

14.13.2 CSV Limitations

The `CSV` storage engine does not support indexing.

Partitioning is not supported for tables using the `CSV` storage engine. Beginning with MySQL 5.1.12, it is no longer possible to create partitioned `CSV` tables. (See Bug #19307)

Beginning with MySQL 5.1.23, all tables that you create using the `CSV` storage engine must have the `NOT NULL` attribute on all columns. However, for backward compatibility, you can continue to use tables with nullable columns that were created in previous MySQL releases. (Bug #32050)

14.14 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a "black hole" that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the BLACKHOLE storage engine if you build MySQL from source, invoke configure with the --with-blackhole-storage-engine option.

To examine the source for the BLACKHOLE engine, look in the sql directory of a MySQL source distribution.

When you create a BLACKHOLE table, the server creates a table format file in the database directory. The file begins with the table name and has an .frm extension. There are no other files associated with the table.

The BLACKHOLE storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the BLACKHOLE storage engine is available with the SHOW ENGINES statement.

Inserts into a BLACKHOLE table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

> **Note**
>
> When using the row based format for the binary log, updates and deletes are skipped, and neither logged nor applied. For this reason, you should use STATEMENT for the binary logging format, and not ROW or MIXED.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a "dummy" slave process whose default storage engine is BLACKHOLE, depicted as follows:
The master writes to its binary log. The "dummy" `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See Section 16.1.3, "Replication and Binary Logging Options and Variables".) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.

- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.

- `BLACKHOLE` is essentially a "no-op" storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` storage engine does not support `INSERT DELAYED`, `LOCK TABLES`, or `UNLOCK TABLES` statements prior to MySQL 5.1.19.

As of MySQL 5.1.4, the `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.

2. On a slave the same table exists but using the MyISAM engine.

3. Inserts are performed into the master's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

Column Filtering

When using row-based replication, (`binlog_format=ROW`), a slave where the last columns are missing from a table is supported, as described in the section Section 16.4.1.10, "Replication with Differing Table Definitions on Master and Slave".

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.

2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how master table filtering is achieved - by using the `BLACKHOLE` engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the master is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,
                 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

Chapter 15 High Availability and Scalability

Table of Contents

Data is the currency of today's web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no "one size fits all" approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. **Availability** refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Scalability refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.

- The type of application being deployed.

- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: Chapter 16, *Replication*.

- MySQL Fabric. Learn more: MySQL Fabric.

- MySQL Cluster. Learn more: Chapter 17, *MySQL Cluster NDB 6.1 - 7.1*.

- Oracle Clusterware Agent for MySQL. Learn more about Oracle Clusterware.

- MySQL with Solaris Cluster. Learn more about Solaris Cluster.

Further options are available using third-party solutions.

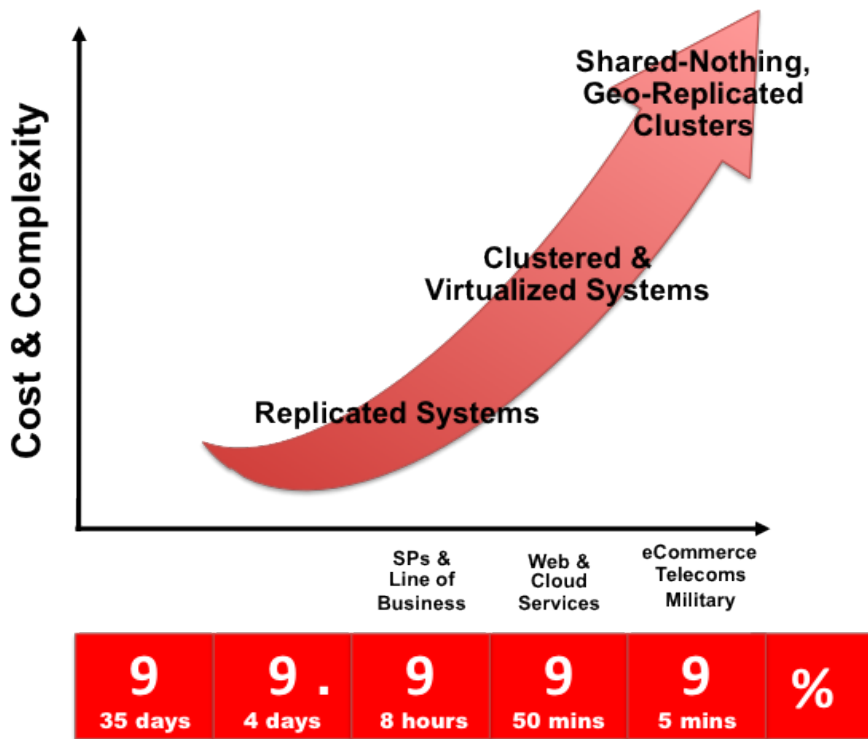
Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.

- Clustered & Virtualized Systems.

- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

Figure 15.1 Tradeoffs: Cost and Complexity versus Availability


The following table compares the HA and Scalability capabilities of the various MySQL solutions:

Table 15.1 Feature Comparison of MySQL HA Solutions

Requirement	MySQL Replication	MySQL Cluster
Availability		
Platform Support	All Supported by MySQL Server (http://www.mysql.com/	All Supported by MySQL Cluster (http://www.mysql.com/support/supportedplatforms/cluster.html)

Requirement	MySQL Replication	MySQL Cluster
	support/supportedplatforms/database.html)	
Automated IP Failover	No	Depends on Connector and Configuration
Automated Database Failover	No	Yes
Automatic Data Resynchronization	No	Yes
Typical Failover Time	User / Script Dependent	1 Second and Less
Synchronous Replication	No, Asynchronous and Semisynchronous	Yes
Shared Storage	No, Distributed	No, Distributed
Geographic redundancy support	Yes	Yes, via MySQL Replication
Update Schema On-Line	No	Yes
Scalability		
Number of Nodes	One Master, Multiple Slaves	255
Built-in Load Balancing	Reads, via MySQL Replication	Yes, Reads and Writes
Supports Read-Intensive Workloads	Yes	Yes
Supports Write-Intensive Workloads	Yes, via Application-Level Sharding	Yes, via Auto-Sharding
Scale On-Line (add nodes, repartition, etc.)	No	Yes

15.1 Using MySQL within an Amazon EC2 Instance

The Amazon Elastic Compute Cloud (EC2) service provides virtual servers that you can build and deploy to run a variety of different applications and services, including MySQL. The EC2 service is based around the Xen framework, supporting x86, Linux based, platforms with individual instances of a virtual machine referred to as an Amazon Machine Image (AMI). You have complete (root) access to the AMI instance that you create, enabling you to configure and install your AMI in any way you choose.

To use EC2, you create an AMI based on the configuration and applications that you intend to use, and upload the AMI to the Amazon Simple Storage Service (S3). From the S3 resource, you can deploy one or more copies of the AMI to run as an instance within the EC2 environment. The EC2 environment provides management and control of the instance and contextual information about the instance while it is running.

Because you can create and control the AMI, the configuration, and the applications, you can deploy and create any environment you choose. This includes a basic MySQL server in addition to more extensive replication, HA and scalability scenarios that enable you to take advantage of the EC2 environment, and the ability to deploy additional instances as the demand for your MySQL services and applications grow.

To aid the deployment and distribution of work, three different Amazon EC2 instances are available, small (identified as `m1.small`), large (`m1.large`) and extra large (`m1.xlarge`). The different types provide different levels of computing power measured in EC2 computer units (ECU). A summary of the different instance configurations is shown in the following table.

EC2 Attribute	Small	Large	Extra Large
Platform	32-bit	64-bit	64-bit

EC2 Attribute	Small	Large	Extra Large
CPU cores	1	2	4
ECUs	1	4	8
RAM	1.7GB	7.5GB	15GB
Storage	150GB	840GB	1680GB
I/O Performance	Medium	High	High

The typical model for deploying and using MySQL within the EC2 environment is to create a basic AMI that you can use to hold your database data and application. Once the basic environment for your database and application has been created you can then choose to deploy the AMI to a suitable instance. Here the flexibility of having an AMI that can be re-deployed from the small to the large or extra large EC2 instance makes it easy to upgrade the hardware environment without rebuilding your application or database stack.

To get started with MySQL on EC2, including information on how to set up and install MySQL within an EC2 installation and how to port and migrate your data to the running instance, see Section 15.1.1, "Setting Up MySQL on an EC2 AMI".

For tips and advice on how to create a scalable EC2 environment using MySQL, including guides on setting up replication, see Section 15.1.3, "Deploying a MySQL Database Using EC2".

15.1.1 Setting Up MySQL on an EC2 AMI

There are many different ways of setting up an EC2 AMI with MySQL, including using any of the pre-configured AMIs supplied by Amazon.

The default *Getting Started* AMI provided by Amazon uses Fedora Core 4, and you can install MySQL by using `yum`:

```
shell> yum install mysql
```

This installs both the MySQL server and the Perl DBD::mysql driver for the Perl DBI API.

Alternatively, you can use one of the AMIs that include MySQL within the standard installation.

Finally, you can also install a standard version of MySQL downloaded from the MySQL Web site. The installation process and instructions are identical to any other installation of MySQL on Linux. See Chapter 2, *Installing and Upgrading MySQL*.

The standard configuration for MySQL places the data files in the default location, `/var/lib/mysql`. The default data directory on an EC2 instance is `/mnt` (although on the large and extra large instance you can alter this configuration). You must edit `/etc/my.cnf` to set the `datadir` option to point to the larger storage area.

> **Important**
>
> The first time you use the main storage location within an EC2 instance it needs to be initialized. The initialization process starts automatically the first time you write to the device. You can start using the device right away, but the write performance of the new device is significantly lower on the initial writes until the initialization process has finished.
>
> To avoid this problem when setting up a new instance, you should start the initialization process before populating your MySQL database. One way to do this is to use `dd` to write to the file system:

```
root-shell> dd if=/dev/zero of=initialize bs=1024M count=50
```

The preceding creates a 50GB on the file system and starts the initialization process. Delete the file once the process has finished.

The initialization process can be time-consuming. On the small instance, initialization takes between two and three hours. For the large and extra large drives, the initialization can be 10 or 20 hours, respectively.

In addition to configuring the correct storage location for your MySQL data files, also consider setting the following other settings in your instance before you save the instance configuration for deployment:

• Set the MySQL server ID, so that when you use it for replication, the ID information is set correctly.

• Enabling binary logging, so that replication can be initialized without starting and stopping the server.

• Set the caching and memory parameters for your storage engines. There are no limitations or restrictions on what storage engines you use in your EC2 environment. Choose a configuration, possibly using one of the standard configurations provided with MySQL appropriate for the instance on which you expect to deploy. The large and extra large instances have RAM that can be dedicated to caching. Be aware that if you choose to install `memcached` on the servers as part of your application stack you must ensure there is enough memory for both MySQL and `memcached`.

Once you have configured your AMI with MySQL and the rest of your application stack, save the AMI so that you can deploy and reuse the instance.

Once you have your application stack configured in an AMI, populating your MySQL database with data should be performed by creating a dump of your database using `mysqldump`, transferring the dump to the EC2 instance, and then reloading the information into the EC2 instance database.

Before using your instance with your application in a production situation, be aware of the limitations of the EC2 instance environment. See Section 15.1.2, "EC2 Instance Limitations". To begin using your MySQL AMI, consult the notes on deployment. See Section 15.1.3, "Deploying a MySQL Database Using EC2".

15.1.2 EC2 Instance Limitations

Be aware of the following limitations of the EC2 instances before deploying your applications. Although these shouldn't affect your ability to deploy within the Amazon EC2 environment, they may alter the way you setup and configure your environment to support your application.

• Data stored within instances is not persistent. If you create an instance and populate the instance with data, then the data only remains in place while the machine is running, and does not survive a reboot. If you shut down the instance, any data it contained is lost.

To ensure that you do not lose information, take regular backups using `mysqldump`. If the data being stored is critical, consider using replication to keep a "live" backup of your data in the event of a failure. When creating a backup, write the data to the Amazon S3 service to avoid the transfer charges applied when copying data offsite.

• EC2 instances are not persistent. If the hardware on which an instance is running fails, the instance is shut down. This can lead to loss of data or service.

However, if you use EBS, you can attach an EBS storage volume to an EC2 instance, and that EBS volume is persistent. Like a disk, an EBS volume can fail, but it is possible to create point-in-time snapshots of the volume. Snapshots are persisted to Amazon S3 and can be used to restore data in the event of volume failure.

- To replicate your EC2 instances to a non-EC2 environment, be aware of the transfer costs to and from the EC2 service. Data transfer between different EC2 instances is free, so using replication within the EC2 environment does not incur additional charges.

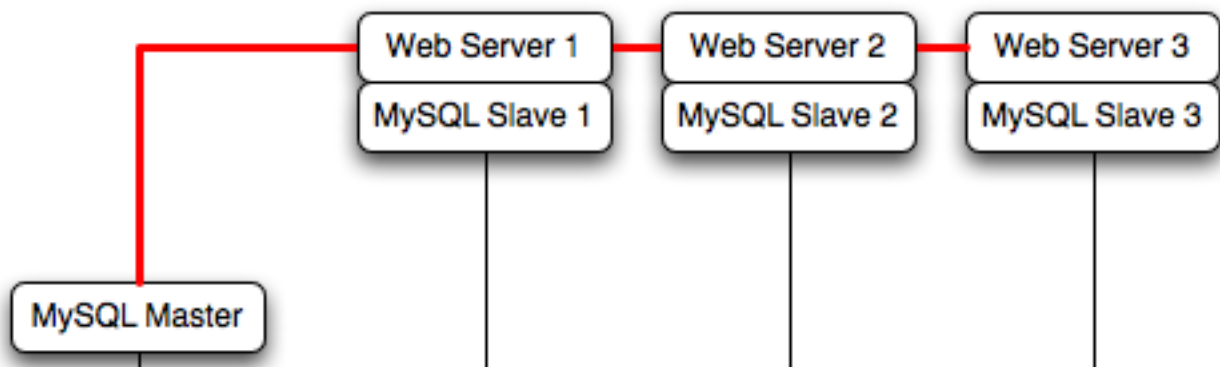
- Certain HA features are either not directly supported, or have limiting factors or problems that could reduce their utility. For example, using DRBD or MySQL Cluster might not work. The default storage configuration is also not redundant. You can use software-based RAID to improve redundancy, but this implies a further performance hit.

15.1.3 Deploying a MySQL Database Using EC2

Because you cannot guarantee the uptime and availability of your EC2 instances, when deploying MySQL within the EC2 environment, use an approach that enables you to easily distribute work among your EC2 instances. There are a number of ways of doing this. Using sharding techniques, where you split the application across multiple servers dedicating specific blocks of your dataset and users to different servers is an effective way of doing this. As a general rule, it is easier to create more EC2 instances to support more users than to upgrade the instance to a larger machine.

The EC2 architecture works best when you treat the EC2 instances as temporary, cache-based solutions, rather than as a long-term, high availability solution. In addition to using multiple machines, take advantage of other services, such as `memcached` to provide additional caching for your application to help reduce the load on the MySQL server so that it can concentrate on writes. On the large and extra large instances within EC2, the RAM available can provide a large memory cache for data.

Most types of scale-out topology that you would use with your own hardware can be used and applied within the EC2 environment. However, use the limitations and advice already given to ensure that any potential failures do not lose you any data. Also, because the relative power of each EC2 instance is so low, be prepared to alter your application to use sharding and add further EC2 instances to improve the performance of your application.

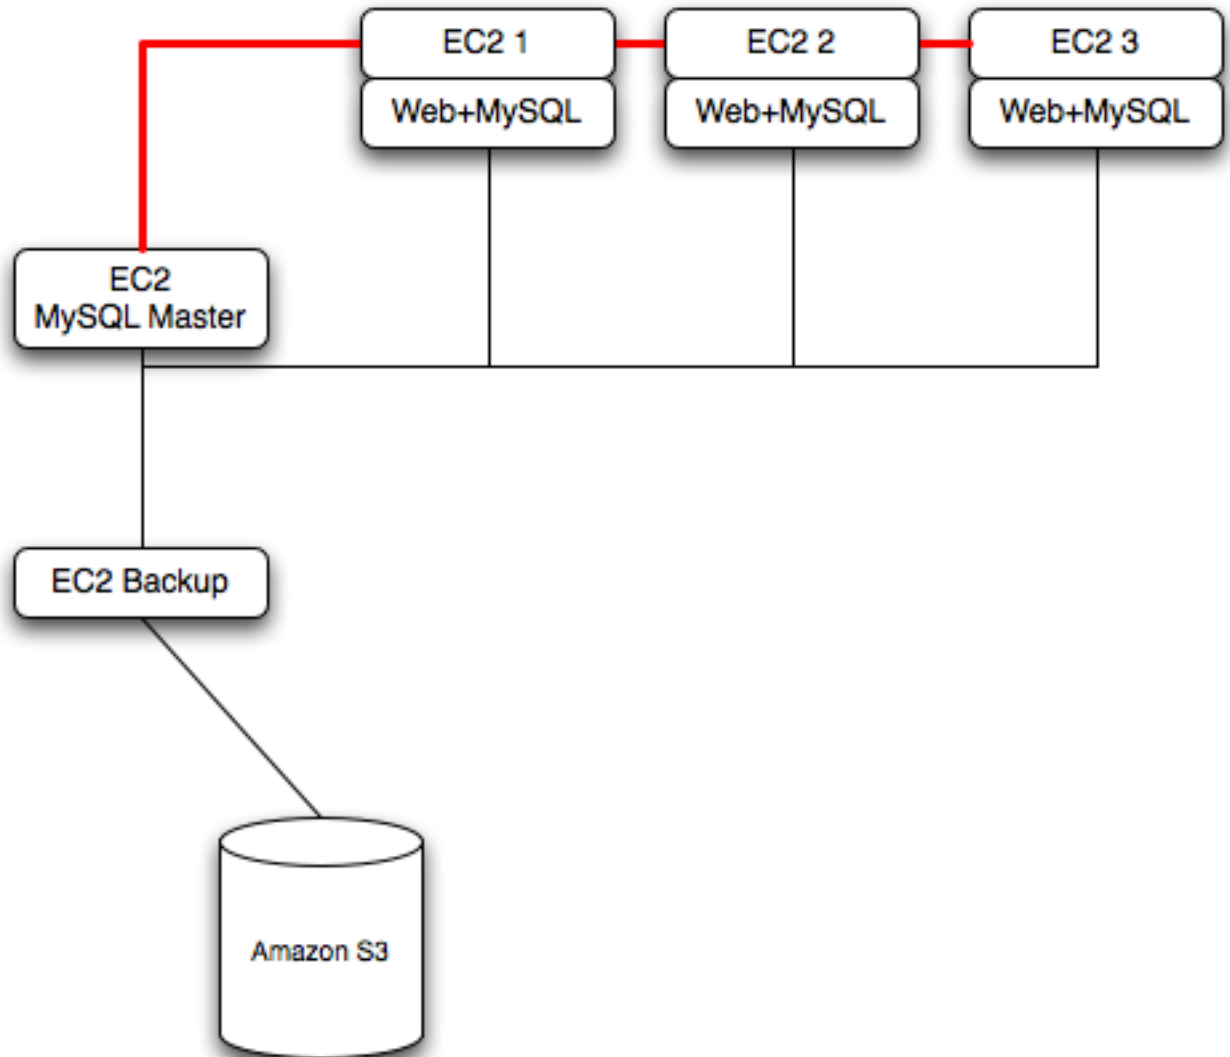
For example, take the typical scale-out environment shown following, where a single master replicates to one or more slaves (three in this example), with a web server running on each replication slave.


You can reproduce this structure completely within the EC2 environment, using an EC2 instance for the master, and one instance for each of the web and MySQL slave servers.

Note

Within the EC2 environment, internal (private) IP addresses used by the EC2 instances are constant. Always use these internal addresses and names when communicating between instances. Only use public IP addresses when

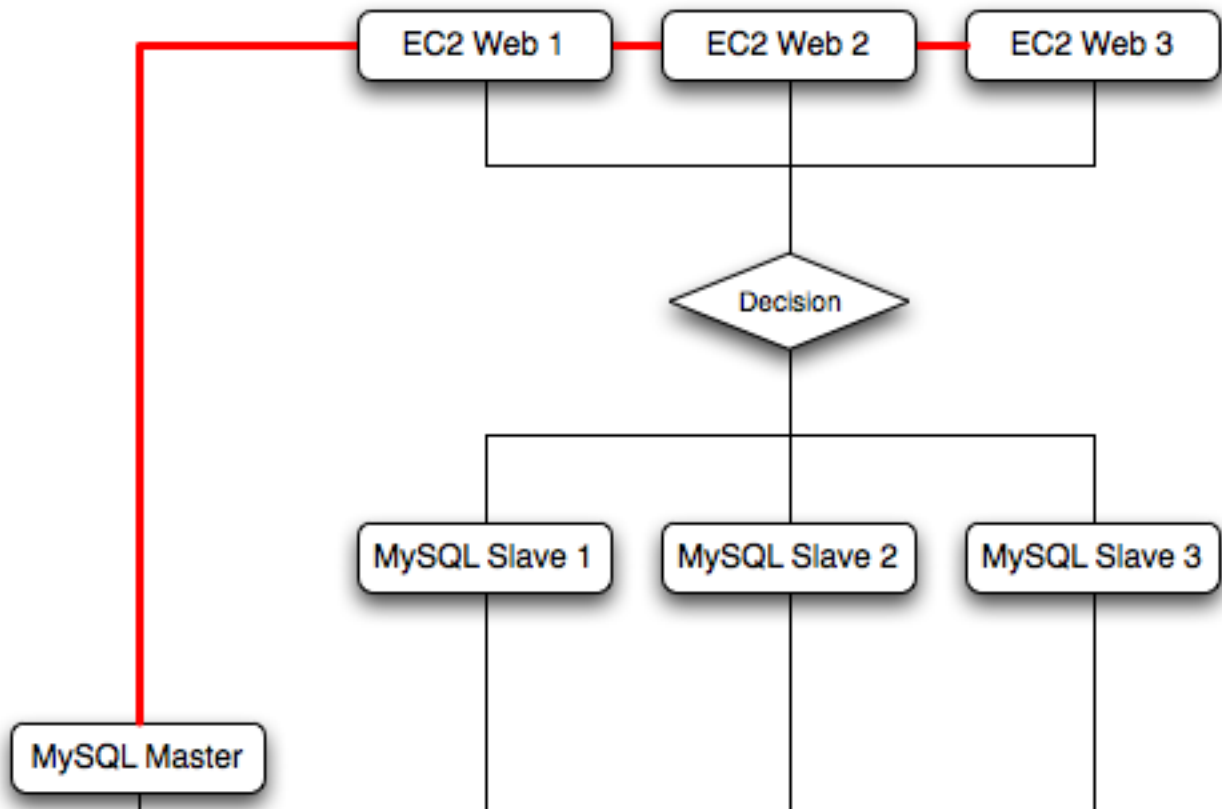
> communicating with the outside world - for example, when publicizing your
> application.

To ensure reliability of your database, add at least one replication slave dedicated to providing an active
backup and storage to the Amazon S3 facility. You can see an example of this in the following topology.


Using `memcached` within your EC2 instances should provide better performance. The large and extra
large instances have a significant amount of RAM. To use `memcached` in your application, when loading
information from the database, first check whether the item exists in the cache. If the data you are looking
for exists in the cache, use it. If not, reload the data from the database and populate the cache.

Sharding divides up data in your entire database by allocating individual machines or machine groups to
provide a unique set of data according to an appropriate group. For example, you might put all users with a
surname ending in the letters A-D onto a single server. When a user connects to the application and their
surname is known, queries can be redirected to the appropriate MySQL server.

When using sharding with EC2, separate the web server and MySQL server into separate EC2 instances,
and then apply the sharding decision logic into your application. Once you know which MySQL server you

should be using for accessing the data you then distribute queries to the appropriate server. You can see a sample of this in the following illustration.


Warning

With sharding and EC2, be careful that the potential for failure of an instance does not affect your application. If the EC2 instance that provides the MySQL server for a particular shard fails, then all of the data on that shard becomes unavailable.

15.2 Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, such as Chapter 16, *Replication*.

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at `/scratchpool`:

```
Filesystem            size   used  avail capacity  Mounted on
/dev/dsk/c0d0s0       4.6G   3.7G   886M    82%    /
/devices               0K     0K     0K     0%    /devices
```

```
ctfs                     0K     0K     0K    0%    /system/contract
proc                     0K     0K     0K    0%    /proc
mnttab                   0K     0K     0K    0%    /etc/mnttab
swap                    1.4G   892K   1.4G    1%    /etc/svc/volatile
objfs                    0K     0K     0K    0%    /system/object
/usr/lib/libc/libc_hwcap1.so.1
                        4.6G   3.7G   886M   82%    /lib/libc.so.1
fd                       0K     0K     0K    0%    /dev/fd
swap                    1.4G    40K   1.4G    1%    /tmp
swap                    1.4G    28K   1.4G    1%    /var/run
/dev/dsk/c0d0s7          26G   913M    25G    4%    /export/home
scratchpool              16G    24K    16G    1%    /scratchpool
```

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```
total 17
drwxr-xr-x  31 root     bin           50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root     bin            5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root     sys           16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000     1000          40 Nov  6 19:16 emacs-22.1/
```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1      0     -   24.5K  -
scratchpool@snap2      0     -   24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

15.2.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to slavepool. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x   6 root      root             7 Nov  8 09:13 ./
drwxr-xr-x  29 root      root            34 Nov  9 07:06 ../
drwxr-xr-x  31 root      bin             50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root      bin              5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root      sys             16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000      1000            40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

15.2.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send`/ `zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals.

15.2.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.

2. Set the slave file system to be read/write:

    ```
    root-shell> zfs set readonly=off slavepool
    ```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

    ```
    InnoDB: The log sequence number in ibdata files does not match
    InnoDB: the log sequence number in the ib_logfiles!
    081109 15:59:59  InnoDB: Database was not shut down normally!
    InnoDB: Starting crash recovery.
    InnoDB: Reading tablespace information from the .ibd files...
    InnoDB: Restoring possible half-written data pages from the doublewrite
    InnoDB: buffer...
    081109 16:00:03  InnoDB: Started; log sequence number 0 1142807951
    081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
    Version: '5.0.67'  socket: '/tmp/mysql.sock'  port: 3306  MySQL Community Server (GPL)
    ```

Use `InnoDB` tables and a regular synchronization schedule to reduce the risk for significant data loss. On MyISAM tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

15.3 Using MySQL with `memcached`

`memcached` is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the `memcached` command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see Section 15.3.2, "Using `memcached`"

Benefits of using `memcached` include:

- Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.

- Because the "value" portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.

- If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any `memcached` server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information is not in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see Figure 15.2, "`memcached` Architecture Overview".

Figure 15.2 `memcached` Architecture Overview
In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same `memcached` server is selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible

from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database.

15.3.1 Installing `memcached`

You can build and install `memcached` from the source code directly, or you can use an existing operating system package or installation.

Installing `memcached` from a Binary Distribution

To install `memcached` on a Red Hat, or Fedora host, use `yum`:

```
root-shell> yum install memcached
```

> **Note**
>
> On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
root-shell> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
root-shell> emerge install memcached
```

Building `memcached` from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface. For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from `libevent` web page.

You can obtain the source for `memcached` from `memcached` Web site.

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

   ```
   shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
   ```

2. Change to the `memcached-1.2.5 directory`:

   ```
   shell> cd memcached-1.2.5
   ```

3. Run `configure`

   ```
   shell> ./configure
   ```

   Some additional options you might specify to the `configure`:

- `--prefix`

  To specify a different installation directory, use the `--prefix` option:

  ```
  shell> ./configure --prefix=/opt
  ```

  The default is to use the `/usr/local` directory.

- `--with-libevent`

  If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

  To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

  To enable multi-threading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see Section 15.3.2.8, "`memcached` Thread Support".

- `--enable-dtrace`

  `memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see Section 15.3.2.6, "Using `memcached` and DTrace".

4. Run `make` to build `memcached`:

   ```
   shell> make
   ```

5. Run `make install` to install `memcached`:

   ```
   shell> make install
   ```

15.3.2 Using `memcached`

To start using `memcached`, start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

> **Note**
>
> You do not need to be a privileged user (`root`) to run `memcached` except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB

- Listens for connections on all network interfaces, using port 11211

- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

15.3.2.1 `memcached` Command-Line Options

`memcached` supports the following options:

- `-u user`

  If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

  ```
  shell> memcached -u memcache
  ```

- `-m memory`

  Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

  To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

  > **Warning**
  >
  > Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.
  >
  > You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:
  >
  > ```
  > shell> vmstat
  > kthr      memory            page            disk          faults      cpu
  > r b w   swap  free  re  mf pi po fr de sr s1 s2 -- --   in   sy   cs us sy id
  > 0 0 0 5170504 3450392 2   7  2  0  0  0  4  0  0  0  0  296   54  199  0  0 100
  > ```

  For example, to allocate 3GB of RAM:

  ```
  shell> memcached -m 3072
  ```

  On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

> **Note**
>
> On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- `-l interface`

  Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

  ```
  shell> memcached -l 192.168.0.110
  ```

  Support for IPv6 address support was added in `memcached` 1.2.5.

- `-p port`

  Specify the TCP port to use for connections. Default is 18080.

  ```
  shell> memcached -p 18080
  ```

- `-U port`

  Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

  ```
  shell> memcached -U 18080
  ```

- `-s socket`

  Specify a Unix socket to listen on.

  If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local Unix socket using the `-s` option:

  ```
  shell> memcached -s /tmp/memcached
  ```

  Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

  Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

  Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

```
shell> memcached -c 2048
```

Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

  Specify the number of threads to use when processing incoming requests.

  By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

```
shell> memcached -t 8
```

- `-d`

  Run `memcached` as a daemon (background) process:

```
shell> memcached -d
```

- `-r`

  Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

  Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- `-k`

  Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

  > **Note**
  >
  > There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- `-v`

  Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

  Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-vvv`

  Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- `-h`

  Print the help message and exit.

- `-i`

  Print the `memcached` and `libevent` license.

- `-I mem`

  Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

  ```
  shell> memcached -I 32m
  ```

  The maximum object size you can specify is 128MB, the default remains at 1MB.

  This option was added in 1.4.2.

- `-b`

  Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- `-P pidfile`

  Save the process ID of the `memcached` instance into `file`.

- `-f`

  Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

  To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see Section 15.3.2.9, "`memcached` Logs".

- `-n bytes`

  The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

  On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- `-C`

  Disable the use of compare and swap (CAS) operations.

  This option was added in `memcached` 1.3.x.

- `-D char`

Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see Section 15.3.4, "Getting `memcached` Statistics"). The default is the colon (`:`). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

This option was added in `memcached` 1.3.x.

- `-R num`

Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

This option was added in `memcached` 1.4.0.

15.3.2.2 `memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying `memcached` within your system, keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.

- There is no security built into the `memcached` protocol. At a minimum, make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the `memcached` servers that is being stored is any sensitive, then encrypt the information before storing it in `memcached`.

- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.

- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.

- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.

- Try to use at least two `memcached` instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many `memcached` nodes as possible. When adding and removing `memcached` instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see Section 15.3.2.5, "`memcached` Hashing/Distribution Types".

15.3.2.3 Using Namespaces

The `memcached` cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

Note

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

15.3.2.4 Data Expiry

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key/value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see Section 15.3.4, "Getting `memcached` Statistics".

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

15.3.2.5 `memcached` Hashing/Distribution Types

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within `memcache` clients uses a simple modulus calculation on the value against the number of configured `memcached` servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 (`7009 % 3 = 1`), and store or retrieve the key and value with that server.

> **Note**
>
> This selection and hashing process is handled automatically by the `memcached` client you are using; you need only provide the list of `memcached` servers to use.

You can see a graphical representation of this below in Figure 15.3, "`memcached` Hash Selection".

Figure 15.3 `memcached` Hash Selection
The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.

- Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).

- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.

- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.

- Using client-side hashing simplifies the distribution of data over each `memcached` server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.

> **Note**
>
> One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the `memcached` servers, and the servers must be available. If you try to perform an operation on a key when:

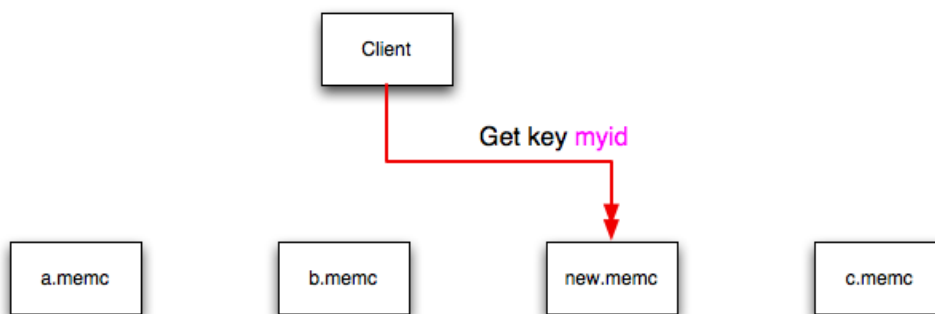
- A new `memcached` instance has been added to the list of available instances

- A `memcached` instance has been removed from the list of available instances

- The order of the `memcached` instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new `memcached` instance is added into the list of servers, as `new.memc` is in the example below, then a GET operation using the same key, `myid`, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server `c.memc` where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another `memcached` instance.

Figure 15.4 `memcached` Hash Selection with New `memcached` instance


This means that servers `c.memc` and `new.memc` both contain the information for key `myid`, but the information stored against the key in eachs server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the `memcached` instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured `memcached` instances as each instance is identified as being available. For example, removing a `memcached` instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

15.3.2.6 Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the DTrace User Guide.

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, build from source and use the `--enable-dtrace` option. For more information, see Section 15.3.1, "Installing `memcached`".

The probes supported by `memcached` are:

- `conn-allocate(connid)`

  Fired when a connection object is allocated from the connection pool.

  - `connid`: The connection ID.

- `conn-release(connid)`

  Fired when a connection object is released back to the connection pool.

  Arguments:

- `connid`: The connection ID.

- `conn-create(ptr)`

  Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

  Arguments:

  - `ptr`: A pointer to the connection. object

- `conn-destroy(ptr)`

  Fired when a connection object is being destroyed.

  Arguments:

  - `ptr`: A pointer to the connection object.

- `conn-dispatch(connid, threadid)`

  Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

  Arguments:

  - `connid`: The connection ID.

  - `threadid`: The thread ID.

- `slabs-allocate(size, slabclass, slabsize, ptr)`

  Allocate memory from the slab allocator.

  Arguments:

  - `size`: The requested size.

  - `slabclass`: The allocation is fulfilled in this class.

  - `slabsize`: The size of each item in this class.

  - `ptr`: A pointer to allocated memory.

- `slabs-allocate-failed(size, slabclass)`

  Failed to allocate memory (out of memory).

  Arguments:

  - `size`: The requested size.

  - `slabclass`: The class that failed to fulfill the request.

- `slabs-slabclass-allocate(slabclass)`

  Fired when a slab class needs more space.

Arguments:

- `slabclass`: The class that needs more memory.

- `slabs-slabclass-allocate-failed(slabclass)`

  Failed to allocate memory (out of memory).

  Arguments:

  - `slabclass`: The class that failed to grab more memory.

- `slabs-free(size, slabclass, ptr)`

  Release memory.

  Arguments:

  - `size`: The amount of memory to release, in bytes.

  - `slabclass`: The class the memory belongs to.

  - `ptr`: A pointer to the memory to release.

- `assoc-find(key, depth)`

  Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.

  Arguments:

  - `key`: The key searched for.

  - `depth`: The depth in the list of hash table.

- `assoc-insert(key, nokeys)`

  Fired when a new item has been inserted.

  Arguments:

  - `key`: The key just inserted.

  - `nokeys`: The total number of keys currently being stored, including the key for which insert was called.

- `assoc-delete(key, nokeys)`

  Fired when a new item has been removed.

  Arguments:

  - `key`: The key just deleted.

  - `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.

- `item-link(key, size)`

Fired when an item is being linked in the cache.

Arguments:

- `key`: The items key.

- `size`: The size of the data.

- `item-unlink(key, size)`

  Fired when an item is being deleted.

  Arguments:

  - `key`: The items key.

  - `size`: The size of the data.

- `item-remove(key, size)`

  Fired when the refcount for an item is reduced.

  Arguments:

  - `key`: The item's key.

  - `size`: The size of the data.

- `item-update(key, size)`

  Fired when the "last referenced" time is updated.

  Arguments:

  - `key`: The item's key.

  - `size`: The size of the data.

- `item-replace(oldkey, oldsize, newkey, newsize)`

  Fired when an item is being replaced with another item.

  Arguments:

  - `oldkey`: The key of the item to replace.

  - `oldsize`: The size of the old item.

  - `newkey`: The key of the new item.

  - `newsize`: The size of the new item.

- `process-command-start(connid, request, size)`

  Fired when the processing of a command starts.

  Arguments:

- `connid`: The connection ID.

- `request`: The incoming request.

- `size`: The size of the request.

- `process-command-end(connid, response, size)`

  Fired when the processing of a command is done.

  Arguments:

  - `connid`: The connection ID.

  - `response`: The response to send back to the client.

  - `size`: The size of the response.

- `command-get(connid, key, size)`

  Fired for a `get` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The size of the key's data (or -1 if not found).

- `command-gets(connid, key, size, casid)`

  Fired for a `gets` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The size of the key's data (or -1 if not found).

  - `casid`: The casid for the item.

- `command-add(connid, key, size)`

  Fired for a `add` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The new size of the key's data (or -1 if not found).

- `command-set(connid, key, size)`

Fired for a `set` command.

Arguments:

- `connid`: The connection ID.

- `key`: The requested key.

- `size`: The new size of the key's data (or -1 if not found).

- `command-replace(connid, key, size)`

  Fired for a `replace` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The new size of the key's data (or -1 if not found).

- `command-prepend(connid, key, size)`

  Fired for a `prepend` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The new size of the key's data (or -1 if not found).

- `command-append(connid, key, size)`

  Fired for a `append` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The new size of the key's data (or -1 if not found).

- `command-cas(connid, key, size, casid)`

  Fired for a `cas` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The size of the key's data (or -1 if not found).

- `casid`: The cas ID requested.

- `command-incr(connid, key, val)`

  Fired for `incr` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `val`: The new value.

- `command-decr(connid, key, val)`

  Fired for `decr` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `val`: The new value.

- `command-delete(connid, key, exptime)`

  Fired for a `delete` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `exptime`: The expiry time.

15.3.2.7 Memory Allocation within `memcached`

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

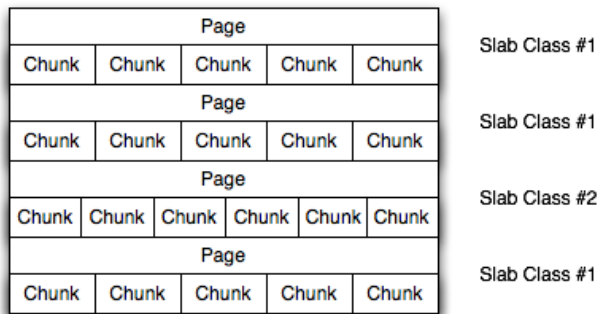
With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see Figure 15.5, "Memory Allocation in `memcached`".

Figure 15.5 Memory Allocation in `memcached`


The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for 104*1.25, or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see Section 15.3.4.2, "`memcached` Slabs Statistics".

If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

15.3.2.8 `memcached` Thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.

- Each thread uses its own instance of the `libevent` to help improve performance.

- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.

- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

15.3.2.9 `memcached` Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by `memcached` includes details of the operations being performed.

Without the verbose options, `memcached` normally produces no output during normal operating.

- **Output when using `-v`**

  The lowest verbosity level shows you:

  - Errors and warnings

  - Transient errors

  - Protocol and socket errors, including exhausting available connections

  - Each registered client connection, including the socket descriptor number and the protocol used.

    For example:

    ```
    32: Client using the ascii protocol
    33: Client using the ascii protocol
    ```

    The socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

  Examples of the error messages output at this level include:

  ```
  <%d send buffer was %d, now %d
  Can't listen for events on fd %d
  Can't read from libevent pipe
  Catastrophic: event fd doesn't match conn fd!
  Couldn't build response
  Couldn't realloc input buffer
  Couldn't update event
  Failed to build UDP headers
  Failed to read, and not due to blocking
  Too many open connections
  Unexpected state %d
  ```

- **Output when using `-vv`**

When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operatings and details.

During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```
shell> memcached -vv
slab class   1: chunk size      80 perslab 13107
slab class   2: chunk size     104 perslab 10082
slab class   3: chunk size     136 perslab  7710
slab class   4: chunk size     176 perslab  5957
slab class   5: chunk size     224 perslab  4681
slab class   6: chunk size     280 perslab  3744
slab class   7: chunk size     352 perslab  2978
slab class   8: chunk size     440 perslab  2383
slab class   9: chunk size     552 perslab  1899
slab class  10: chunk size     696 perslab  1506
slab class  11: chunk size     872 perslab  1202
slab class  12: chunk size    1096 perslab   956
slab class  13: chunk size    1376 perslab   762
slab class  14: chunk size    1720 perslab   609
slab class  15: chunk size    2152 perslab   487
slab class  16: chunk size    2696 perslab   388
slab class  17: chunk size    3376 perslab   310
slab class  18: chunk size    4224 perslab   248
slab class  19: chunk size    5280 perslab   198
slab class  20: chunk size    6600 perslab   158
slab class  21: chunk size    8256 perslab   127
slab class  22: chunk size   10320 perslab   101
slab class  23: chunk size   12904 perslab    81
slab class  24: chunk size   16136 perslab    64
slab class  25: chunk size   20176 perslab    51
slab class  26: chunk size   25224 perslab    41
slab class  27: chunk size   31536 perslab    33
slab class  28: chunk size   39424 perslab    26
slab class  29: chunk size   49280 perslab    21
slab class  30: chunk size   61600 perslab    17
slab class  31: chunk size   77000 perslab    13
slab class  32: chunk size   96256 perslab    10
slab class  33: chunk size 120320 perslab     8
slab class  34: chunk size 150400 perslab     6
slab class  35: chunk size 188000 perslab     5
slab class  36: chunk size 235000 perslab     4
slab class  37: chunk size 293752 perslab     3
slab class  38: chunk size 367192 perslab     2
slab class  39: chunk size 458992 perslab     2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```
shell> memcached -f 4 -m 1g -vv
slab class   1: chunk size     80 perslab 13107
slab class   2: chunk size    320 perslab  3276
slab class   3: chunk size   1280 perslab   819
slab class   4: chunk size   5120 perslab   204
slab class   5: chunk size  20480 perslab    51
slab class   6: chunk size  81920 perslab    12
slab class   7: chunk size 327680 perslab     3
...
```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```
32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key1 1 36

>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the `memcached` server and > for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

  This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if `memcached` is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

  ```
  <32 new auto-negotiating client connection
  32: going from conn_new_cmd to conn_waiting
  32: going from conn_waiting to conn_read
  32: going from conn_read to conn_parse_cmd
  32: Client using the ascii protocol
  <32 set my_key 0 0 10
  32: going from conn_parse_cmd to conn_nread
  > NOT FOUND my_key
  >32 STORED
  32: going from conn_nread to conn_write
  32: going from conn_write to conn_new_cmd
  32: going from conn_new_cmd to conn_waiting
  32: going from conn_waiting to conn_read
  32: going from conn_read to conn_closing
  <32 connection closed.
  ```

  All of the verbosity levels in `memcached` are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using `memcached`. Therefore, use in production or deployment environments is not recommended.

15.3.3 Developing a `memcached` Application

A number of language interfaces let applications store and retrieve information with `memcached` servers. You can write `memcached` applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

15.3.3.1 Basic `memcached` Operations

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- `get(key)`: Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns `NULL`, `nil`, `undefined`, or the closest equivalent in the corresponding language, if the specified key does not exist.

- `set(key, value [, expiry])`: Sets the item associated with a key in the cache to the specified value. This either updates an existing item if the key already exists, or adds a new key/value pair if the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry

time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days (30*24*60*60), or an absolute time (epoch) if larger than this value.

- `add(key, value [, expiry])`: Adds the key and associated value to the cache, if the specified key does not already exist.

- `replace(key, value [, expiry])`: Replaces the item associated with the specified `key`, only if the key already exists. The new value is given by the `value` parameter.

- `delete(key [, time])`: Deletes the `key` and its associated item from the cache. If you supply a `time`, then adding another item with the specified `key` is blocked for the specified period.

- `incr(key , value)`: Increments the item associated with the `key` by the specified `value`.

- `decr(key , value)`: Decrements the item associated with the `key` by the specified `value`.

- `flush_all`: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use `memcached` to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

15.3.3.2 Using `memcached` as a MySQL Caching Layer

When using `memcached` to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the `InnoDB` buffer pool and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

> **Caution**
>
> Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a `memcached` instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use IPTables or similar techniques to restrict access to the `memcached` ports to a select set of hosts.

You can introduce `memcached` to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first

to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

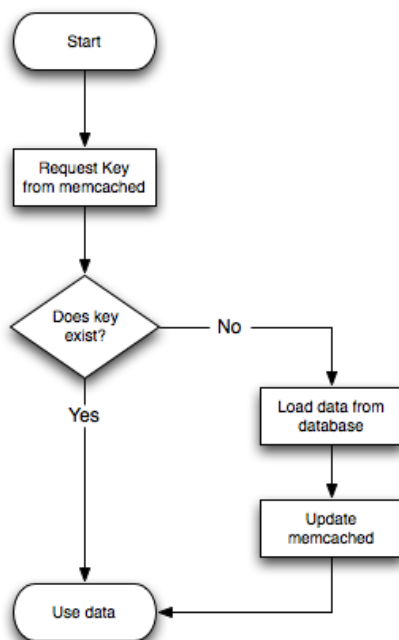
The general sequence for using `memcached` in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.

2. If the item exists, use the item data.

3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see Figure 15.6, "Typical `memcached` Application Flowchart".

Figure 15.6 Typical `memcached` Application Flowchart


Adapting Database Best Practices to `memcached` Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a primary key. Because of the uniqueness requirements for `memcached` keys, make sure your database schema makes appropriate use of primary keys and unique constraints.

If you combine multiple column values into a single `memcached` item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to `memcached` lookups are those with a single `WHERE` clause, using an `=` or `IN` operator. For complicated `WHERE` clauses, or those using operators such as `<`, `>`, `BETWEEN`, or `LIKE`, `memcached` does not provide a simple or efficient way to scan through or filter the keys or associated values, so typically you perform those operations as SQL queries on the underlying database.

15.3.3.3 Using `libmemcached` with C and C++

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides functions and operational systems not always exposed in interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run `configure`, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get`, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main `memcached_st` structure, or separately populate a list of servers, and then add this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to `localhost` is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
  memcached_server_st *servers = NULL;
  memcached_st *memc;
  memcached_return rc;
  char *key= "keystring";
  char *value= "keyvalue";

  memcached_server_st *memcached_servers_parse (char *server_strings);
  memc= memcached_create(NULL);

  servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
  rc= memcached_server_push(memc, servers);

  if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr,"Added server successfully\n");
  else
    fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

  rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

  if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr,"Key stored successfully\n");
  else
```

```
    fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));

  return 0;
}
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
Added server successfully
Key stored successfully
```

`libmemcached` Base Functions

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

`libmemcached` Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```
memcached_return
   memcached_server_add (memcached_st *ptr,
```

```
                        char *hostname,
                        unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```
memcached_return
   memcached_server_add_unix_socket (memcached_st *ptr,
                                     char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *
   memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return
   memcached_server_push (memcached_st *ptr,
                          memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *
   memcached_server_list_append (memcached_server_st *ptr,
                                 char *hostname,
                                 unsigned int port,
                                 memcached_return *error);
```

Adds a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

`libmemcached` Set Functions

The set-related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (`add`, `replace`, `prepend`, `append`). For example, the function definition for `memcached_set()` is:

```
memcached_return
   memcached_set (memcached_st *ptr,
                  const char *key,
                  size_t key_length,
                  const char *value,
                  size_t value_length,
                  time_t expiration,
                  uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see Controlling `libmemcached` Behaviors.

This table outlines the remainder of the set-related `libmemcached` functions and the equivalent core functions supported by the `memcached` protocol.

`libmemcached` Function	Equivalent Core Function
`memcached_set(memc, key, key_length, value, value_length, expiration, flags)`	Generic `set()` operation.
`memcached_add(memc, key, key_length, value, value_length, expiration, flags)`	Generic `add()` function.
`memcached_replace(memc, key, key_length, value, value_length, expiration, flags)`	Generic `replace()`.
`memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)`	Prepends the specified `value` before the current value of the specified `key`.
`memcached_append(memc, key, key_length, value, value_length, expiration, flags)`	Appends the specified `value` after the current value of the specified `key`.
`memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)`	Overwrites the data for a given key as long as the corresponding `cas` value is still the same within the server.
`memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)`	Similar to the generic `set()`, but has the option of an additional master key that can be used to identify an individual server.
`memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)`	Similar to the generic `add()`, but has the option of an additional master key that can be used to identify an individual server.
`memcached_replace_by_key(memc, master_key, master_key_length, key,`	Similar to the generic `replace()`, but has the option of an additional master key that can be used to identify an individual server.

`libmemcached` Function	Equivalent Core Function
`key_length, value, value_length, expiration, flags)`	
`memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)`	Similar to the `memcached_prepend()`, but has the option of an additional master key that can be used to identify an individual server.
`memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)`	Similar to the `memcached_append()`, but has the option of an additional master key that can be used to identify an individual server.
`memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)`	Similar to the `memcached_cas()`, but has the option of an additional master key that can be used to identify an individual server.

The `by_key` methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
    memcached_set_by_key(memcached_st *ptr,
                         const char *master_key,
                         size_t master_key_length,
                         const char *key,
                         size_t key_length,
                         const char *value,
                         size_t value_length,
                         time_t expiration,
                         uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

`libmemcached` Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```
char *memcached_get (memcached_st *ptr,
                     const char *key, size_t key_length,
                     size_t *value_length,
                     uint32_t *flags,
                     memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```
memcached_return
    memcached_mget (memcached_st *ptr,
                    char **keys, size_t *key_length,
                    unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                       const char *key, size_t *key_length,
                       size_t *value_length,
                       uint32_t *flags,
                       memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <sstring.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
  memcached_server_st *servers = NULL;
  memcached_st *memc;
  memcached_return rc;
  char *keys[]= {"huey", "dewey", "louie"};
  size_t key_length[3];
  char *values[]= {"red", "blue", "green"};
  size_t value_length[3];
  unsigned int x;
  uint32_t flags;

  char return_key[MEMCACHED_MAX_KEY];
  size_t return_key_length;
  char *return_value;
  size_t return_value_length;

  memc= memcached_create(NULL);

  servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
  rc= memcached_server_push(memc, servers);

  if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr,"Added server successfully\n");
  else
    fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

  for(x= 0; x < 3; x++)
    {
      key_length[x] = strlen(keys[x]);
      value_length[x] = strlen(values[x]);

      rc= memcached_set(memc, keys[x], key_length[x], values[x],
                        value_length[x], (time_t)0, (uint32_t)0);
      if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Key %s stored successfully\n",keys[x]);
      else
        fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));
    }

  rc= memcached_mget(memc, keys, key_length, 3);
```

```
   if (rc == MEMCACHED_SUCCESS)
     {
       while ((return_value= memcached_fetch(memc, return_key, &return_key_length,
                                     &return_value_length, &flags, &rc)) != NULL)
        {
          if (rc == MEMCACHED_SUCCESS)
            {
               fprintf(stderr,"Key %s returned %s\n",return_key, return_value);
            }
        }
     }

  return 0;
}
```

Running the above application produces the following output:

```
shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green
```

Controlling `libmemcached` Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```
memcached_return
    memcached_behavior_set (memcached_st *ptr,
                            memcached_behavior flag,
                            uint64_t data);
```

To get the current behavior setting:

```
uint64_t
    memcached_behavior_get (memcached_st *ptr,
                            memcached_behavior flag);
```

The following table describes `libmemcached` behavior flags.

Behavior	Description
MEMCACHED_BEHAVIOR_NO_BLOCK	Caused `libmemcached` to use asynchronous I/O.
MEMCACHED_BEHAVIOR_TCP_NODELAY	Turns on no-delay for network sockets.
MEMCACHED_BEHAVIOR_HASH	Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include MEMCACHED_HASH_DEFAULT, MEMCACHED_HASH_MD5, MEMCACHED_HASH_CRC, MEMCACHED_HASH_FNV1_64, MEMCACHED_HASH_FNV1A_64, MEMCACHED_HASH_FNV1_32, and MEMCACHED_HASH_FNV1A_32.
MEMCACHED_BEHAVIOR_DISTRIBUTION	Changes the method of selecting the server used to store a given value. The default method

Behavior	Description
	is `MEMCACHED_DISTRIBUTION_MODULA`. You can enable consistent hashing by setting `MEMCACHED_DISTRIBUTION_CONSISTENT`. `MEMCACHED_DISTRIBUTION_CONSISTENT` is an alias for the value `MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA`.
`MEMCACHED_BEHAVIOR_CACHE_LOOKUPS`	Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.
`MEMCACHED_BEHAVIOR_SUPPORT_CAS`	Support CAS operations. By default, this is disabled because it imposes a performance penalty.
`MEMCACHED_BEHAVIOR_KETAMA`	Sets the default distribution to `MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA` and the hash to `MEMCACHED_HASH_MD5`.
`MEMCACHED_BEHAVIOR_POLL_TIMEOUT`	Modify the timeout value used by `poll()`. Supply a `signed int` pointer for the timeout value.
`MEMCACHED_BEHAVIOR_BUFFER_REQUESTS`	Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.
`MEMCACHED_BEHAVIOR_VERIFY_KEY`	Forces `libmemcached` to verify that a specified key is valid.
`MEMCACHED_BEHAVIOR_SORT_HOSTS`	If set, hosts added to the list of configured hosts for a `memcached_st` structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.
`MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT`	In nonblocking mode this changes the value of the timeout during socket connection.

`libmemcached` Command-Line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command-line utilities that can be useful when working with and debugging `memcached` applications.

All of the command-line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat`: Display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- `memcp`: Copy the contents of a file into the cache, using the file name as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- `memrm`: Remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- `memslap`: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
 Took 13.571 seconds to read data
```

- `memflush`: Flush (empty) the contents of the `memcached` cache.

```
shell> memflush --servers=localhost
```

15.3.3.4 Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. Install the module using your operating system's package management system, or using `CPAN`:

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through the `Cache::Memcached` module, first create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
 ],
};
```

> **Note**
>
> When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.

- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.

- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.

- `readonly` or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured, you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

`Cache::Memcached` Function	Equivalent Generic Method
`get()`	Generic `get()`.
`get_multi(keys)`	Gets multiple `keys` from memcache using just one query. Returns a hash reference of key/value pairs.
`set()`	Generic `set()`.
`add()`	Generic `add()`.
`replace()`	Generic `replace()`.
`delete()`	Generic `delete()`.
`incr()`	Generic `incr()`.
`decr()`	Generic `decr()`.

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```perl
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server

my $cache = new Cache::Memcached {
    'servers' => [
                  'localhost:11211',
                  ],
    };

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores

my $filmname = shift or die "Must specify the film name\n";
my $filmkey = $filmname;
$filmkey =~ s/ /_/;

# Load the data from the cache

my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database
```

```
if (!defined($filmdata))
{
    $filmdata = load_filmdata($filmname);

    if (defined($filmdata))
    {

# Set the data into the cache, using the key

 if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
 }
    }
    else
    {
      die "Couldn't find $filmname\n";
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmname) = @_;

    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";

    $dbh = DBI->connect($dsn, 'sakila','password');

    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
                                                   $dbh->quote($filmname)));

    if (!defined($filmname))
    {
      return (undef);
    }

    $filmbase->{stars} =
 $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
                                  'from film_actor left join (actor) ' .
                                  'on (film_actor.actor_id = actor.actor_id) ' .
                                  ' where film_id=%s',
                                  $dbh->quote($filmbase->{film_id})));

    return($filmbase);
}
```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to `memcached`. When calling it for a film does not exist, you get this result:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached
```

When accessing a film that has already been added to the cache:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
```

15.3.3.5 Using MySQL and `memcached` with Python

The Python `memcache` module interfaces to `memcached` servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from Python Memcached.

To install, download the package and then run the Python installer:

```
python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```

Once installed, the `memcache` module provides a class-based interface to your `memcached` servers. When you store Python data structures as `memcached` items, they are automatically serialized (turned into string values) using the Python `cPickle` or `pickle` modules.

To create a new `memcache` interface, import the `memcache` module and create a new instance of the `memcache.Client` class. For example, if the `memcached` daemon is running on localhost using the default port:

```
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument is an array of strings containing the server and port number for each `memcached` instance to use. To enable debugging, set the optional `debug` parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is `crc32`. To change the function used, set the value of `memcache.serverHashFunction` to the alternate function to use. For example:

```
from zlib import adler32
memcache.serverHashFunction = adler32
```

Once you have defined the servers to use within the `memcache` instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

Python `memcache` Function	Equivalent Generic Function
`get()`	Generic `get()`.
`get_multi(keys)`	Gets multiple values from the supplied array of `keys`. Returns a hash reference of key/value pairs.
`set()`	Generic `set()`.
`set_multi(dict [, expiry [, key_prefix]])`	Sets multiple key/value pairs from the supplied `dict`.
`add()`	Generic `add()`.

Python `memcache` Function	Equivalent Generic Function
`replace()`	Generic `replace()`.
`prepend(key, value [, expiry])`	Prepends the supplied `value` to the value of the existing `key`.
`append(key, value [, expiry[)`	Appends the supplied `value` to the value of the existing `key`.
`delete()`	Generic `delete()`.
`delete_multi(keys [, expiry [, key_prefix]] )`	Deletes all the keys from the hash matching each string in the array `keys`.
`incr()`	Generic `incr()`.
`decr()`	Generic `decr()`.

Note

Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys `users:a` and `users:b` from the servers.

Here is an example showing the storage and retrieval of information to a `memcache` instance, loading the raw data from MySQL:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                            user = "sakila",
                            passwd = "password",
                            db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the `memcached` server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

Because the data is automatically serialized using `cPickle`/`pickle`, when you load the data back from `memcached`, you can use the object directly. In the example above, the information stored to `memcached` is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from `memcached` and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

15.3.3.6 Using MySQL and `memcached` with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP `memcache` extensions, build PHP using the `--enable-memcache` option to `configure` when building from source.

If you are installing on a Red Hat-based server, you can install the `php-pecl-memcache` RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian-based distributions, use the `php-memcache` package.

To set global runtime configuration options, specify the configuration option values within your `php.ini` file. The following table provides the name, default value, and a description for each global runtime configuration option.

Configuration option	Default	Description
`memcache.allow_failover`	1	Specifies whether another server in the list should be queried if the first server selected fails.
`memcache.max_failover_attempts`	20	Specifies the number of servers to try before returning a failure.
`memcache.chunk_size`	8192	Defines the size of network chunks used to exchange data with the `memcached` server.
`memcache.default_port`	11211	Defines the default port to use when communicating with the `memcached` servers.
`memcache.hash_strategy`	standard	Specifies which hash strategy to use. Set to `consistent` to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to `standard`, an older (modula) strategy is used that potentially uses different servers for storage.

Configuration option	Default	Description
`memcache.hash_function`	crc32	Specifies which function to use when mapping keys to servers. `crc32` uses the standard CRC32 hash. `fnv` uses the FNV-1a hashing algorithm.

To create a connection to a `memcached` server, create a new `Memcache` object and then specify the connection options. For example:

```
<?php

$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the memcache object using `addServer()`:

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                 [, int $weight [, int $timeout [, int $retry_interval
                 [, bool $status [, callback $failure_callback
                 ]]]]]]] )
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```
<?php

$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to `memcached` instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by `memcached`, as shown in this table:

PECL `memcache` Function	Generic Function
`get()`	Generic `get()`.
`set()`	Generic `set()`.
`add()`	Generic `add()`.
`replace()`	Generic `replace()`.

PECL `memcache` Function	Generic Function
`delete()`	Generic `delete()`.
`increment()`	Generic `incr()`.
`decrement()`	Generic `decr()`.

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```php
<?php

$memc = new Memcache;
$memc->addServer('localhost','11211');

if(empty($_POST['film'])) {
?>
  <html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
    <head>
      <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
      <title>Simple Memcache Lookup</title>
    </head>
    <body>
      <form method="post">
        <p><b>Film</b>: <input type="text" size="20" name="film"></p>
        <input type="submit">
      </form>
      <hr/>
<?php

} else {

    echo "Loading data...\n";

    $film   = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);

    if ($mfilms) {

        printf("<p>Film data for %s loaded from memcache</p>", $mfilms['title']);

        foreach (array_keys($mfilms) as $key) {
            printf("<p><b>%s</b>: %s</p>", $key, $mfilms[$key]);
        }

    } else {

        $mysqli = mysqli('localhost','sakila','password','sakila');

        if (mysqli_connect_error()) {
            sprintf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }

        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));

        $result = $mysqli->query($sql);

        if (!$result) {
            sprintf("Database error: (%d) %s", $mysqli->errno, $mysqli->error);
            exit;
        }
```

```
        $row = $result->fetch_assoc();

        $memc->set($row['title'], $row);

        printf("<p>Loaded (%s) from MySQL</p>", htmlspecialchars($row['title'], ENT_QUOTES, 'UTF-8');
    }
}
?>
  </body>
</html>
```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

15.3.3.7 Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The `Ruby-MemCache` client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from http://www.deveiate.org/projects/RMemCache.

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the `Ruby-MemCache` gem:

```
shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn]  y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...
```

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```
memc += ["192.168.0.101:11211"]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table:

Ruby `MemCache` Method	Equivalent `memcached` API Functions
`get()`	Generic `get()`.
`get_hash(keys)`	Get the values of multiple `keys`, returning the information as a hash of the keys and their values.
`set()`	Generic `set()`.
`set_many(pairs)`	Set the values of the keys and values in the hash `pairs`.
`add()`	Generic `add()`.
`replace()`	Generic `replace()`.
`delete()`	Generic `delete()`.
`incr()`	Generic `incr()`.
`decr()`	Generic `decr()`.

15.3.3.8 Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from https://github.com/gwhalin/Memcached-Java-Client/downloads. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally, you can configure the `memcached` interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```
public class MyClass {

    protected static MemCachedClient mcc = new MemCachedClient();

    static {

        String[] servers =
            {
                "localhost:11211",
            };

        Integer[] weights = { 1 };
```

```
    SockIOPool pool = SockIOPool.getInstance();

    pool.setServers( servers );
    pool.setWeights( weights );
```

In the above sample, the list of servers is configured by creating an array of the `memcached` instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your `memcached` instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use `pool.setHashingAlg()`:

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modula hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `libmemcached`.

The following table outlines the Java `com.danga.MemCached` methods and the equivalent generic methods in the `memcached` interface specification.

Java `com.danga.MemCached` Method	Equivalent Generic Method
`get()`	Generic `get()`.
`getMulti(keys)`	Get the values of multiple `keys`, returning the information as Hash map using `java.lang.String` for the keys and `java.lang.Object` for the corresponding values.
`set()`	Generic `set()`.
`add()`	Generic `add()`.
`replace()`	Generic `replace()`.
`delete()`	Generic `delete()`.
`incr()`	Generic `incr()`.
`decr()`	Generic `decr()`.

15.3.3.9 Using the `memcached` TCP Text Protocol

Communicating with a `memcached` server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.

When communicating with `memcached`, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.

- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r` `\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands**: `set`, `add`, `replace`, `append`, `prepend`, `cas`

  Storage commands to the server take the form:

  ```
  command key [flags] [exptime] length [noreply]
  ```

  Or when using compare and swap (cas):

  ```
  cas key [flags] [exptime] length [casunique] [noreply]
  ```

  Where:

  - `command`: The command name.

    - `set`: Store value against key

    - `add`: Store this value against key if the key does not already exist

    - `replace`: Store this value against key if the key already exists

    - `append`: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.

    - `prepend`: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.

    - `cas`: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.

  - `key`: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.

  - `flags`: The flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.

  - `exptime`: The expiry time, or zero for no expiry.

- `length`: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.

- `casunique`: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.

- `noreply`: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n
```

The return value from the server is one line, specifying the status or error information. For more information, see Table 15.3, "`memcached` Protocol Responses".

- **Retrieval commands**: `get`, `gets`

  Retrieval commands take the form:

  ```
  get key1 [key2 .... keyn]
  gets key1 [key2 ... keyn]
  ```

  You can supply multiple keys to the commands, with each requested key separated by whitespace.

  The server responds with an information line of the form:

  ```
  VALUE key flags bytes [casunique]
  ```

  Where:

  - `key`: The key name.

  - `flags`: The value of the flag integer supplied to the `memcached` server when the value was stored.

  - `bytes`: The size (excluding the terminating `\r\n` character sequence) of the stored value.

  - `casunique`: The unique 64-bit integer that identifies the item.

  The information line is immediately followed by the value data block. For example:

  ```
  get xyzkey\r\n
  VALUE xyzkey 0 6\r\n
  abcdef\r\n
  ```

  If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands**: `delete`

  Deletion commands take the form:

  ```
  delete key [time] [noreply]
  ```

  Where:

  - `key`: The key name.

- `time`: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

  If not supplied, the value is assumed to be zero (delete immediately).

- `noreply`: Tells the server not to reply to the command.

Responses to the command are either `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement**: `incr`, `decr`

  The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

  Increment and decrement commands take the form:

  ```
  incr key value [noreply]
  decr key value [noreply]
  ```

  Where:

  - `key`: The key name.

  - `value`: An integer to be used as the increment or decrement value.

  - `noreply`: Tells the server not to reply to the command.

  The response is:

  - `NOT_FOUND`: The specified key could not be located.

  - `value`: The new value associated with the specified key.

  Values are assumed to be unsigned. For `decr` operations, the value is never decremented below 0. For `incr` operations, the value wraps around the 64-bit maximum.

- **Statistics commands**: `stats`

  The `stats` command provides detailed statistical information about the current status of the `memcached` instance and the data it is storing.

  Statistics commands take the form:

  ```
  STAT [name] [value]
  ```

  Where:

  - `name`: The optional name of the statistics to return. If not specified, the general statistics are returned.

  - `value`: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, END.

For more information, see Section 15.3.4, "Getting `memcached` Statistics".

For reference, a list of the different commands supported and their formats is provided below.

Table 15.2 `memcached` Command Reference

Command	Command Formats
set	set key flags exptime length, set key flags exptime length noreply
add	add key flags exptime length, add key flags exptime length noreply
replace	replace key flags exptime length, replace key flags exptime length noreply
append	append key length, append key length noreply
prepend	prepend key length, prepend key length noreply
cas	cas key flags exptime length casunique, cas key flags exptime length casunique noreply
get	get key1 [key2 ... keyn]
gets	
delete	delete key, delete key noreply, delete key expiry, delete key expiry noreply
incr	incr key, incr key noreply, incr key value, incr key value noreply
decr	decr key, decr key noreply, decr key value, decr key value noreply
stat	stat, stat name, stat name value

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by \r\n:

Table 15.3 `memcached` Protocol Responses

String	Description
STORED	Value has successfully been stored.
NOT_STORED	The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as add and replace), or where the item has already been set to be deleted.
EXISTS	When using a cas command, the item you are trying to store already exists and has been modified since you last checked it.
NOT_FOUND	The item you are trying to store, update or delete does not exist or has already been deleted.
ERROR	You submitted a nonexistent command name.

String	Description
`CLIENT_ERROR errorstring`	There was an error in the input line, the detail is contained in `errorstring`.
`SERVER_ERROR errorstring`	There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.
`VALUE keys flags length`	The requested key has been found, and the stored `key`, `flags` and data block are returned, of the specified `length`.
`DELETED`	The requested key was deleted from the server.
`STAT name value`	A line of statistics data.
`END`	The end of the statistics data.

15.3.4 Getting `memcached` Statistics

The `memcached` system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the Section 15.3.4.2, "`memcached` Slabs Statistics" and Section 15.3.4.1, "`memcached` General Statistics" information. For more information, see Section 15.3.4.6, "Using `memcached-tool`".

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
```

```
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
$memc->set_servers(\@ARGV);

print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
    'hosts' => {
            'localhost:11211' => {
                        'misc' => {
                                'bytes' => '2421',
                                'curr_connections' => '3',
                                'connection_structures' => '56',
                                'pointer_size' => '32',
                                'time' => '1211440166',
                                'total_items' => '410956',
                                'cmd_set' => '588167',
                                'bytes_written' => '35715151',
                                'evictions' => '0',
                                'curr_items' => '31',
                                'pid' => '23599',
                                'limit_maxbytes' => '67108864',
                                'uptime' => '1254',
                                'rusage_user' => '9.857805',
                                'cmd_get' => '838451',
                                'rusage_system' => '34.096988',
                                'version' => '1.2.5',
                                'get_hits' => '581511',
                                'bytes_read' => '46665716',
                                'threads' => '1',
                                'total_connections' => '3104',
                                'get_misses' => '256940'
                            },
                        'sizes' => {
                                '128' => '16',
                                '64' => '15'
                            }
                        }
            },
    'self' => {},
    'total' => {
            'cmd_get' => 838451,
            'bytes' => 2421,
            'get_hits' => 581511,
            'connection_structures' => 56,
            'bytes_read' => 46665716,
            'total_items' => 410956,
            'total_connections' => 3104,
```

```
          'cmd_set' => 588167,
          'bytes_written' => 35715151,
          'curr_items' => 31,
          'get_misses' => 256940
        }
      };
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see Section 15.3.4.1, "`memcached` General Statistics".

- Slab statistics (`slabs`), see Section 15.3.4.2, "`memcached` Slabs Statistics".

- Item statistics (`items`), see Section 15.3.4.3, "`memcached` Item Statistics".

- Size statistics (`sizes`), see Section 15.3.4.4, "`memcached` Size Statistics".

- Detailed status (`detail`), see Section 15.3.4.5, "`memcached` Detail Statistics".

15.3.4.1 `memcached` General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u`: 32-bit unsigned integer

- `64u`: 64-bit unsigned integer

- `32u:32u`: Two 32-bit unsigned integers separated by a colon

- `String`: Character string

Statistic	Data type	Description	Version
`pid`	32u	Process ID of the `memcached` instance.	
`uptime`	32u	Uptime (in seconds) for this `memcached` instance.	
`time`	32u	Current time (as epoch).	
`version`	string	Version string of this instance.	
`pointer_size`	string	Size of pointers for this host specified in bits (32 or 64).	
`rusage_user`	32u:32u	Total user time for this instance (seconds:microseconds).	
`rusage_system`	32u:32u	Total system time for this instance (seconds:microseconds).	
`curr_items`	32u	Current number of items stored by this instance.	
`total_items`	32u	Total number of items stored during the life of this instance.	
`bytes`	64u	Current number of bytes used by this server to store items.	
`curr_connections`	32u	Current number of open connections.	
`total_connections`	32u	Total number of connections opened since the server started running.	
`connection_structures`	32u	Number of connection structures allocated by the server.	

Statistic	Data type	Description	Version
`cmd_get`	64u	Total number of retrieval requests (`get` operations).	
`cmd_set`	64u	Total number of storage requests (`set` operations).	
`get_hits`	64u	Number of keys that have been requested and found present.	
`get_misses`	64u	Number of items that have been requested and not found.	
`delete_hits`	64u	Number of keys that have been deleted and found present.	1.3.x
`delete_misses`	64u	Number of items that have been delete and not found.	1.3.x
`incr_hits`	64u	Number of keys that have been incremented and found present.	1.3.x
`incr_misses`	64u	Number of items that have been incremented and not found.	1.3.x
`decr_hits`	64u	Number of keys that have been decremented and found present.	1.3.x
`decr_misses`	64u	Number of items that have been decremented and not found.	1.3.x
`cas_hits`	64u	Number of keys that have been compared and swapped and found present.	1.3.x
`cas_misses`	64u	Number of items that have been compared and swapped and not found.	1.3.x
`cas_badvalue`	64u	Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value.	1.3.x
`evictions`	64u	Number of valid items removed from cache to free memory for new items.	
`bytes_read`	64u	Total number of bytes read by this server from network.	
`bytes_written`	64u	Total number of bytes sent by this server to network.	
`limit_maxbytes`	32u	Number of bytes this server is permitted to use for storage.	
`threads`	32u	Number of worker threads requested.	
`conn_yields`	64u	Number of yields for connections (related to the `-R` option).	1.4.0

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

15.3.4.2 `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
STAT total_malloced 67083616
END
```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

Statistic	Description	Version
chunk_size	Space allocated to each chunk within this slab class.	
chunks_per_page	Number of chunks within a single page for this slab class.	
total_pages	Number of pages allocated to this slab class.	
total_chunks	Number of chunks allocated to the slab class.	
used_chunks	Number of chunks allocated to an item..	
free_chunks	Number of chunks not yet allocated to items.	
free_chunks_end	Number of free chunks at the end of the last allocated page.	
get_hits	Number of get hits to this chunk	1.3.x
cmd_set	Number of set commands on this chunk	1.3.x
delete_hits	Number of delete hits to this chunk	1.3.x
incr_hits	Number of increment hits to this chunk	1.3.x
decr_hits	Number of decrement hits to this chunk	1.3.x
cas_hits	Number of CAS hits to this chunk	1.3.x
cas_badval	Number of CAS hits on this chunk where the existing value did not match	1.3.x
mem_requested	The true amount of memory of memory requested within this chunk	1.4.1

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

Statistic	Description	Version
`active_slabs`	Total number of slab classes allocated.	
`total_malloced`	Total amount of memory allocated to slab pages.	

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

15.3.4.3 `memcached` Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

Statistic	Description	
`number`	The number of items currently stored in this slab class.	
`age`	The age of the oldest item within the slab class, in seconds.	
`evicted`	The number of items evicted to make way for new entries.	
`evicted_time`	The time of the last evicted entry	
`evicted_nonzero`	The time of the last evicted non-zero entry	1.4.0
`outofmemory`	The number of items for this slab class that have triggered an out of memory error (only value when the `-M` command line option is in effect).	

Statistic	Description	
`tailrepairs`	Number of times the entries for a particular ID need repairing	

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions that others.

15.3.4.4 `memcached` Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
480 30
512 54
544 39
576 10065
```

Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

15.3.4.5 `memcached` Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the get, set, and del operations on theindividual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the `memcached` server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your `memcached` clients are using a large number of keys that do not exist in the server by comparing the `hit` and `get` or `del` counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

15.3.4.6 Using `memcached-tool`

The `memcached-tool`, located within the `scripts` directory within the `memcached` source directory. The tool provides convenient access to some reports and statistics from any `memcached` instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
  #  Item_Size  Max_age   Pages   Count   Full?  Evicted Evict_Time OOM
  1       80B      93s        1      20      no        0          0   0
  2      104B      93s        1      16      no        0          0   0
  3      136B     1335s       1      28      no        0          0   0
  4      176B     1335s       1      24      no        0          0   0
  5      224B     1335s       1      32      no        0          0   0
  6      280B     1335s       1      34      no        0          0   0
  7      352B     1335s       1      36      no        0          0   0
  8      440B     1335s       1      46      no        0          0   0
  9      552B     1335s       1      58      no        0          0   0
 10      696B     1335s       1      66      no        0          0   0
 11      872B     1335s       1      89      no        0          0   0
 12      1.1K     1335s       1     112      no        0          0   0
 13      1.3K     1335s       1     145      no        0          0   0
 14      1.7K     1335s       1     123      no        0          0   0
 15      2.1K     1335s       1     198      no        0          0   0
 16      2.6K     1335s       1     199      no        0          0   0
```

```
17     3.3K      1335s      1      229       no        0          0      0
18     4.1K      1335s      1      248       yes       36         2      0
19     5.2K      1335s      2      328       no        0          0      0
20     6.4K      1335s      2      316       yes       387        1      0
21     8.1K      1335s      3      381       yes       492        1      0
22    10.1K      1335s      3      303       yes       598        2      0
23    12.6K      1335s      5      405       yes       605        1      0
24    15.8K      1335s      6      384       yes       766        2      0
25    19.7K      1335s      7      357       yes       908      170      0
26    24.6K      1336s      7      287       yes      1012        1      0
27    30.8K      1336s      7      231       yes      1193      169      0
28    38.5K      1336s      4      104       yes      1323      169      0
29    48.1K      1336s      1       21       yes      1287        1      0
30    60.2K      1336s      1       17       yes      1093      169      0
31    75.2K      1337s      1       13       yes       713      168      0
32    94.0K      1337s      1       10       yes       278      168      0
33   117.5K      1336s      1        3       no        0          0      0
```

This output is the same if you specify the command as display:

```
shell> memcached-tool localhost:11211 display
  #   Item_Size   Max_age   Pages    Count    Full?   Evicted  Evict_Time  OOM
  1       80B        93s      1        20       no       0          0      0
  2      104B        93s      1        16       no       0          0      0
...
```

The output shows a summarized version of the output from the slabs statistics. The columns provided in the output are shown below:

- #: The slab number

- Item_Size: The size of the slab

- Max_age: The age of the oldest item in the slab

- Pages: The number of pages allocated to the slab

- Count: The number of items in this slab

- Full?: Whether the slab is fully populated

- Evicted: The number of objects evicted from this slab

- Evict_Time: The time (in seconds) since the last eviction

- OOM: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the stats command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211    Field       Value
        accepting_conns         1
                bytes         162
           bytes_read         485
        bytes_written        6820
           cas_badval           0
             cas_hits           0
           cas_misses           0
            cmd_flush           0
              cmd_get           4
              cmd_set           2
```

```
           conn_yields              0
 connection_structures             11
      curr_connections             10
            curr_items              2
             decr_hits              0
           decr_misses              1
           delete_hits              0
         delete_misses              0
             evictions              0
              get_hits              4
            get_misses              0
             incr_hits              0
           incr_misses              2
        limit_maxbytes       67108864
    listen_disabled_num              0
                   pid          12981
          pointer_size             32
         rusage_system       0.013911
           rusage_user       0.011876
               threads              4
                  time     1255518565
     total_connections             20
           total_items              2
                uptime            880
               version          1.4.2
```

15.3.5 memcached FAQ

15.3.5.1 Can memcached be run on a Windows environment?

No. Currently memcached is available only on the Unix/Linux platform. There is an unofficial port available, see http://www.codeplex.com/memcachedproviders.

15.3.5.2 What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In memcached 1.4.2 and later, you can change the maximum size of an object using the -I command line option.

For versions before this, to increase this size, you have to re-compile `memcached`. You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In `memcached` 1.4.2 and higher, you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. `memcached` is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

15.3.5.3. Is it true `memcached` will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. `memcached` plays no role in database writes, it is a method of caching data already read from the database in RAM.

15.3.5.4. Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with `memcached`, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

15.3.5.5. How is an event such as a crash of one of the `memcached` servers handled by the `memcached` client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see Section 15.3.2.5, "memcached Hashing/Distribution Types".

15.3.5.6. What is a recommended hardware configuration for a memcached server?

`memcached` has a very low processing overhead. All that is required is spare physical RAM capacity. A `memcached` server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with `memcached`.

To build and deploy a dedicated `memcached` server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

15.3.5.7. Is memcached more effective for video and audio as opposed to textual read/writes?

`memcached` works equally well for all kinds of data. To `memcached`, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in `memcached` is 1MB, but can be configured to be larger by using the `-I` option in `memcached` 1.4.2

and later, or by modifying the source in versions before 1.4.2. If you plan on using `memcached` with audio and video content, you will probably want to increase the maximum object size. Also remember that `memcached` is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

15.3.5.8. Can `memcached` work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# `memcached` library. For more information, see https://sourceforge.net/projects/memcacheddotnet/.

15.3.5.9. How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a `memcached` instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

15.3.5.10. How is the data handled when the `memcached` server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the `memcached` information). If you are using multiple `memcached` servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the `memcached` server that corresponds to the key you are trying to load.

15.3.5.11. How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and `memcached` unless your application (or, if you are using the MySQL UDFs for `memcached`, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of `memcached`, the information is only stored on one of the `memcached` instances anyway. The client uses the key value to determine which `memcached` instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

15.3.5.12. Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

15.3.5.13. Can we implement different types of `memcached` as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of `memcached` on a single server, and in your client configuration you choose the list of servers you want to use.

15.3.5.14. What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of `memcached` configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a `memcached` instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into `memcached`. Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that

information from MySQL with the code that requests the data from `memcached`. If the data cannot be loaded from `memcached`, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using `memcached` as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with `memcached`. Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the `memcached` servers, and there is no complex configuration; just add more servers to the list and let the client API and the `memcached` servers make the decisions.

Chapter 16 Replication

Table of Contents

Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous - slaves need not be connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

For answers to some questions often asked by those who are new to MySQL Replication, see Section A.13, "MySQL 5.1 FAQ: Replication".

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.

- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.

- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.

- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see Chapter 17, *MySQL Cluster NDB 6.1 - 7.1*).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see Section 16.1.1, "How to Set Up Replication".

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see Section 16.1.2, "Replication Formats". From MySQL 5.1.12 to MySQL 5.1.28, mixed format is the default. Beginning with MySQL 5.1.29, statement-based format is the default.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see Section 16.1.3, "Replication and Binary Logging Options and Variables".

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see Section 16.3, "Replication Solutions".

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see Section 16.4, "Replication Notes and Tips".

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see Section 16.2, "Replication Implementation".

16.1 Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as "events" to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The master is "dumb" in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then "catch up" by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and

position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's `master.info` file.

This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, Section 16.1.1, "How to Set Up Replication", deals with the configuration of the systems and provides methods for copying data between the master and slaves.

- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in Section 16.1.2, "Replication Formats".

- Detailed information on the different configuration options and variables that apply to replication is provided in Section 16.1.3, "Replication and Binary Logging Options and Variables".

- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see Section 16.1.4, "Common Replication Administration Tasks".

16.1.1 How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See Section 16.1.1.1, "Setting the Replication Master Configuration".

- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See Section 16.1.1.2, "Setting the Replication Slave Configuration".

- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See Section 16.1.1.3, "Creating a User for Replication".

- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See Section 16.1.1.4, "Obtaining the Replication Master Binary Log Coordinates".

- If you already have data on your master and you want to use it to synchronize your slave, you will need to create a data snapshot. You can create a snapshot using `mysqldump` (see Section 16.1.1.5, "Creating a Data Snapshot Using mysqldump") or by copying the data files directly (see Section 16.1.1.6, "Creating a Data Snapshot Using Raw Data Files").

- You will need to configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See Section 16.1.1.10, "Setting the Master Configuration on the Slave".

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see Section 16.1.1.7, "Setting Up Replication with New Master and Slaves".

- If you are already running a MySQL server, and therefore already have data that must be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shut down your MySQL server for a short period during the process, see Section 16.1.1.8, "Setting Up Replication with Existing Data".

- If you are adding slaves to an existing replication environment, you can set up the slaves without affecting the master. See Section 16.1.1.9, "Introducing Additional Slaves to an Existing Replication Environment".

If you will be administering MySQL replication servers, we suggest that you read this entire chapter through and try all statements mentioned in Section 13.4.1, "SQL Statements for Controlling Master Servers", and Section 13.4.2, "SQL Statements for Controlling Slave Servers". You should also familiarize yourself with the replication startup options described in Section 16.1.3, "Replication and Binary Logging Options and Variables".

> **Note**
>
> Note that certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege, it might not be possible to enable replication.

16.1.1.1 Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, this part of master setup requires a server restart.

Binary logging *must* be enabled on the master because the binary log is the basis for sending data changes from the master to its slaves. If binary logging is not enabled, replication will not be possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and $(2^{32})-1$. How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the `my.cnf` or `my.ini` file. Add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

> **Note**
>
> If you omit `server-id` (or set it explicitly to its default value of 0), a master refuses connections from all slaves.

> **Note**
>
> For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use

> `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

> **Note**
>
> Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, your slave will not able to communicate with the master and replication will fail.

16.1.1.2 Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, you should shut down your slave server and edit the configuration to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

> **Note**
>
> If you omit `server-id` (or set it explicitly to its default value of 0), a slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave, you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

16.1.1.3 Creating a User for Replication

Each slave must connect to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You may wish to create a different account for each slave, or connect to the master using the same account for each slave.

You need not create an account specifically for replication. However, you should be aware that the user name and password will be stored in plain text within the `master.info` file (see Section 16.2.2.2, "Slave Status Logs"). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.mydomain.com';
```

See Section 13.7.1, "Account Management Statements", for more information on statements for manipulation of user accounts.

16.1.1.4 Obtaining the Replication Master Binary Log Coordinates

To configure replication on the slave you must determine the master's current coordinates within its binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the FLUSH TABLES WITH READ LOCK statement:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

   For InnoDB tables, note that FLUSH TABLES WITH READ LOCK also blocks COMMIT operations.

   > **Warning**
   >
   > Leave the client from which you issued the FLUSH TABLES statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the SHOW MASTER STATUS statement to determine the current binary log file name and position:

   ```
   mysql > SHOW MASTER STATUS;
   +------------------+----------+--------------+------------------+
   | File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
   +------------------+----------+--------------+------------------+
   | mysql-bin.000003 | 73       | test         | manual,mysql     |
   +------------------+----------+--------------+------------------+
   ```

   The File column shows the name of the log file and Position shows the position within the file. In this example, the binary log file is mysql-bin.000003 and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

   If the master has been running previously without binary logging enabled, the log file name and position values displayed by SHOW MASTER STATUS or mysqldump --master-data will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string ('') and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs be to synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to Section 16.1.1.5, "Creating a Data

Snapshot Using mysqldump", or Section 16.1.1.6, "Creating a Data Snapshot Using Raw Data Files". The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

16.1.1.5 Creating a Data Snapshot Using mysqldump

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool to create a dump of all the databases you want to replicate. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

The example shown here dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually (using `FLUSH TABLES WITH READ LOCK`) prior to running `mysqldump`, then exiting or running UNLOCK TABLES from the second session to release the locks. You must also obtain binary log position information matching the snapshot, using `SHOW MASTER STATUS`, and use this to issue the appropriate `CHANGE MASTER TO` statement when starting the slave.

When choosing databases to include in the dump, remember that you need to filter out databases on each slave that you do not want to include in the replication process.

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.

16.1.1.6 Creating a Data Snapshot Using Raw Data Files

If your database is large, copying the raw data files can be more efficient than using `mysqldump` and importing the file on each slave. This technique skips the overhead of updating indexes as the `INSERT` statements are replayed.

Using this method with tables in storage engines with complex caching or logging algorithms requires extra steps to produce a perfect "point in time" snapshot: the initial copy command might leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

This method also does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be later used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See Section 23.2, "MySQL Enterprise Backup Overview" for detailed information.

Otherwise, use the cold backup technique to obtain a reliable binary snapshot of `InnoDB` tables: copy all data files after doing a slow shutdown of the MySQL Server.

To create a raw data snapshot of `MyISAM` tables, you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases, copy only those files that relate to those tables. (For `InnoDB`, all tables in all databases are stored in the system tablespace files, unless you have the `innodb_file_per_table` option enabled.)

You might want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.

- The `master.info` file.

- The master's binary log files.

- Any relay log files.

To get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See Section 16.1.1.4, "Obtaining the Replication Master Binary Log Coordinates".

2. In a separate session, shut down the master server:

   ```
   shell> mysqladmin shutdown
   ```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

   ```
   shell> tar cf /tmp/db.tar ./data
   shell> zip -r /tmp/db.zip ./data
   shell> rsync --recursive ./data /tmp/dbdata
   ```

4. Restart the master server.

If you are not using `InnoDB` tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See Section 16.1.1.4, "Obtaining the Replication Master Binary Log Coordinates".

2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

   ```
   shell> tar cf /tmp/db.tar ./data
   shell> zip -r /tmp/db.zip ./data
   shell> rsync --recursive ./data /tmp/dbdata
   ```

3. In the client where you acquired the read lock, release the lock:

   ```
   mysql> UNLOCK TABLES;
   ```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

16.1.1.7 Setting Up Replication with New Master and Slaves

The easiest and most straightforward method for setting up replication is to use new master and slave servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See Section 16.1.1.1, "Setting the Replication Master Configuration".

2. Start up the MySQL master.

3. Set up a user. See Section 16.1.1.3, "Creating a User for Replication".

4. Obtain the master status information. See Section 16.1.1.4, "Obtaining the Replication Master Binary Log Coordinates".

5. On the master, release the read lock:

   ```
   mysql> UNLOCK TABLES;
   ```

6. On the slave, edit the MySQL configuration. See Section 16.1.1.2, "Setting the Replication Slave Configuration".

7. Start up the MySQL slave.

8. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See Section 16.1.1.10, "Setting the Master Configuration on the Slave".

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

16.1.1.8 Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See Section 16.1.1.3, "Creating a User for Replication".

2. If you have not already configured the `server-id` and enabled binary logging on the master server, you will need to shut it down to configure these options. See Section 16.1.1.1, "Setting the Replication Master Configuration".

If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see Section 16.1.1.4, "Obtaining the Replication Master Binary Log Coordinates") before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see Section 16.1.1.6, "Creating a Data Snapshot Using Raw Data Files".

3. If your master server is already correctly configured, obtain its status (see Section 16.1.1.4, "Obtaining the Replication Master Binary Log Coordinates") and then use `mysqldump` to take a snapshot (see Section 16.1.1.5, "Creating a Data Snapshot Using mysqldump") or take a raw snapshot of the live server using the guide in Section 16.1.1.6, "Creating a Data Snapshot Using Raw Data Files".

4. Update the configuration of the slave. See Section 16.1.1.2, "Setting the Replication Slave Configuration".

5. The next step depends on how you created the snapshot of data on the master.

   If you used `mysqldump`:

   a. Start the slave, using the `--skip-slave-start` option so that replication does not start.

   b. Import the dump file:

   ```
   shell> mysql < fulldb.dump
   ```

   If you created a snapshot using the raw data files:

   a. Extract the data files into your slave data directory. For example:

   ```
   shell> tar xvf dbdump.tar
   ```

   You may need to set permissions and ownership on the files so that the slave server can access and modify them.

   b. Start the slave, using the `--skip-slave-start` option so that replication does not start.

6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see Section 16.1.1.10, "Setting the Master Configuration on the Slave".

7. Start the slave threads:

   ```
   mysql> START SLAVE;
   ```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

> **Note**
>
> The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See Section 16.1.3, "Replication and Binary Logging Options and Variables", for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

16.1.1.9 Introducing Additional Slaves to an Existing Replication Environment

To add another slave to an existing replication configuration, you can do so without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

   ```
   shell> mysqladmin shutdown
   ```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

   A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

   ```
   071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
   replication may break when this MySQL server acts as a slave and has his hostname
   changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
   071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525'
   (relay_log_pos 22940879)
   071118 16:44:10 [ERROR] Could not find target log during relay log initialization
   071118 16:44:10 [ERROR] Failed to initialize the master info structure
   ```

   This is due to the fact that, if the `--relay-log` option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` option is not used. See Section 16.1.3, "Replication and Binary Logging Options and Variables", for more information about these options.)

   To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`.) If this is not feasible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`.) Alternatively—if you have already tried to start

the new slave (after following the remaining steps in this section) and have encountered errors like those described previously—then perform the following steps:

a. If you have not already done so, issue a `STOP SLAVE` on the new slave.

   If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.

b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.

c. Proceed with the remaining steps in this section.

3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave if they were not located in the data directory. These files hold the current log coordinates for the master's binary log and the slave's relay log.

4. Start the existing slave.

5. On the new slave, edit the configuration and give the new slave a unique `server-id` not used by the master or any of the existing slaves.

6. Start the new slave. The slave will use the information in its `master.info` file to start the replication process.

16.1.1.10 Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
    ->     MASTER_HOST='master_host_name',
    ->     MASTER_USER='replication_user_name',
    ->     MASTER_PASSWORD='replication_password',
    ->     MASTER_LOG_FILE='recorded_log_file_name',
    ->     MASTER_LOG_POS=recorded_log_position;
```

> **Note**
>
> Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see Section 13.4.2.1, "CHANGE MASTER TO Syntax".

16.1.2 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to

the standard statement-based binary logging format. In MySQL 5.1.4 and earlier, binary logging and replication used this format exclusively.

- Row-based binary logging logs changes in individual table rows. When used with MySQL replication, this is known as *row-based replication* (often abbreviated as *RBR*). In row-based replication, the master writes *events* to the binary log that indicate how individual table rows are changed.

- As of MySQL 5.1.8, the server can change the binary logging format in real time according to the type of event using *mixed-format logging*.

  When the mixed format is in effect, statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described later. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see Section 5.4.4.3, "Mixed Binary Logging Format".

From MySQL 5.1.12 to MySQL 5.1.28, mixed format is the default. Beginning with MySQL 5.1.29, statement-based format is the default.

MySQL Cluster.   The default binary logging format in all MySQL Cluster NDB 6.x and 7.x releases is `ROW`. MySQL Cluster Replication always uses row-based replication, and the `NDBCLUSTER` storage engine is incompatible with statement-based replication. Using `NDBCLUSTER` sets row-based logging format automatically. See Section 17.6.2, "General Requirements for MySQL Cluster Replication", for more information.

Starting with MySQL 5.1.20, when using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see Section 5.4.4.3, "Mixed Binary Logging Format".

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see Section 13.7.4.1, "SET Syntax for Variable Assignment".

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See Section 5.4.4.2, "Setting The Binary Log Format".

You must have the `SUPER` privilege to set the global `binlog_format` value. Starting with MySQL 5.1.29, you must have the `SUPER` privilege to set either the global or session `binlog_format` value. (Bug #39106)

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see Section 16.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see Section 19.7, "Binary Logging of Stored Programs".

16.1.2.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when

performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- Advantages of statement-based replication

- Disadvantages of statement-based replication

- Advantages of row-based replication

- Disadvantages of row-based replication

Advantages of statement-based replication

- Proven technology that has existed in MySQL since 3.23.

- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.

- Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**
  Not all statements which modify data (such as `INSERT DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:

  - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See Section 16.4.1.12, "Replication of Invoked Features", for more information.

  - `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See Section 16.4.1.16, "Replication and LIMIT".

  - Statements using any of the following functions cannot be replicated properly using statement-based replication:

    - `LOAD_FILE()`

    - `UUID()`, `UUID_SHORT()`

    - `USER()`

    - `FOUND_ROWS()`

    - `SYSDATE()` (unless both the master and the slave are started with the `--sysdate-is-now` option)

    - `GET_LOCK()`

    - `IS_FREE_LOCK()`

    - `IS_USED_LOCK()`

    - `MASTER_POS_WAIT()`

- `RAND()`

- `RELEASE_LOCK()`

- `SLEEP()`

- `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `NOW()` and so forth.

For more information, see Section 16.4.1.15, "Replication and System Functions".

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.

- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.

- For `InnoDB`: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.

- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.

- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See Section 16.4.1.29, "Slave Errors During Replication".

- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.

- Deterministic UDFs must be applied on the slaves.

- Table definitions must be (nearly) identical on master and slave. See Section 16.4.1.10, "Replication with Differing Table Definitions on Master and Slave", for more information.

Advantages of Row-Based Replication

- All changes can be replicated. This is the safest form of replication.

  For MySQL versions earlier than 5.1.14, DDL (Data Definition Language) statements such as `CREATE TABLE` are replicated using statement-based replication, while DML statements, as well as `GRANT` and `REVOKE` statements, are replicated using row-based replication.

  In MySQL 5.1.14 and later, the `mysql` database is not replicated. The `mysql` database is instead seen as a node-specific database. Row-based replication is not supported on tables in this database. Instead, statements that would normally update this information—such as `GRANT`, `REVOKE` and the manipulation

of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.

- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:

  - `INSERT ... SELECT`

  - `INSERT` statements with `AUTO_INCREMENT`

  - `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.

- Fewer row locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

Disadvantages of Row-Based Replication

- RBR tends to generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems.

- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.

- You cannot examine the logs to see what statements were executed, nor can you see on the slave what statements were received from the master and executed.

  However, beginning with MySQL 5.1.29, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

- For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

- Formerly, when performing a bulk operation that includes nontransactional storage engines, changes were applied as the statement executed. With row-based logging, this meant that the binary log was written while the statement was running. On the master, this does not cause problems with concurrency, because tables are locked until the bulk operation terminates. On the slave server, tables were not locked while the slave applied changes, because the slave did not know that those changes were part of a bulk operation.

  In such cases, if you retrieved data from a table on the master (for example, using `SELECT * FROM table_name`), the server waited for the bulk operation to complete before executing the `SELECT` statement, because the table was read-locked. On the slave, the server did not wait (because there was

no lock). This meant that, until the bulk operation on the slave completed, different results were obtained for the same `SELECT` query on the master and on the slave.

This issue was resolved in MySQL 5.1.24. (Bug #29020)

16.1.2.2 Usage of Row-Based Logging and Replication

Major changes in the replication environment and in the behavior of applications can result from using row-based logging (RBL) or row-based replication (RBR) rather than statement-based logging or replication. This section describes a number of issues known to exist when using row-based logging or replication, and discusses some best practices for taking advantage of row-based logging and replication.

For additional information, see Section 16.1.2, "Replication Formats", and Section 16.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

For information about issues specific to MySQL Cluster Replication (which depends on row-based replication), see Section 17.6.3, "Known Issues in MySQL Cluster Replication".

- **RBL, RBR, and temporary tables.**   As noted in Section 16.4.1.23, "Replication and Temporary Tables", temporary tables are not replicated when using row-based format. When mixed format is in effect, "safe" statements involving temporary tables are logged using statement-based format. For more information, see Section 16.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

  Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

- **RBL and the BLACKHOLE storage engine.**   Prior to MySQL 5.1.29, `DELETE` and `UPDATE` statements for `BLACKHOLE` tables did not work with RBL. (Bug #38360)

- **RBL and synchronization of nontransactional tables.**   When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log if the statement is an initial nontransactional statement (occurring in the transaction before any transactional statements). When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave's copy of the table.)

- **Latency and binary log size.**   Because RBL writes changes for each row to the binary log, its size can increase quite rapidly. In a replication environment, this can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.

- **Reading the binary log.**   `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see Section 13.7.6.1, "BINLOG Syntax"). This statement displays an event in printable form, but as a base 64-encoded string the meaning of which is not evident. As of MySQL 5.1.28, when invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log in a manner that is easily human readable. This is helpful when binary log events were written in row-based format if you want to read or recover from a replication or database failure using the contents of the binary log. For more information, see Section 4.6.7.2, "mysqlbinlog Row Event Display".

- **Binary log execution errors and slave_exec_mode.**   If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with

RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see Section 5.1.4, "Server System Variables".

> **Note**
>
> `slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which `IDEMPOTENT` is the default value (see Section 17.6, "MySQL Cluster Replication").
>
> For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.

- **Lack of binary log checksums.**   RBL uses no checksums. This means that network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption, you may want to consider using SSL, which adds another layer of checksumming, for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also Section 13.4.2.1, "CHANGE MASTER TO Syntax", for general information about setting up MySQL with SSL.

- **Filtering based on server ID not supported.**   A common practice is to filter out changes on some slaves by using a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements, a simple example of such a clause being `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. If you must use the `server_id` system variable for statement filtering, you must also use `--binlog_format=STATEMENT`.

- **Database-level replication options.**   The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Because of this, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact that your choice of replication format has on how they operate, see Section 16.1.3, "Replication and Binary Logging Options and Variables".

- **RBL, nontransactional tables, and stopped slaves.**   When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database may reaches an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format.

  Use of `STOP SLAVE` (or `STOP SLAVE SQL_THREAD` in MySQL 5.1.55 and later) prior to shutting down the slave MySQL server helps prevent such issues from occurring, and is always recommended regardless of the logging format or storage engines employed.

16.1.2.3 Determination of Safe and Unsafe Statements in Binary Logging

When speaking of the "safeness" of a statement in MySQL Replication, we are referring to whether a statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see Nondeterministic functions not considered unsafe, later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see Section 16.4.1.13, "Replication and Floating-Point Values").

Handling of safe and unsafe statements.   A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- No distinction is made in the treatment of safe and unsafe statements when the binary logging mode is `ROW`.

- If the binary logging format is `MIXED`, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.

- If the binary logging format is `STATEMENT`, statements flagged as being unsafe generate a warning to this effect. (Safe statements are logged normally.)

For more information, see Section 16.1.2, "Replication Formats".

Statements considered unsafe.
Statements having the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.**
  These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

  In MySQL 5.1.43 and later, `RAND()` is also treated as unsafe. (Bug #11757207, Bug #49222)

  Nondeterministic functions not considered unsafe.   Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and `LAST_INSERT_ID()`

  For more information, see Section 16.4.1.15, "Replication and System Functions".

- **References to system variables.**   Most system variables are not replicated correctly using the statement-based format. For exceptions, see Section 5.4.4.3, "Mixed Binary Logging Format".

  See Section 16.4.1.38, "Replication and Variables".

- **UDFs.**   Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.

- **Updates a table having an AUTO_INCREMENT column.**   This is unsafe because the order in which the rows are updated may differ on the master and the slave.

  In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

  For more information, see Section 16.4.1.1, "Replication and AUTO_INCREMENT".

- **INSERT DELAYED statement.**   This statement is considered unsafe because the insertion of the rows may interleave with concurrently executing statements.

- **INSERT ... ON DUPLICATE KEY UPDATE statements on tables with multiple primary or unique keys.**   When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

  Thus, such statements are considered unsafe.

- **Updates using LIMIT.**   The order in which rows are retrieved is not specified.

  See Section 16.4.1.16, "Replication and LIMIT".

- **Accesses or references log tables.**   The contents of the system log table may differ between master and slave.

- **Nontransactional operations after transactional operations.**   Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

  For more information, see Section 16.4.1.35, "Replication and Transactions".

- **Accesses or references self-logging tables.**   All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.

- **LOAD DATA INFILE statements.**   Beginning with MySQL 5.1.50, `LOAD DATA INFILE` is considered unsafe, it causes a warning in statement-based mode, and a switch to row-based format when using mixed-format logging. See Section 16.4.1.17, "Replication and LOAD DATA INFILE".

For additional information, see Section 16.4.1, "Replication Features and Issues".

16.1.3 Replication and Binary Logging Options and Variables

The next few sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` option.

Command-Line Format	`--server-id=#`	
System Variable	**Name**	`server_id`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`integer`
	Default	`0`
	Min Value	`0`
	Max Value	`4294967295`

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see Section 16.1.3.2, "Replication Master Options and Variables", and Section 16.1.3.3, "Replication Slave Options and Variables".

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. "Unique", means that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

If you omit `--server-id`, the default ID is 0, in which case the master refuses connections from all slaves, and slaves refuse to connect to the master. In MySQL 5.1, whether the server ID is set to 0 explicitly or the default is allowed to be used, the server sets the `server_id` system variable to 1; this is a known issue that is fixed in MySQL 5.7.

For more information, see Section 16.1.1.2, "Setting the Replication Slave Configuration".

16.1.3.1 Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

Table 16.1 Summary of Replication options and variables in MySQL 5.1

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
`abort-slave-event-count`		
Yes	No	No
Yes		No
DESCRIPTION: Option used by mysql-test for debugging and testing of replication		
`Com_change_master`		
No	No	Yes
No	Both	No
DESCRIPTION: Count of CHANGE MASTER TO statements		
`Com_show_master_status`		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW MASTER STATUS statements		
`Com_show_new_master`		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW NEW MASTER statements		
`Com_show_slave_hosts`		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW SLAVE HOSTS statements		
`Com_show_slave_status`		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW SLAVE STATUS statements		
`Com_slave_start`		
No	No	Yes
No	Both	No
DESCRIPTION: Count of START SLAVE statements		
`Com_slave_stop`		
No	No	Yes

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
No	Both	No
DESCRIPTION: Count of STOP SLAVE statements		
	disconnect-slave-event-count	
Yes	No	No
Yes		No
DESCRIPTION: Option used by mysql-test for debugging and testing of replication		
	have_row_based_replication	
No	Yes	No
No	Global	No
DESCRIPTION: Shows whether row-based replication is supported		
	init_slave	
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Statements that are executed when a slave connects to a master		
	log-slave-updates	
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Tells the slave to log the updates performed by its SQL thread to its own binary log		
	log_slave_updates	
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Whether the slave should log the updates performed by its SQL thread to its own binary log. Read-only; set using the --log-slave-updates server option.		
	master-connect-retry	
Yes	No	No
Yes		No
DESCRIPTION: Number of seconds the slave thread will sleep before retrying to connect to the master in case the master goes down or the connection is lost		
	master-host	
Yes	No	No
Yes		No
DESCRIPTION: Master host name or IP address for replication		
	master-info-file	
Yes	No	No
Yes		No

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
DESCRIPTION: The location and name of the file that remembers the master and where the I/O replication thread is in the master's binary logs		
master-password		
Yes	No	No
Yes		No
DESCRIPTION: The password the slave thread will authenticate with when connecting to master		
master-port		
Yes	No	No
Yes		No
DESCRIPTION: The port the master is listening on		
master-retry-count		
Yes	No	No
Yes		No
DESCRIPTION: Number of tries the slave makes to connect to the master before giving up		
master-ssl		
Yes	No	No
Yes		No
DESCRIPTION: Enable the slave to connect to the master using SSL		
master-ssl-ca		
Yes	No	No
Yes		No
DESCRIPTION: Master SSL CA file; applies only if master-ssl is enabled		
master-ssl-capath		
Yes	No	No
Yes		No
DESCRIPTION: Master SSL CA path; applies only if master-ssl is enabled		
master-ssl-cert		
Yes	No	No
Yes		No
DESCRIPTION: Master SSL certificate file name; applies only if master-ssl is enabled		
master-ssl-cipher		
Yes	No	No
Yes		No
DESCRIPTION: Master SSL cipher; applies only if master-ssl is enabled		
master-ssl-key		

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
Yes	No	No
Yes		No
DESCRIPTION: Master SSL key file name; applies only if master-ssl is enabled		
	master-user	
Yes	No	No
Yes		No
DESCRIPTION: The user name the slave thread will use for authentication when connecting to master. The user must have FILE privilege. If the master user is not set, user test is assumed. The value in master.info will take precedence if it can be read		
	relay-log	
Yes	Yes	No

	slave-load-tmpdir	
Yes	Yes	No

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
Yes	Global	No
DESCRIPTION: The location where the slave should put its temporary files when replicating a LOAD DATA INFILE statement		
	slave-max-allowed-packet	
Yes	No	No
Yes		No
DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet.		
	slave_net_timeout	
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Number of seconds to wait for more data from a master/slave connection before aborting the read		
	slave-skip-errors	
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Tells the slave thread to continue replication when a query returns an error from the provided list		
	slave_compressed_protocol	
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Use compression on master/slave protocol		
	slave_exec_mode	
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Allows for switching the slave thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is the default, except for MySQL Cluster, where IDEMPOTENT is always used		
	Slave_heartbeat_period	
No	No	Yes
No	Global	No
DESCRIPTION: The slave's replication heartbeat interval, in seconds		
	slave_max_allowed_packet	
No	Yes	No
No	Global	Yes
DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet.		

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
`Slave_open_temp_tables`		
No	No	Yes
No	Global	No
DESCRIPTION: Number of temporary tables that the slave SQL thread currently has open		
`Slave_retried_transactions`		
No	No	Yes
No	Global	No
DESCRIPTION: The total number of times since startup that the replication slave SQL thread has retried transactions		
`Slave_running`		
No	No	Yes
No	Global	No
DESCRIPTION: The state of this server as a replication slave (slave I/O thread status)		
`slave_transaction_retries`		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Number of times the slave SQL thread will retry a transaction in case it failed with a deadlock or elapsed lock wait timeout, before giving up and stopping		
`slave_type_conversions`		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Controls type conversion mode on replication slave. Value is a list of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set to an empty string to disallow type conversions between master and slave.		
`sql_slave_skip_counter`		
No	Yes	No
No	Global	Yes
DESCRIPTION: Number of events from the master that a slave server should skip. Not compatible with GTID replication.		
`sync_binlog`		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Synchronously flush binary log to disk after every #th event		

Section 16.1.3.2, "Replication Master Options and Variables", provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves, see Section 16.1.3.3, "Replication Slave Options and Variables".

DESCRIPTION: Option used by mysql-test for debugging and testing of replication		

Section 16.1.3.4, "Binary Log Options and Variables", provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.4.4, "The Binary Log".

For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.4, "Server System Variables".

For a table showing *all* command-line options, system and status variables used with `mysqld`, see Section 5.1.1, "Server Option and Variable Reference".

16.1.3.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the command line or in an option file. You can specify system variable values using `SET`.

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see Section 16.1.3.4, "Binary Log Options and Variables".

System Variables Used on Replication Masters

The following system variables are used in controlling replication masters:

- `auto_increment_increment`

System Variable	Name	`auto_increment_increment`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	**Type**	`integer`
	Default	`1`
	Min Value	`1`
	Max Value	`65535`

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value gives rise to an error, and the actual value of the variable remains unchanged.

> **Note**
>
> `auto_increment_increment` is supported for use with `NDB` tables beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- auto_increment_increment controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 1     |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
  Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)
```

- auto_increment_offset determines the starting point for the AUTO_INCREMENT column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for auto_increment_increment:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)
```

```
mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
|   5 |
|  15 |
|  25 |
|  35 |
+-----+
4 rows in set (0.02 sec)
```

If the value of auto_increment_offset is greater than that of auto_increment_increment, the value of auto_increment_offset is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an AUTO_INCREMENT column, the results may seem counterintuitive because the series of AUTO_INCREMENT values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the AUTO_INCREMENT column. In other words, the series is calculated like so:

$$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$$

where N is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
|  35 |
|  45 |
|  55 |
|  65 |
```

```
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series 5 + *N* × 10, that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See Section 16.4.1.1, "Replication and AUTO_INCREMENT".

- `auto_increment_offset`

System Variable	Name	`auto_increment_offset`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	`integer`
	Default	`1`
	Min Value	`1`
	Max Value	`65535`

This variable has a default value of 1. For particulars, see the description for `auto_increment_increment`.

> **Note**
>
> `auto_increment_offset` is supported for use with `NDB` tables beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

16.1.3.3 Replication Slave Options and Variables

Startup Options for Replication Slaves

System Variables Used on Replication Slaves

This section describes the server options and system variables that apply to slave replication servers. You can specify the options either on the command line or in an option file. Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

Server ID. On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. "Unique" means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

> **Important**
>
> Certain `--master-xxx` options are handled in a special way to ensure that the active replication configuration is not inadvertently altered or affected:
>
> - `--master-host`
> - `--master-user`
> - `--master-password`
> - `--master-port`
> - `--master-connect-retry`
> - `--master-ssl`
> - `--master-ssl-ca`
> - `--master-ssl-capath`
> - `--master-ssl-cert`
> - `--master-ssl-cipher`
> - `--master-ssl-key`
>
> Before MySQL 5.1.17, these options are silently ignored if given unless there is no `master.info` file. If that file exists, the MySQL server has already previously been configured for replication, so the information in the file is used instead. Because the server gives an existing `master.info` file precedence over the startup options just described, you might elect not to use startup options for these values at all, and instead to specify the replication parameters associated with them by using the `CHANGE MASTER TO` statement. See Section 13.4.2.1, "CHANGE MASTER TO Syntax".
>
> Beginning with MySQL 5.1.17, these options are deprecated and have no effect when `mysqld` is started. If they are used, an appropriate warning is written to the error log. Instead, you *must* use `CHANGE MASTER TO` to set the values corresponding to the deprecated options. These options are removed in MySQL 5.5.

The `master.info` file format in MySQL 5.1 includes as its first line the number of lines in the file. (See Section 16.2.2, "Replication Relay and Status Logs".) If you upgrade an older server (before MySQL 4.1.1) to a newer version, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to an older version, you should remove the first line manually before starting the older server for the first time.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication

slave for the very first time, when you use `CHANGE MASTER TO`, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

Because the server uses `master.info` file contents and ignores any startup options that correspond to the values listed in the file, if you start the slave server with different values of the startup options that correspond to values in the file, the different values have no effect. To use different values, the preferred method is to use the `CHANGE MASTER TO` statement to reset the values while the slave is running. Alternatively, you can stop the server, remove the `master.info` file, and restart the server with different option values.

Suppose that you specify this option in your `my.cnf` file to configure a pre-5.1.17 slave server:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host value of `some_other_host`, the change has no effect. Instead, use `CHANGE MASTER TO` to change the value.

This example shows a more extensive use of startup options to configure a pre-5.1.17 slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

As of 5.1.17, the `master-xxx` options are ignored and result in warnings in the error log.

Startup Options for Replication Slaves

The following list describes startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--abort-slave-event-count`

Command-Line Format	`--abort-slave-event-count=#`	
Permitted Values	Type	`integer`
	Default	0
	Min Value	0

  When this option is set to some positive integer `value` other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, `value` log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--disconnect-slave-event-count`

Command-Line Format	`--disconnect-slave-event-count=#`	
Permitted Values	**Type**	`integer`
	Default	`0`

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--log-slave-updates`

Command-Line Format	`--log-slave-updates`	
System Variable	**Name**	`log_slave_updates`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	**Type**	`boolean`
	Default	`OFF`

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, `A` serves as the master for the slave `B`, and `B` serves as the master for the slave `C`. For this to work, `B` must be both a master *and* a slave. You must start both `A` and `B` with `--log-bin` to enable binary logging, and `B` with the `--log-slave-updates` option so that updates received from `A` are logged by `B` to its binary log.

When using MySQL Cluster Replication prior to MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13, records for "empty" epochs—that is, epochs in which no changes to `NDBCLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled (Bug #37472). Beginning with MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.3, it is possible to re-enable the older behavior by using the `--ndb-log-empty-epochs` option.

> **Note**
>
> The `--ndb-log-empty-epochs` option was first implemented in MySQL Cluster NDB 6.3.21 and MySQL Cluster NDB 6.4.1, but did not work correctly before the versions cited previously.

- `--log-slow-slave-statements`

Introduced	5.1.21

Command-Line Format	`--log-slow-slave-statements`	
Permitted Values	**Type**	`boolean`
	Default	`OFF`

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

This option was added in MySQL 5.1.21.

- `--log-warnings[=level]`

Command-Line Format	`--log-warnings[=#]`	
System Variable	**Name**	`log_warnings`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	**Type**	`integer`
	Default	`1`
	Min Value	`0`
	Max Value	`4294967295`
Permitted Values (64-bit platforms)	**Type**	`integer`
	Default	`1`
	Min Value	`0`
	Max Value	`18446744073709547520`

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled (1) by default; to disable it, use `--log-warnings=0`. Aborted connections are not logged to the error log unless the value is greater than 1.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-connect-retry=seconds`

Deprecated	5.1.17	
Command-Line Format	`--master-connect-retry=#`	
Permitted Values	**Type**	`integer`
	Default	`60`

The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence

if it can be read. If not set, the default is 60. Connection retries are not invoked until the slave times out reading data from the master according to the value of `--slave-net-timeout`. The number of reconnection attempts is limited by the `--master-retry-count` option.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `slave-max-allowed-packet=bytes`

Introduced	5.1.64	
Command-Line Format	`--slave-max-allowed-packet=#`	
Permitted Values	**Type**	`integer`
	Default	`1073741824`
	Min Value	`1024`
	Max Value	`1073741824`

In MySQL 5.1.64 and later, this option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. (Bug #12400221, Bug #60926)

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--master-host=host_name`

Deprecated	5.1.17	
Command-Line Format	`--master-host=name`	
Permitted Values	**Type**	`string`

The host name or IP address of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-info-file=file_name`

Command-Line Format	`--master-info-file=file_name`	
Permitted Values	**Type**	`file name`
	Default	`master.info`

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see Section 16.2.2.2, "Slave Status Logs".

- `--master-password=password`   1799

Deprecated	5.1.17	
Command-Line Format	`--master-password=name`	
Permitted Values	Type	`string`

The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-port=port_number`

Deprecated	5.1.17	
Command-Line Format	`--master-port=#`	
Permitted Values	Type	`integer`
	Default	`3306`

The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-retry-count=count`

Command-Line Format	`--master-retry-count=#`	
Permitted Values (32-bit platforms)	Type	`integer`
	Default	`86400`
	Min Value	`0`
	Max Value	`4294967295`
Permitted Values (64-bit platforms)	Type	`integer`
	Default	`86400`
	Min Value	`0`
	Max Value	`18446744073709551615`

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `--master-connect-retry` option (or the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement) and reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means "infinite"; the slave attempts to connect forever.

- `--master-ssl`, `--master-ssl-ca=file_name`, `--master-ssl-capath=directory_name`, `--master-ssl-cert=file_name`, `--master-ssl-cipher=cipher_list`, `--master-ssl-key=file_name`

These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl`, `--ssl-ca`, `--ssl-capath`, `--ssl-cert`, `--ssl-cipher`, `--ssl-key` options that are described in Section 6.4.5, "Command Options for Secure Connections". The values in the `master.info` file take precedence if they can be read.

These options are deprecated as of MySQL 5.1.17 and are removed in MySQL 5.5.

- `--master-user=user_name`

Deprecated	5.1.17	
Command-Line Format	`--master-user=name`	
Permitted Values	**Type**	`string`
	Default	`test`

The user name of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` privilege. The value in the `master.info` file takes precedence if it can be read. If the master user name is not set, the name `test` is assumed.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--max-relay-log-size=size`

Command-Line Format	`--max_relay_log_size=#`	
System Variable	**Name**	`max_relay_log_size`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`integer`
	Default	0
	Min Value	0
	Max Value	`1073741824`

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see Section 16.2.2.1, "The Slave Relay Log".

- `--relay-log=file_name`

Command-Line Format	`--relay-log=file_name`	
System Variable	**Name**	`relay_log`
	Variable Scope	Global
	Dynamic Variable	No

Permitted Values	Type	`file name`

The base name for the relay log. The default base name is `host_name-relay-bin`. The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, "Specifying Program Options".

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.

- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.

- To increase speed by using load-balancing between disks.

- `--relay-log-index=file_name`

Command-Line Format	`--relay-log-index=file_name`	
System Variable	Name	`relay_log_index`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	`file name`

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, "Specifying Program Options".

If you specify this option, the value specified is also used as the base name for the relay logs. You can override this behavior by specifying a different relay log file base name using the `--relay-log` option.

- `--relay-log-info-file=file_name`

Command-Line Format	`--relay-log-info-file=file_name`

Permitted Values	Type	`file name`
	Default	`relay-log.info`

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see Section 16.2.2.2, "Slave Status Logs".

- `--relay-log-purge={0|1}`

Command-Line Format	`--relay_log_purge`	
System Variable	Name	`relay_log_purge`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	`boolean`
	Default	`TRUE`

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-space-limit=size`

Command-Line Format	`--relay_log_space_limit=#`	
System Variable	Name	`relay_log_space_limit`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values (32-bit platforms)	Type	`integer`
	Default	`0`
	Min Value	`0`
	Max Value	`4294967295`
Permitted Values (64-bit platforms)	Type	`integer`
	Default	`0`
	Min Value	`0`
	Max Value	`18446744073709547520`

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means "no limit." This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread

exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

Command-Line Format	`--replicate-do-db=name`	
Permitted Values	**Type**	`string`

The effects of this option depend on whether statement-based or row-based replication is in use.

Statement-based replication.   Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is *db_name*. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

> **Warning**
>
> To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this "check just the default database" behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Row-based replication.   Tells the slave SQL thread to restrict replication to database *db_name*. Only tables belonging to *db_name* are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

> **Note**
>
> This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.
>
> Beginning with MySQL 5.1.35, this option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements. (Bug #43263)

- `--replicate-ignore-db=db_name`

Command-Line Format	`--replicate-ignore-db=name`	
Permitted Values	**Type**	`string`

As with `--replicate-do-db`, the effects of this option depend on whether statement-based or row-based replication is in use.

Statement-based replication.   Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is *db_name*.

Row-based replication.   Tells the slave SQL thread not to update any tables in the database *db_name*. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

If you need cross-database updates to work, use `--replicate-wild-ignore-table=`*`db_name`*`.%` instead. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

> **Note**
>
> This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.
>
> Beginning with MySQL 5.1.35, this option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements. (Bug #43263)

- `--replicate-do-table=`*`db_name`*`.`*`tbl_name`*

Command-Line Format	`--replicate-do-table=name`	
Permitted Values	**Type**	`string`

Tells the slave SQL thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=`*`db_name`*`.`*`tbl_name`*

Command-Line Format	`--replicate-ignore-table=name`	
Permitted Values	**Type**	`string`

Tells the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use

this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

Command-Line Format	`--replicate-rewrite-db=old_name->new_name`	
Permitted Values	**Type**	`string`

Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.

2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.

3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

If you use this option on the command line and the ">" character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

Command-Line Format	`--replicate-same-server-id`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Command-Line Format	`--replicate-wild-do-table=name`	
Permitted Values	**Type**	`string`

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the "`%`" and "`_`" wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the "`_`" and "`%`" characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db`.

- `--replicate-wild-ignore-table=`*`db_name.tbl_name`*

Command-Line Format	`--replicate-wild-ignore-table=name`	
Permitted Values	**Type**	`string`

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=`*`host_name`*

Command-Line Format	`--report-host=host_name`	
System Variable (>= 5.1.24)	**Name**	`report_host`
	Variable Scope	Global

	Dynamic Variable	No
Permitted Values	**Type**	`string`

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

Command-Line Format	`--report-password=name`	
System Variable (>= 5.1.24)	**Name**	`report_password`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	**Type**	`string`

An arbitrary account password to be reported by the slave to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num`

Command-Line Format	`--report-port=#`	
System Variable (>= 5.1.24)	**Name**	`report_port`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	**Type**	`integer`
	Default	`3306`
	Min Value	`0`
	Max Value	`65535`

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

- `--report-user=user_name`

Command-Line Format	`--report-user=name`	
System Variable (>= 5.1.24)	**Name**	`report_user`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	**Type**	`string`

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--show-slave-auth-info`

Command-Line Format	`--show-slave-auth-info`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--skip-slave-start`

Command-Line Format	`--skip-slave-start`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

Command-Line Format	`--slave_compressed_protocol`	
System Variable	**Name**	`slave_compressed_protocol`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`boolean`
	Default	`OFF`

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=dir_name`

Command-Line Format	`--slave-load-tmpdir=dir_name`	
System Variable	**Name**	`slave_load_tmpdir`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	**Type**	`directory name`
	Default	`/tmp`

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

Command-Line Format	`--slave-net-timeout=#`	
System Variable	**Name**	`slave_net_timeout`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`integer`
	Default	`3600`
	Min Value	`1`

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement or `--master-connect-retry` option, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1,err_code2,...|all]`

(MySQL Cluster NDB 7.0.33 and later; MySQL Cluster NDB 7.1.22 and later:) `--slave-skip-errors=[err_code1,err_code2,...|all|ddl_exist_errors]`

Command-Line Format	`--slave-skip-errors=name`	
System Variable	**Name**	`slave_skip_errors`

		Variable Scope	Global
		Dynamic Variable	No
Permitted Values (<= 5.1.61-ndb-7.0.32)	Type	`string`	
	Default	`OFF`	
	Valid Values	`OFF`	
		`[list of error codes]`	
		`all`	
Permitted Values (>= 5.1.61-ndb-7.0.33)	Type	`string`	
	Default	`OFF`	
	Valid Values	`OFF`	
		`[list of error codes]`	
		`all`	
		`ddl_exist_errors`	
Permitted Values (>= 5.1.39-ndb-7.1.0, <= 5.1.61-ndb-7.1.21)	Type	`string`	
	Default	`OFF`	
	Valid Values	`OFF`	
		`[list of error codes]`	
		`all`	
Permitted Values (>= 5.1.61-ndb-7.1.22)	Type	`string`	
	Default	`OFF`	
	Valid Values	`OFF`	
		`[list of error codes]`	
		`all`	
		`ddl_exist_errors`	

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

Note

Prior to MySQL 5.1.35, this option had no effect with row-based logging. (Bug #39393)

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, *Errors, Error Codes, and Common Problems*, lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned*.

For MySQL Cluster Replication in MySQL Cluster NDB 7.0 beginning with version 7.0.33 and MySQL Cluster NDB 7.1 beginning with version 7.1.22, an additional shorthand value `ddl_exist_errors` is supported for use with the enhanced failover mechanism which is implemented in that and later version of MySQL Cluster NDB 7.2. This value is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`. *This value is not supported by the `mysqld` binary included with the MySQL Server 5.1 distribution*. (Bug #11762277, Bug #54854) For more information, see Section 17.6.8, "Implementing Failover with MySQL Cluster Replication".

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

Command-Line Format	`--init-slave=name`	
System Variable	**Name**	`init_slave`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`string`

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

> **Note**
>
> The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See Section 13.4.2.7, "START SLAVE Syntax", for more information.

- `relay_log`

Command-Line Format	`--relay-log=file_name`	
System Variable	**Name**	`relay_log`
	Variable Scope	Global

	Dynamic Variable	No
Permitted Values	**Type**	`file name`

The name of the relay log file.

- `relay_log_index`

Command-Line Format	`--relay-log-index`	
System Variable	**Name**	`relay_log_index`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	**Type**	`file name`
	Default	`*host_name*-relay-bin.index`

The name of the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `relay_log_info_file`

Command-Line Format	`--relay-log-info-file=file_name`	
System Variable	**Name**	`relay_log_info_file`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	**Type**	`file name`
	Default	`relay-log.info`

The name of the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `rpl_recovery_rank`

This variable is unused, and is removed in MySQL 5.6.

- `slave_compressed_protocol`

Command-Line Format	`--slave_compressed_protocol`	
System Variable	**Name**	`slave_compressed_protocol`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`boolean`
	Default	`OFF` 1814

Whether to use compression of the slave/master protocol if both the slave and the master support it.

- `slave_exec_mode`

Introduced	5.1.24	
Command-Line Format	`--slave-exec-mode=mode`	
System Variable	**Name**	`slave_exec_mode`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`enumeration`
	Default	`STRICT` (ALL)
	Default	`IDEMPOTENT` (NDB)
	Valid Values	`IDEMPOTENT`
		`STRICT`

Controls whether `IDEMPOTENT` or `STRICT` mode is used in replication conflict resolution and error checking. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors.

This mode is needed for multi-master replication, circular replication, and some other special replication scenarios for MySQL Cluster Replication. (See Section 17.6.10, "MySQL Cluster Replication: Multi-Master and Circular Replication", and Section 17.6.11, "MySQL Cluster Replication Conflict Resolution", for more information.) The `mysqld` supplied with MySQL Cluster ignores any value explicitly set for `slave_exec_mode`, and always treats it as `IDEMPOTENT`.

In MySQL Server 5.1, `STRICT` mode is the default value. This should not be changed; currently, `IDEMPOTENT` mode is supported only by `NDB`.

- `slave_max_allowed_packet`

Introduced	5.1.64	
System Variable	**Name**	`slave_max_allowed_packet`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`integer`
	Default	`1073741824`
	Min Value	`1024`
	Max Value	`1073741824`

In MySQL 5.1.64 and later, this variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- `slave_load_tmpdir`

Command-Line Format	`--slave-load-tmpdir=dir_name`	
System Variable	Name	`slave_load_tmpdir`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	`directory name`
	Default	`/tmp`

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- `slave_net_timeout`

Command-Line Format	`--slave-net-timeout=#`	
System Variable	Name	`slave_net_timeout`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	`integer`
	Default	`3600`
	Min Value	`1`

The number of seconds to wait for more data from a master/slave connection before aborting the read. Before MySQL 5.1.41, this timeout applies only to TCP/IP connections, not to connections made through Unix socket files, named pipes, or shared memory.

- `slave_skip_errors`

Command-Line Format	`--slave-skip-errors=name`	
System Variable	Name	`slave_skip_errors`
	Variable Scope	Global
	Dynamic Variable	No

Permitted Values (<= 5.1.61-ndb-7.0.32)	Type	`string`
	Default	`OFF`
	Valid Values	`OFF`
		`[list of error codes]`
		`all`
Permitted Values (>= 5.1.61-ndb-7.0.33)	Type	`string`
	Default	`OFF`
	Valid Values	`OFF`
		`[list of error codes]`
		`all`
		`ddl_exist_errors`
Permitted Values (>= 5.1.39-ndb-7.1.0, <= 5.1.61-ndb-7.1.21)	Type	`string`
	Default	`OFF`
	Valid Values	`OFF`
		`[list of error codes]`
		`all`
Permitted Values (>= 5.1.61-ndb-7.1.22)	Type	`string`
	Default	`OFF`
	Valid Values	`OFF`
		`[list of error codes]`
		`all`
		`ddl_exist_errors`

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `slave_transaction_retries`

Command-Line Format	`--slave_transaction_retries=#`
System Variable	Name	`slave_transaction_retries`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	`integer`
	Default	`10`
	Min Value	`0`
	Max Value	`4294967295`
Permitted Values (64-bit platforms)	Type	`integer`

Default	10
Min Value	0
Max Value	18446744073709547520

If a replication slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because the transaction's execution time exceeded `InnoDB`'s `innodb_lock_wait_timeout` or `NDBCLUSTER`'s `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default value is 10.

- `slave_type_conversions`

Introduced	5.1.44-ndb-7.1.3	
Command-Line Format	`--slave_type_conversions=set`	
System Variable	Name	`slave_type_conversions`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	`set`
	Default	
	Valid Values	`ALL_LOSSY`
		`ALL_NON_LOSSY`

Controls the type conversion mode in effect on the slave when using MySQL Cluster Replication. Its value is a comma-delimited set of zero or more elements from the list: `ALL_LOSSY`, `ALL_NON_LOSSY`. Set this variable to an empty string to disallow type conversions between the master and the slave. Changes require a restart of the slave to take effect.

For additional information on type conversion modes applicable to MySQL Cluster replication attribute promotion and demotion, see Attribute promotion and demotion (MySQL Cluster).

This variable was added in MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3.

- `sql_slave_skip_counter`

System Variable	Name	`sql_slave_skip_counter`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	`integer`

The number of events from the master that a slave server should skip.

> **Important**
>
> If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see Section 13.4.2.6, "SET GLOBAL sql_slave_skip_counter Syntax".

16.1.3.4 Binary Log Options and Variables

Startup Options Used with Binary Logging

System Variables Used with Binary Logging

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see Section 5.4.4, "The Binary Log". For additional information about using MySQL server options and system variables, see Section 5.1.3, "Server Command Options", and Section 5.1.4, "Server System Variables".

Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

Introduced	5.1.5	
Command-Line Format	`--binlog-row-event-max-size=#`	
Permitted Values (32-bit platforms)	**Type**	`integer`
	Default	`1024`
	Min Value	`256`
	Max Value	`4294967295`
Permitted Values (64-bit platforms)	**Type**	`integer`
	Default	`1024`
	Min Value	`256`
	Max Value	`18446744073709547520`

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 1024. See Section 16.1.2, "Replication Formats". This option was added in MySQL 5.1.5.

- `--log-bin[=base_name]`

Command-Line Format	`--log-bin`	
System Variable	**Name**	`log_bin`

	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	`file name`

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See Section 5.4.4, "The Binary Log".

The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see Section B.5.7, "Known Issues in MySQL", for the reason). Otherwise, MySQL uses *host_name-bin* as the base name.

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the base name. This is a known issue; see Bug #19614 for more information.

- `--log-bin-index[=file_name]`

Command-Line Format	`--log-bin-index=file_name`
Permitted Values	Type	`file name`

The index file for binary log file names. See Section 5.4.4, "The Binary Log". If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses *host_name-bin.index* as the file name.

- `--log-bin-trust-function-creators[={0|1}]`

Command-Line Format	`--log-bin-trust-function-creators`	
System Variable	Name	`log_bin_trust_function_creators`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	`boolean`
	Default	`FALSE`

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See Section 19.7, "Binary Logging of Stored Programs".

> **Note**
>
> Previously, this option was known as `--log-bin-trust-routine-creators`, which is now deprecated.

- `--log-bin-use-v1-row-events[={0|1}]`

Introduced	5.1.56-ndb-7.1.16
Command-Line Format	`--log-bin-use-v1-row-events[={0|1}]`
System Variable	Name	`log_bin_use_v1_row_events`

		Variable Scope	Global
		Dynamic Variable	No
Permitted Values (>= 5.1.56-ndb-7.0.27)	**Type**	`boolean`	
	Default	`1`	
Permitted Values (>= 5.1.56-ndb-7.1.16)	**Type**	`boolean`	
	Default	`1`	

Version 2 binary log row events are available beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16; however, Version 2 events cannot be read by previous MySQL Cluster releases. Setting `--log-bin-use-v1-row-events` to 0 causes `mysqld` to use Version 2 binary log events. Setting this option to 1 (the default) causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

`--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` are not compatible.

> **Note**
>
> MySQL Cluster NDB 7.2.1 and later use Version 2 binary log events by default (and so the default value for this option changes to 0 in those versions). You should keep this mind when planning upgrades for setups using MySQL Cluster Replication.

`--log-bin-use-v1-row-events` is not supported in mainline MySQL Server 5.1 releases.

For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

Statement selection options.   The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see Section 16.1.3.3, "Replication Slave Options and Variables".

- `--binlog-do-db=db_name`

Command-Line Format	`--binlog-do-db=name`	
Permitted Values	**Type**	`string`

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without

regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

Statement-based logging. Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is *db_name*. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

> **Warning**
>
> To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this "just check the default database" behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

Row-based logging. Logging is restricted to database *db_name*. Only changes to tables belonging to *db_name* are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

Command-Line Format	`--binlog-ignore-db=name`	
Permitted Values	**Type**	`string`

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

Statement-based logging.   Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is *db_name*.

Prior to MySQL 5.1.70, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when `SELECT DATABASE()` returned `NULL`). In MySQL 5.1.70 and later, when there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

Row-based format.   Tells the server not to log updates to any tables in the database *db_name*. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

Testing and debugging options.   The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

Command-Line Format	`--max-binlog-dump-events=#`	
Permitted Values	**Type**	`integer`
	Default	`0`

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

Command-Line Format	`--sporadic-binlog-dump-fail`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

This option is used internally by the MySQL test suite for replication testing and debugging.

System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section. For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.4, "Server System Variables".

- `binlog_cache_size`

Command-Line Format	`--binlog_cache_size=#`	
System Variable	**Name**	`binlog_cache_size`
	Variable Scope	Global
	Dynamic Variable	Yes

Permitted Values (32-bit platforms)	**Type**	`integer`
	Default	`32768`
	Min Value	`4096`
	Max Value	`4294967295`
Permitted Values (64-bit platforms)	**Type**	`integer`
	Default	`32768`
	Min Value	`4096`
	Max Value	`18446744073709547520`

The size of the cache to hold the SQL statements for the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large, multiple-statement transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.4.4, "The Binary Log".

- `binlog_direct_non_transactional_updates`

Introduced	5.1.44
Command-Line Format	`--binlog_direct_non_transactional_updates[=value]`
System Variable	**Name**	`binlog_direct_non_transactional_updates`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	**Type**	`boolean`
	Default	`OFF`

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

Beginning with MySQL 5.1.44, the `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

- `binlog_format`

Introduced	5.1.5	
Command-Line Format	`--binlog-format=format`	
System Variable (>= 5.1.8)	**Name**	`binlog_format`
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values (>= 5.1.5, <= 5.1.7)	**Type**	`enumeration`
	Default	`STATEMENT`
	Valid Values	`ROW`
		`STATEMENT`
Permitted Values (>= 5.1.8, <= 5.1.11)	**Type**	`enumeration`
	Default	`STATEMENT`
	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`
Permitted Values (>= 5.1.12, <= 5.1.28)	**Type**	`enumeration`
	Default	`MIXED`
	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`
Permitted Values (>= 5.1.29)	**Type**	`enumeration`
	Default	`STATEMENT`
	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`
Permitted Values (>= 5.1.14-ndb-6.1.0, <= 5.1.15-ndb-6.1.23)	**Type**	`enumeration`
	Default	`MIXED`
	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`

Permitted Values (>= 5.1.16-ndb-6.2.0, <= 5.1.34-ndb-6.2.18)	Type	`enumeration`
	Default	`MIXED`
	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`
Permitted Values (>= 5.1.19-ndb-6.3.0, <= 5.1.73-ndb-6.3.54)	Type	`enumeration`
	Default	`MIXED`
	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`
Permitted Values (>= 5.1.32-ndb-7.0.4, <= 5.1.73-ndb-7.0.42)	Type	`enumeration`
	Default	`MIXED`
	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`
Permitted Values (>= 5.1.39-ndb-7.1.0, <= 5.1.51-ndb-7.2.0)	Type	`enumeration`
	Default	`MIXED`
	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See Section 16.1.2, "Replication Formats". `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

> **Note**
>
> While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's `binlog_format` setting; a given MySQL Server can change only its own logging format.

The startup variable was added in MySQL 5.1.5, and the runtime variable in MySQL 5.1.8. `MIXED` was added in MySQL 5.1.8.

`STATEMENT` was used by default prior to MySQL 5.1.12; in MySQL 5.1.12, the default was changed to `MIXED`. In MySQL 5.1.29, the default was changed back to `STATEMENT`.

You must have the `SUPER` privilege to set the global `binlog_format` value. Starting with MySQL 5.1.29, you must have the `SUPER` privilege to set either the global or session `binlog_format` value. (Bug #39106)

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see Section 13.7.4.1, "SET Syntax for Variable Assignment".

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.

- If the `NDBCLUSTER` storage engine is enabled.

- If the session is currently in row-based replication mode and has open temporary tables.

Trying to switch the format in those cases results in an error.

Before MySQL 5.1.8, switching to row-based replication format would implicitly set `--log-bin-trust-function-creators=1` and `--innodb_locks_unsafe_for_binlog`. This does not occur for MySQL 5.1.8 and later.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`

- `--replicate-ignore-db`

- `--binlog-do-db`

- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `log_bin`

System Variable	Name	`log_bin`
	Variable Scope	Global
	Dynamic Variable	No

Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is `ON`; otherwise it is `OFF`. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

See Section 5.4.4, "The Binary Log".

- `log_bin_use_v1_row_events`

Introduced	5.1.56-ndb-7.1.16
Command-Line Format	`--log-bin-use-v1-row-events[={0|1}]`
System Variable	**Name**	`log_bin_use_v1_row_events`
	Variable Scope	Global

	Dynamic Variable	No
Permitted Values (>= 5.1.56-ndb-7.0.27)	**Type**	`boolean`
	Default	`1`
Permitted Values (>= 5.1.56-ndb-7.1.16)	**Type**	`boolean`
	Default	`1`

Shows whether Version 2 binary logging, available beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

Other than when performing upgrades of MySQL Cluster Replication, `--log-bin-use-v1-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` are not compatible.

> **Note**
>
> MySQL Cluster NDB 7.2.1 and later use Version 2 binary log row events by default (and so the default value for this variable changes to 0 in those versions). You should keep this mind when planning upgrades for setups using MySQL Cluster Replication.

This variable is not supported in mainline MySQL Server 5.1.

For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `log_slave_updates`

Command-Line Format	`--log-slave-updates`	
System Variable	**Name**	`log_slave_updates`
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See Section 16.1.3, "Replication and Binary Logging Options and Variables".

- `max_binlog_cache_size`

Command-Line Format	`--max_binlog_cache_size=#`	
System Variable	**Name**	`max_binlog_cache_size`

	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (>= 5.1.36)	**Type**	`integer`
	Default	`18446744073709547520`
	Min Value	`4096`
	Max Value	`18446744073709547520`
Permitted Values (32-bit platforms, <= 5.1.35)	**Type**	`integer`
	Default	`4294967295`
	Min Value	`4096`
	Max Value	`4294967295`
Permitted Values (64-bit platforms, <= 5.1.35)	**Type**	`integer`
	Default	`18446744073709547520`
	Min Value	`4096`
	Max Value	`18446744073709547520`

If a multiple-statement transaction requires more than this many bytes of memory, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms. As of MySQL 5.1.36, the maximum value is 16EB (exabytes) on all platforms. The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

In MySQL 5.1, a change in `max_binlog_cache_size` takes immediate effect for all active sessions.

- `max_binlog_size`

Command-Line Format	`--max_binlog_size=#`	
System Variable	**Name**	`max_binlog_size`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`integer`
	Default	`1073741824`
	Min Value	`4096`
	Max Value	`1073741824`

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `sync_binlog`

Command-Line Format	`--sync-binlog=#`	
System Variable	**Name**	`sync_binlog`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	**Type**	`integer`
	Default	`0`
	Min Value	`0`
	Max Value	`4294967295`
Permitted Values (64-bit platforms)	**Type**	`integer`
	Default	`0`
	Min Value	`0`
	Max Value	`18446744073709547520`

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from time to time as for any other file. A value of 1 is the safest choice because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

16.1.4 Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

16.1.4.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
               Slave_IO_State: Waiting for master to send event
                  Master_Host: master1
                  Master_User: root
                  Master_Port: 3306
                Connect_Retry: 60
              Master_Log_File: mysql-bin.000004
          Read_Master_Log_Pos: 931
               Relay_Log_File: slave1-relay-bin.000056
                Relay_Log_Pos: 950
        Relay_Master_Log_File: mysql-bin.000004
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
                   Last_Errno: 0
                   Last_Error:
                 Skip_Counter: 0
          Exec_Master_Log_Pos: 931
              Relay_Log_Space: 1365
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Master_SSL_Allowed: No
           Master_SSL_CA_File:
           Master_SSL_CA_Path:
              Master_SSL_Cert:
            Master_SSL_Cipher:
               Master_SSL_Key:
        Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
                Last_IO_Errno: 0
                Last_IO_Error:
               Last_SQL_Errno: 0
               Last_SQL_Error:
```

The key fields from the status report to examine are:

- `Slave_IO_State`: The current status of the slave. See Section 8.14.6, "Replication Slave I/O Thread States", and Section 8.14.7, "Replication Slave SQL Thread States", for more information.

- `Slave_IO_Running`: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be `Yes` unless you have not yet started replication or have explicitly stopped it with `STOP SLAVE`.

- `Slave_SQL_Running`: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be `Yes`.

- `Last_IO_Error`, `Last_SQL_Error`: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.

- `Seconds_Behind_Master`: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

  A value of 0 for `Seconds_Behind_Master` can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can

occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, `slave_net_timeout` has not yet elapsed.

It is also possible that transient values for `Seconds_Behind_Master` may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, `Seconds_Behind_Master` displays 0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (`Master_Log_file`, `Read_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.

- (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.

- (`Relay_Log_File`, `Relay_Log_Pos`): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```
mysql> SHOW PROCESSLIST \G;
*************************** 4. row ***************************
     Id: 10
   User: root
   Host: slave1:58371
     db: NULL
Command: Binlog Dump
   Time: 777
  State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----------+--------+------+-------------------+-----------+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----------+--------+------+-------------------+-----------+
|        10 | slave1 | 3306 |                 0 |         1 |
+-----------+--------+------+-------------------+-----------+
1 row in set (0.00 sec)
```

16.1.4.2 Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the START SLAVE statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

16.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, SELECT statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see Section 16.2.1, "Replication Implementation Details".

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See Section 8.14, "Examining Thread Information", for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See Section 16.2.2, "Replication Relay and Status Logs".

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

16.2.1 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.**   The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

  The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.**   When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

  The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

  The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- **Slave SQL thread.**   The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see Section 8.14.5, "Replication Master Thread States". For slave states, see Section 8.14.6, "Replication Slave I/O Thread States", and Section 8.14.7, "Replication Slave SQL Thread States".

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from SHOW PROCESSLIST looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 2
   User: root
   Host: localhost:32931
     db: NULL
Command: Binlog Dump
   Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
         be updated
   Info: NULL
```

Here, thread 2 is a Binlog Dump replication thread that services a connected slave. The State information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no Binlog Dump threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from SHOW PROCESSLIST looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 10
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 11
  State: Waiting for master to send event
   Info: NULL
*************************** 2. row ***************************
     Id: 11
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 11
  State: Has read all relay log; waiting for the slave I/O
         thread to update it
   Info: NULL
```

The State information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that SHOW PROCESSLIST was run, both threads were idle, waiting for further updates.

The value in the Time column can show how late the slave is compared to the master. See Section A.13, "MySQL 5.1 FAQ: Replication". If sufficient time elapses on the master side without activity on the Binlog Dump thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of net_write_timeout and net_retry_count; for more information about these, see Section 5.1.4, "Server System Variables".

The SHOW SLAVE STATUS statement provides additional information about replication processing on a slave server. See Section 16.1.4.1, "Checking Replication Status".

16.2.2 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.

- The *master info log* contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.

- The *relay log info log* holds status information about the execution point within the slave's relay log.

16.2.2.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term "relay log file" generally denotes an individual numbered file containing database events. The term "relay log" collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see Section 4.6.7, "`mysqlbinlog` — Utility for Processing Binary Log Files").

By default, relay log file names have the form *host_name*-relay-bin.*nnnnnn* in the data directory, where *host_name* is the name of the slave server host and *nnnnnn* is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is *host_name-relay-bin.index* in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see Section 16.1.3, "Replication and Binary Logging Options and Variables").

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.

- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.

- When the size of the current relay log file becomes "too large," determined as follows:

  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.

- If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

16.2.2.2 Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. See Section 16.1.3, "Replication and Binary Logging Options and Variables".

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 13.4.2, "SQL Statements for Controlling Slave Servers". Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log should be protected because it contains the password for connecting to the master. See Section 6.1.2.3, "Passwords and Logging".

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file and the columns displayed by `SHOW SLAVE STATUS`.

Line in `master.info`	`SHOW SLAVE STATUS` Column	Description
1		Number of lines in the file
2	`Master_Log_File`	The name of the master binary log currently being read from the master
3	`Read_Master_Log_Pos`	The current position within the master binary log that have been read from the master
4	`Master_Host`	The host name of the master
5	`Master_User`	The user name used to connect to the master
6	Password (not shown by `SHOW SLAVE STATUS`)	The password used to connect to the master
7	`Master_Port`	The network port used to connect to the master
8	`Connect_Retry`	The period (in seconds) that the slave will wait before trying to reconnect to the master
9	`Master_SSL_Allowed`	Indicates whether the server supports SSL connections
10	`Master_SSL_CA_File`	The file used for the Certificate Authority (CA) certificate
11	`Master_SSL_CA_Path`	The path to the Certificate Authority (CA) certificates
12	`Master_SSL_Cert`	The name of the SSL certificate file

Line in `master.info`	`SHOW SLAVE STATUS` Column	Description
13	`Master_SSL_Cipher`	The list of possible ciphers used in the handshake for the SSL connection
14	`Master_SSL_Key`	The name of the SSL key file
15	`Master_SSL_Verify_Server_Cert`	Whether to verify the server certificate (added in MySQL 5.1.18)

The slave SQL thread updates the relay log info log. The following table shows the correspondence between the lines in the `relay-log.info` file and the columns displayed by `SHOW SLAVE STATUS`.

Line in `relay-log.info`	`SHOW SLAVE STATUS` Column	Description
1	`Relay_Log_File`	The name of the current relay log file
2	`Relay_Log_Pos`	The current position within the relay log file; events up to this position have been executed on the slave database
3	`Relay_Master_Log_File`	The name of the master binary log file from which the events in the relay log file were read
4	`Exec_Master_Log_Pos`	The equivalent position within the master's binary log file of events that have already been executed

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

When you back up the slave's data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

16.2.3 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see Section 16.2.3.1, "Evaluation of Database-Level Replication and Binary Logging Options". You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See Section 16.1.3, "Replication and Binary Logging Options and Variables".)

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see Section 16.2.3.1, "Evaluation of Database-Level Replication and Binary Logging Options", for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see Section 16.2.3.2, "Evaluation of Table-Level Replication Options", for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

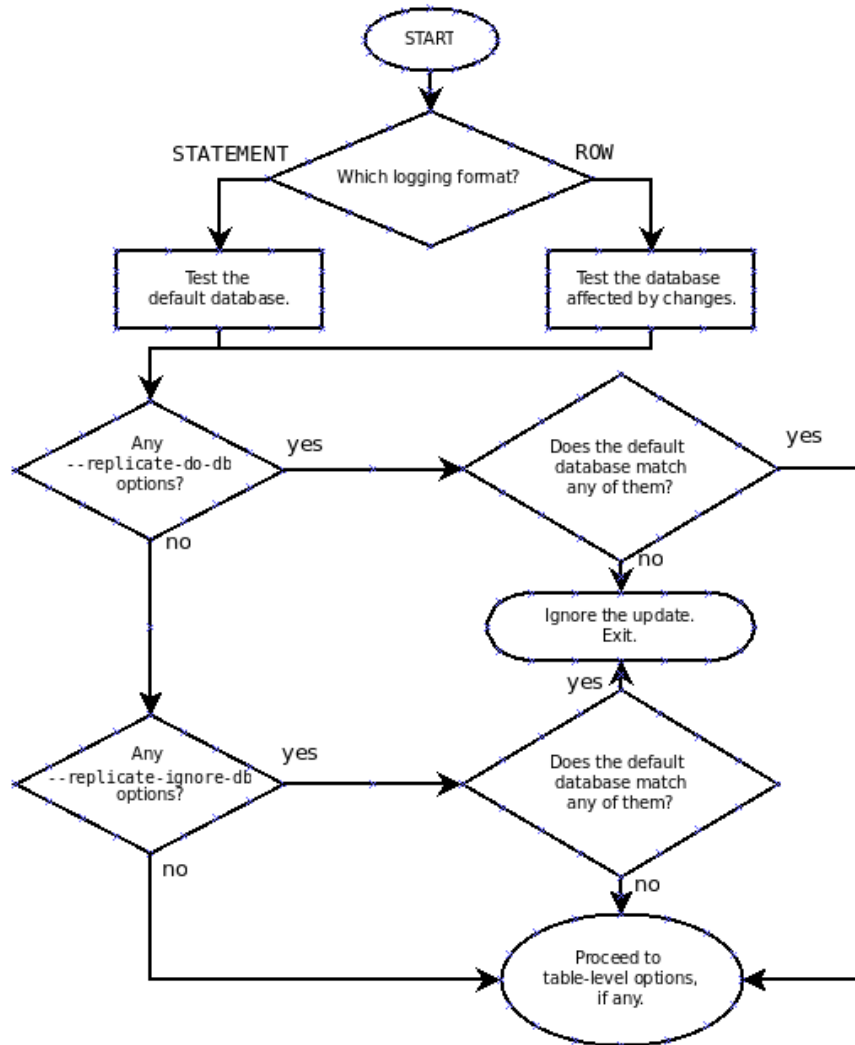
To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing "do" and "ignore" options, or wildcard and nonwildcard options. An example of the latter that may have unintended effects is the use of `--replicate-do-db` and `--replicate-wild-do-table` together, where `--replicate-wild-do-table` uses a pattern for the database name that matches the name given for `--replicate-do-db`. Suppose a replication slave is started with `--replicate-do-db=dbx` `--replicate-wild-do-table=db%.t1`. Then, suppose that on the master, you issue the statement `CREATE DATABASE dbx`. Although you might expect it, this statement is not replicated because it does not reference a table named `t1`.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

> **Note**
>
> Database-level filtering options are case-sensitive on platforms supporting case sensitivity in filenames, whereas table-level filtering options are not (regardless of platform). This is true regardless of the value of the `lower_case_table_names` system variable. These are known issues which are fixed in MySQL 5.5.

16.2.3.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.


The steps involved are listed here:

1. Are there any `--replicate-do-db` options?

    *   **Yes.**   Do any of them match the database?

        *   **Yes.**   Execute the statement and exit.

        *   **No.**   Ignore the statement and exit.

    *   **No.**   Continue to step 2.

2. Are there any `--replicate-ignore-db` options?

    *   **Yes.**   Do any of them match the database?

        *   **Yes.**   Ignore the statement and exit.

        *   **No.**   Continue to step 3.

    *   **No.**   Continue to step 3.

3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Section 16.2.3.2, "Evaluation of Table-Level Replication Options".

> **Important**
>
> A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?

   - **Yes.** Continue to step 2.

   - **No.** Log the statement and exit.

2. Is there a default database (has any database been selected by `USE`)?

   - **Yes.** Continue to step 3.

   - **No.** Ignore the statement and exit.

3. There is a default database. Are there any `--binlog-do-db` options?

   - **Yes.** Do any of them match the database?

     - **Yes.** Log the statement and exit.

     - **No.** Ignore the statement and exit.

   - **No.** Continue to step 4.

4. Do any of the `--binlog-ignore-db` options match the database?

   - **Yes.** Ignore the statement and exit.

   - **No.** Log the statement and exit.

> **Important**
>
> For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created, altered, or dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean "ignore other databases". For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

16.2.3.2 Evaluation of Table-Level Replication Options

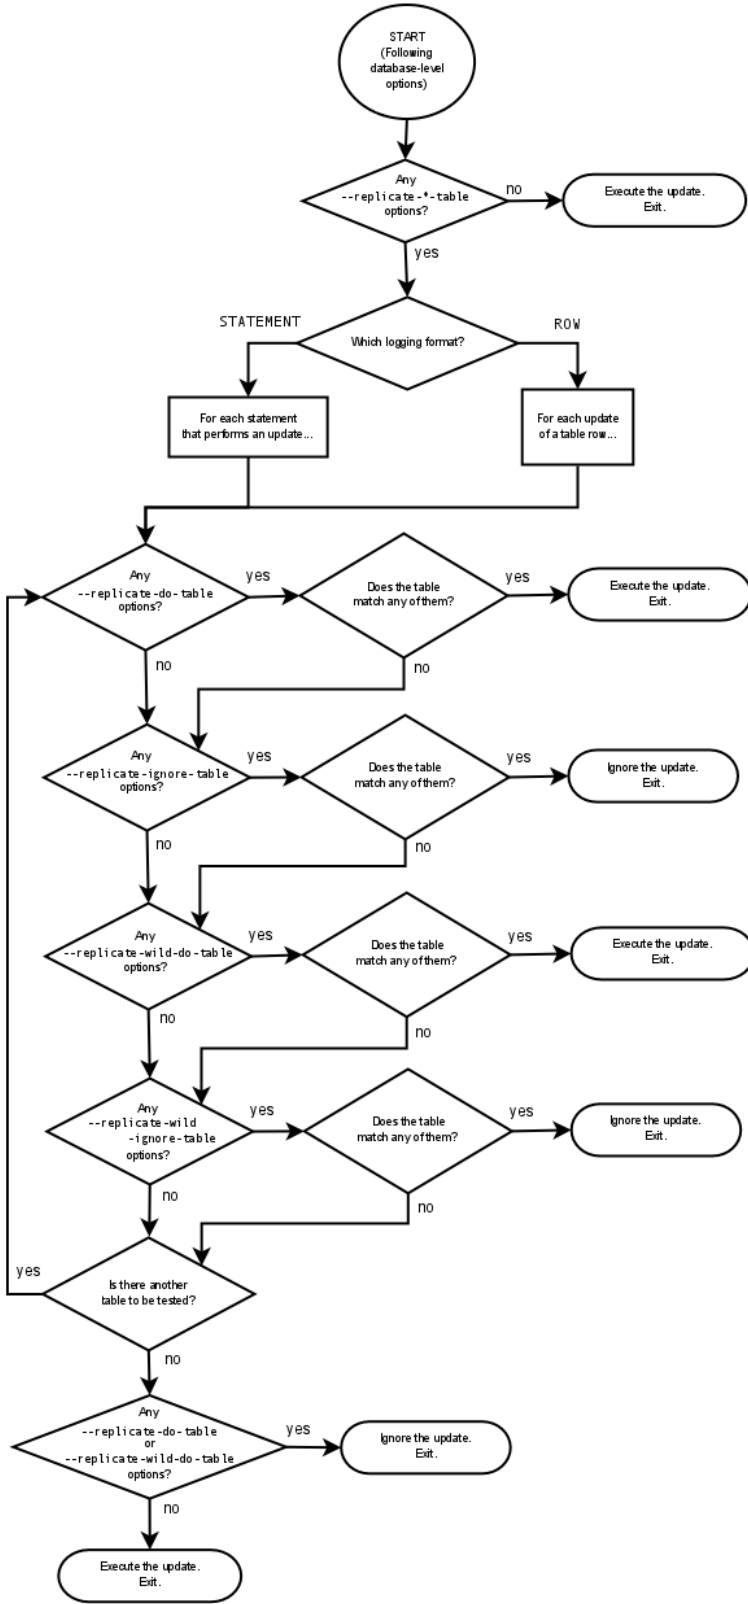
The slave checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.

- One or more database options were found, and were evaluated to arrive at an "execute" condition according to the rules described in the previous section (see Section 16.2.3.1, "Evaluation of Database-Level Replication and Binary Logging Options").

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

> **Note**
>
> For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.


The following steps describe this evaluation in more detail:

1. Are there any table options?

   - **Yes.**   Continue to step 2.

   - **No.**   Execute the event and exit.

2. Are there any `--replicate-do-table` options?

   - **Yes.**   Does the table match any of them?

     - **Yes.**   Execute the event and exit.

     - **No.**   Continue to step 3.

   - **No.**   Continue to step 3.

3. Are there any `--replicate-ignore-table` options?

   - **Yes.**   Does the table match any of them?

     - **Yes.**   Ignore the event and exit.

     - **No.**   Continue to step 4.

   - **No.**   Continue to step 4.

4. Are there any `--replicate-wild-do-table` options?

   - **Yes.**   Does the table match any of them?

     - **Yes.**   Execute the event and exit.

     - **No.**   Continue to step 5.

   - **No.**   Continue to step 5.

5. Are there any `--replicate-wild-ignore-table` options?

   - **Yes.**   Does the table match any of them?

     - **Yes.**   Ignore the event and exit.

     - **No.**   Continue to step 6.

   - **No.**   Continue to step 6.

6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?

   - **Yes.**   Ignore the event and exit.

   - **No.**   Execute the event and exit.

16.2.3.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

Condition (Types of Options)	Outcome
No `--replicate-*` options at all:	The slave executes all events that it receives from the master.
`--replicate-*-db` options, but no table options:	The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.
`--replicate-*-table` options, but no database options:	All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.
A combination of database and table options:	The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

Statement-based replication.   The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, *and the `INSERT` statement is ignored.* The table options are not checked.

Row-based replication.   The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, *and the row is inserted.*

16.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see Section 16.3.1, "Using Replication for Backups".

For advice and tips on using different storage engines on the master and slaves, see Section 16.3.2, "Using Replication with Different Master and Slave Storage Engines".

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See Section 16.3.3, "Using Replication for Scale-Out".

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See Section 16.3.4, "Replicating Different Databases to Different Slaves"

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see Section 16.3.5, "Improving Replication Performance".

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see Section 16.3.6, "Switching Masters During Failover".

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see Section 16.3.7, "Setting Up Replication to Use Secure Connections".

16.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of "live" data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See Section 16.3.1.1, "Backing Up a Slave Using mysqldump".

- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see Section 16.3.1.2, "Backing Up Raw Data from a Slave".

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See Section 16.3.1.3, "Backing Up a Master or Slave by Making It Read Only".

16.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see Section 4.5.4, "`mysqldump` — A Database Backup Program"). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See Section 16.1.4.1, "Checking Replication Status". If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see Section 16.3.4, "Replicating Different Databases to Different Slaves".

16.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as `InnoDB`. With `InnoDB`, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition

to the slave's data, you should also back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

16.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.

2. Perform the backup.

3. Change the server back to its normal read/write state.

> **Note**
>
> The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see Section 4.5.4, "`mysqldump` — A Database Backup Program"). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.
>
> These instructions also require MySQL 5.1.15 or higher. For earlier versions, setting `read_only` does not block while table locks or outstanding transactions are pending, so data changes can still occur during the backup operation and produce inconsistent backup results.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

• A master server M1

• A slave server S1 that has M1 as its master

• A client C1 connected to M1

• A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.

- Requests for query results sent by C1 to M1 will succeed.

- Making a backup on M1 is safe.

- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.

- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

16.3.2 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the system variables `storage_engine` and `table_type` are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Section 16.3.3, "Using Replication for Scale-Out"), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

  Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-innodb` option on your slave to disable the `InnoDB` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.

- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

   ```
   mysql> STOP SLAVE;
   ```

   This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.

3. Start the slave replication process again:

   ```
   mysql> START SLAVE;
   ```

Although the `storage_engine` and `table_type` variables are not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

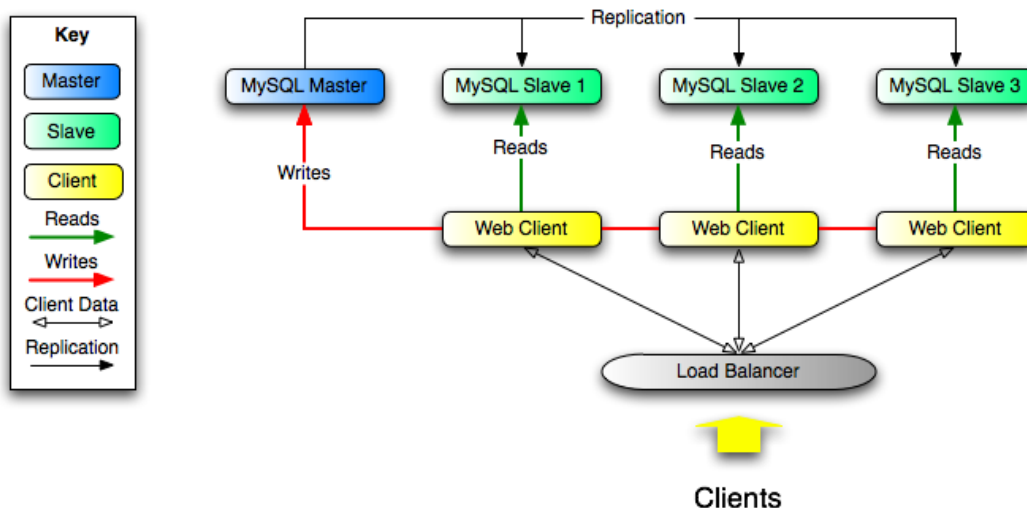
When replicated, the `storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

16.3.3 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in Figure 16.1, "Using Replication to Improve Performance During Scale-Out".

Figure 16.1 Using Replication to Improve Performance During Scale-Out


If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity

and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`

- `safe_reader_connect()`

- `safe_reader_statement()`

- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

16.3.4 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 16.2, "Using Replication to Replicate Databases to Separate Replication Slaves".

Figure 16.2 Using Replication to Replicate Databases to Separate Replication Slaves
You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

> ⚠️ **Important**
>
> You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

> However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 16.2, "Using Replication to Replicate Databases to Separate Replication Slaves", you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.

- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.

- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.

- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.

- Use a raw data file dump and include only the specific files and databases that you need for each slave.

> **Note**
>
> This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

16.3.5 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in Figure 16.3, "Using an Additional Replication Host to Improve Performance".

Figure 16.3 Using an Additional Replication Host to Improve Performance
For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.

- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.

- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.

- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See Section 16.3.4, "Replicating Different Databases to Different Slaves".

- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See Section 16.3.2, "Using Replication with Different Master and Slave Storage Engines".

- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents "dumb" slaves from also logging events they have executed into their own binary log.

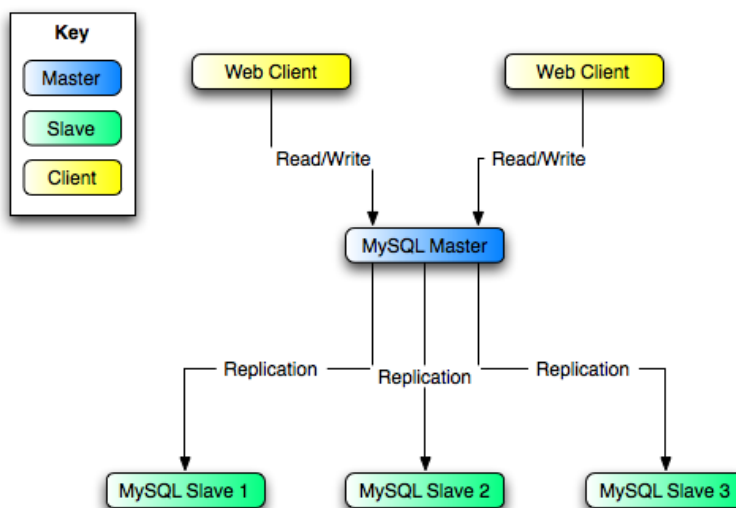
16.3.6 Switching Masters During Failover

There is in MySQL 5.1 no official solution for providing failover between master and slaves in the event of a failure. Instead, you must set up a master and one or more slaves; then, you need to write an application or script that monitors the master to check whether it is up, and instructs the slaves and applications to change master in case of failure. This section discusses some of the issues encountered when setting up failover in this fashion.

> **Note**
>
> The MySQL Utilities include a `mysqlfailover` tool that provides failover capability using GTIDs, support for which requires MySQL 5.6 or later. For more information, see `mysqlfailover` — Automatic replication health monitoring and failover, and Replication with Global Transaction Identifiers.

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in Figure 16.4, "Redundancy Using Replication, Initial Structure".

Figure 16.4 Redundancy Using Replication, Initial Structure


In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 16.3.3, "Using Replication for Scale-Out".

Each MySQL Slave (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which writes the updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, it writes any updates that it receives from `Master` in its own binary log. This

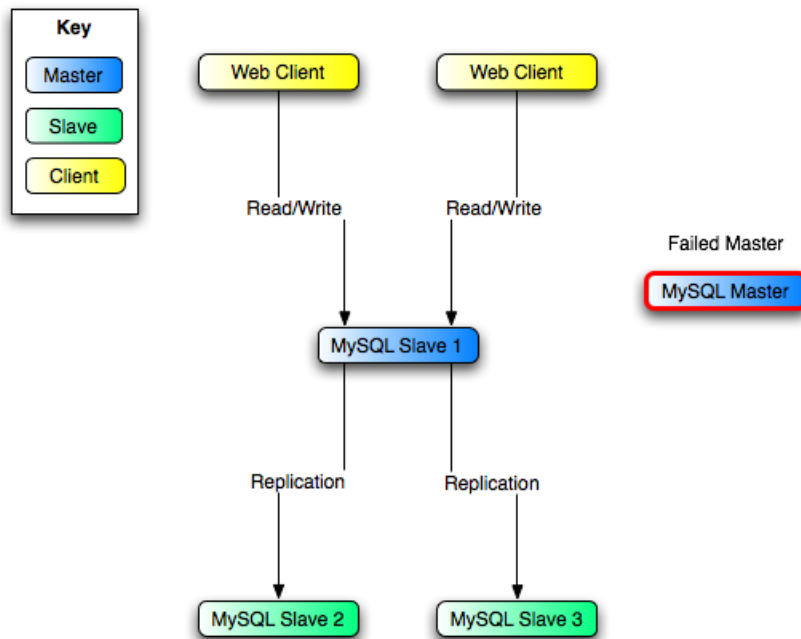
means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in Figure 16.5, "Redundancy Using Replication, After Master Failure".

Figure 16.5 Redundancy Using Replication, After Master Failure


When `Master` becomes available again, you should make it a slave of `Slave 1`. To do this, issue on `Master` the same `CHANGE MASTER TO` statement as that issued on `Slave 2` and `Slave 3` previously. `Master` then becomes a slave of `Slave 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Master` a master again, use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. If you fail to do this, the slaves may

pick up stale writes from the `Web Client` applications dating from before the point at which `Master` became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

16.3.7 Setting Up Replication to Use Secure Connections

To use a secure connection for encrypting the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support secure connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up secure connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for secure connections, see Section 6.4.4, "Configuring MySQL to Use Secure Connections".

To enable secure connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.

- `ssl-cert` identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.

- `ssl-key` identifies the server private key.

On the slave, there are two ways to specify the information required for connecting securely to the master. You can either name the slave certificate and key files in the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify that information using the `CHANGE MASTER TO` statement:

- To name the slave certificate and key files using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file, changing the file names as necessary:

  ```
  [client]
  ssl-ca=cacert.pem
  ssl-cert=client-cert.pem
  ssl-key=client-key.pem
  ```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to connect securely:

```
mysql> CHANGE MASTER TO
    -> MASTER_HOST='master_hostname',
    -> MASTER_USER='replicate',
    -> MASTER_PASSWORD='password',
    -> MASTER_SSL=1;
```

- To specify the certificate and key names using the `CHANGE MASTER TO` statement, append the appropriate `MASTER_SSL_xxx` options:

```
mysql> CHANGE MASTER TO
    -> MASTER_HOST='master_hostname',
    -> MASTER_USER='replicate',
    -> MASTER_PASSWORD='password',
    -> MASTER_SSL=1,
    -> MASTER_SSL_CA = 'ca_file_name',
    -> MASTER_SSL_CAPATH = 'ca_directory_name',
    -> MASTER_SSL_CERT = 'cert_file_name',
    -> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that a secure connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see Section 13.4.2.1, "CHANGE MASTER TO Syntax".

If you want to enforce the use of secure connections during replication, then create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE SSL` option for that user. For example:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```
mysql> GRANT USAGE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

16.4 Replication Notes and Tips

16.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.1 (or later), you cannot replicate to a slave that uses MySQL 5.0 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.1 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see Section 19.7, "Binary Logging of Stored Programs". For more information about row-based logging and row-based replication, see Section 5.4.4.1, "Binary Logging Formats", and Section 16.1.2, "Replication Formats".

For additional information specific to replication and `InnoDB`, see Section 14.6.11, "InnoDB and MySQL Replication". For information relating to replication with MySQL Cluster, see Section 17.6, "MySQL Cluster Replication".

16.4.1.1 Replication and AUTO_INCREMENT

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- When using statement-based replication, `AUTO_INCREMENT` columns in tables on the slave must match the same columns on the master; that is, `AUTO_INCREMENT` columns must be replicated to `AUTO_INCREMENT` columns.

  This is a known issue which is fixed in MySQL 5.5. (Bug #12669186)

- Prior to MySQL 5.1.12, a stored procedure that uses `LAST_INSERT_ID()` does not replicate properly using statement-based binary logging.

- Prior to MySQL 5.1.12, when a stored routine or trigger caused an `INSERT` into an `AUTO_INCREMENT` column, the generated `AUTO_INCREMENT` value was not written into the binary log, so a different value could in some cases be inserted on the slave.

- An insert into an `AUTO_INCREMENT` column caused by a stored routine or trigger running on a master that uses MySQL 5.0.60 or earlier does not replicate correctly to a slave running MySQL 5.1.12 through 5.1.23 (inclusive). (Bug #33029)

  A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. Beginning with MySQL 5.1.40, such statements are marked as unsafe. (Bug #45677)

- The `AUTO_INCREMENT` table option was not replicated correctly prior to MySQL 5.1.31. (Bug #41986)

- An `INSERT` into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. Beginning with MySQL 5.1.64, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

  This issue does not affect tables using the `InnoDB` storage engine, since an `InnoDB` table with an AUTO_INCREMENT column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

> **Important**
>
> To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also Section B.5.6.1, "Problems with ALTER TABLE".

16.4.1.2 Replication and BLACKHOLE Tables

The `BLACKHOLE` storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped— they are not written to the binary log.

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

16.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

16.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format, which is not guaranteed to remain the same between MySQL release series.

For example, the storage format for `VARCHAR` changed between MySQL 4.1 and 5.0, so if a 4.1 table is upgraded to MySQL 5.0, the checksum value may change.

16.4.1.5 Replication of CREATE ... IF NOT EXISTS Statements

This section discusses the rules that are applied when various `CREATE ... IF NOT EXISTS` statements are replicated.

Previous to MySQL 5.1.38.   `CREATE DATABASE IF NOT EXISTS` was replicated only if the database named in the statement did not exist on the master. `CREATE TABLE IF NOT EXISTS` was replicated only if the table named in the statement did not exist on the master.

MySQL 5.1.39 and later.   Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master. Similarly, every `CREATE TABLE IF NOT EXISTS` statement is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. However, replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see Section 16.4.1.6, "Replication of CREATE TABLE ... SELECT Statements", for more information.

Replication of CREATE EVENT IF NOT EXISTS.   `CREATE EVENT IF NOT EXISTS` is always replicated, whether or not the event named in the statement already exists on the master. This is true for all MySQL 5.1 releases beginning with MySQL 5.1.6, when this statement was introduced.

See also Bug #45574.

16.4.1.6 Replication of CREATE TABLE ... SELECT Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit (Section 13.3.3, "Statements That Cause an Implicit Commit").

- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.

  - `STATEMENT` or `MIXED` format: The statement is logged as written.

  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL handles the statement in a version-dependent way.

In MySQL 5.1 before 5.1.51 and in MySQL 5.5 before 5.5.6 (this is the original behavior):

- `STATEMENT` or `MIXED` format: The statement is logged as written.

- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.1 as of 5.1.51:

- `STATEMENT` or `MIXED` format: The statement is logged as the equivalent pair of `CREATE TABLE` and `INSERT INTO ... SELECT` statements.

- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.5 as of 5.5.6:

- Nothing is inserted or logged.

These version dependencies arise due to a change in MySQL 5.5.6 in handling of `CREATE TABLE ... SELECT` not to insert rows if the destination table already exists, and a change made in MySQL 5.1.51 to preserve forward compatibility in replication of such statements from a 5.1 master to a 5.5 slave. For details, see Section 13.1.17.2, "CREATE TABLE ... SELECT Syntax".

16.4.1.7 Replication of CURRENT_USER()

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`

- `RENAME USER`

- `GRANT`

- `REVOKE`

- `CREATE FUNCTION`

- `CREATE PROCEDURE`

- `CREATE TRIGGER`

- `CREATE EVENT`

- `CREATE VIEW`

- `ALTER EVENT`

- `ALTER VIEW`

- `SET PASSWORD`

In all MySQL 5.1 releases, when `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of the statements `CREATE FUNCTION`, `CREATE PROCEDURE`, `CREATE TRIGGER`, `CREATE EVENT`, `CREATE VIEW`, or `ALTER VIEW` when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the same user on both the master and the slave when the statement is replicated. Beginning with MySQL 5.1.49, `CURRENT_USER()` or `CURRENT_USER` is also expanded prior to being written to the binary log when used in `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE`, or `ALTER EVENT`. (Bug #48321)

16.4.1.8 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 5.1, the statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are logged only when `binlog_format` is equal to `ROW`. These statements are not written to the binary log when using either the statement-based or mixed logging format.

16.4.1.9 Replication of DROP ... IF EXISTS Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

Beginning with MySQL 5.1.33, `DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master. (Bug #13684)

16.4.1.10 Replication with Differing Table Definitions on Master and Slave

Starting with MySQL 5.1.21, source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

> **Note**
>
> Replication between tables which are partitioned differently from one another is not supported. See Section 16.4.1.26, "Replication and Partitioning".

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

Replication with More Columns on Master or Slave

Starting with MySQL 5.1.21, you can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

  (This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

  This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

  Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
    c1 INT,
    c2 INT,
    c3 INT
);
```

  Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

  The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

• Each "extra" column in the version of the table having more columns must have a default value.

> **Note**
>
> A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see Section 11.6, "Data Type Default Values").

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

Examples. The following examples illustrate some valid and invalid table definitions:

More columns on the master. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave>  CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT);
```

More columns on the slave. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

> **Important**
>
> Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

Statement-based replication.   When using statement-based replication, a simple rule of thumb to follow is, "If the statement run on the master would also execute successfully on the slave, it should also replicate successfully". In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

When using statement-based replication, `AUTO_INCREMENT` columns must be the same on both the master and the slave; otherwise, updates may be applied to the wrong table on the slave. This is a known issue which is fixed in MySQL 5.5. (Bug #12669186)

> **Note**
>
> The restrictions described in the next few paragraphs do not apply to MySQL Cluster Replication, beginning with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3. These and later versions of MySQL Cluster support attribute promotion and demotion (such as `TINYINT` to `BIGINT`, and `VARCHAR(50)` to `CHAR(25)`, respectively) in replication; see Attribute promotion and demotion (MySQL Cluster), for more information.

Row-based replication.   For row-based replication, the case is not so simple, due to the fact that changes rather than statements are replicated, and these changes are transmitted from master to slave using formats that do not always map directly to MySQL server column data types. For example, with row-based binary logging, you cannot replicate between different `INT` subtypes, such as from `TINYINT` to `BIGINT`, because changes to columns of these types are represented differently from one another in the binary log when using row-based logging. However, you can replicate from `BLOB` to `TEXT` using row-based replication because changes to `BLOB` and `TEXT` columns are represented using the same format in the binary log.

Supported conversions for attribute promotion when using row-based replication are shown in the following table:

From (Master)	To (Slave)
BINARY	CHAR
BLOB	TEXT
CHAR	BINARY
DECIMAL	NUMERIC
NUMERIC	DECIMAL
TEXT	BLOB
VARBINARY	VARCHAR
VARCHAR	VARBINARY

Note

In all cases, the size or width of the column on the slave must be equal to or greater than that of the column on the master. For example, you can replicate from a `CHAR(10)` column on the master to a column that uses `BINARY(10)` or `BINARY(25)` on the slave, but you cannot replicate from a `CHAR(10)` column on the master to `BINARY(5)` column on the slave.

Any unique index (including primary keys) having a prefix must use a prefix of the same length on both master and slave; in such cases, differing prefix lengths are disallowed. It is possible to use a nonunique index whose prefix length differs between master and slave, but this can cause serious performance issues, particularly when the prefix used on the master is longer. This is due to the fact that 2 unique prefixes of a given length may no longer be unique at a shorter length; for example, the words *catalogue* and *catamount* have the 5-character prefixes *catal* and *catam*, respectively, but share the same 4-character prefix (*cata*). This can lead to queries that use such indexes executing less efficiently on the slave, when a shorter prefix is employed in the slave' definition of the same index than on the master.

For `DECIMAL` and `NUMERIC` columns, both the mantissa (*M*) and the number of decimals (*D*) must be the same size or larger on the slave as compared with the master. For example, replication from a `NUMERIC(5,4)` to a `DECIMAL(6,4)` works, but not from a `NUMERIC(5,4)` to a `DECIMAL(5,3)`.

MySQL (except for MySQL Cluster) does *not* support attribute promotion of any of the following data types to or from any other data type when using row-based replication:

• `INT` (including `TINYINT`, `SMALLINT`, `MEDIUMINT`, `BIGINT`).

Promotion between `INT` subtypes—for example, from `SMALLINT` to `BIGINT`—is also not supported.

- `SET` or `ENUM`.

- `FLOAT` or `DOUBLE`.

- All of the data types relating to dates, times, or both: `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`.

Attribute promotion and demotion (MySQL Cluster).   Beginning with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3, MySQL Cluster Replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

Lossy and non-lossy conversions.   In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a "fit" in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy* conversion.

Type conversion modes (slave_type_conversions variable).   The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

Mode	Effect
`ALL_LOSSY`	In this mode, type conversions that would mean loss of information are permitted. This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling *only* this mode permits an `INT` column to be converted to `TINYINT` (a lossy conversion), but not a `TINYINT` column to an `INT` column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.
`ALL_NON_LOSSY`	This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type. Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the `ALL_LOSSY` mode. If only `ALL_NON_LOSSY` is set, but not `ALL_LOSSY`, then attempting a conversion that would result in the loss of data (such as `INT` to `TINYINT`, or `CHAR(25)` to `VARCHAR(20)`) causes the slave to stop with an error.
`ALL_LOSSY,ALL_NON_LOSSY`	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
[*empty*]	When `slave_type_conversions` is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types. This mode is the default.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

Supported conversions.   Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

  This includes conversions between the signed and unsigned versions of these types.

  Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For insuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

  `FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where $D' >= D$ and $(M'-D') >= (M-D)$ are non-lossy; for any case where $M' < M$, $D' < D$, or both, only a lossy conversion can be made.

  For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See Section 12.18.4, "Rounding Behavior", for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

  Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first N characters of the string on the slave, where N is the width of the target column.

  > **Important**
  >
  > Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

  Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first N bytes of the string on the slave, where N is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

  When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where $M' > M$, the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the M bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

  When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where $M' < M$, the maximum possible value for the `BIT(M')` column is assigned; in other words, an "all-set" value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

16.4.1.11 Replication and DIRECTORY Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding

directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see Section 5.1.7, "Server SQL Modes".

16.4.1.12 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) was re-implemented in MySQL 5.1.18 to provide the following characteristics:

- The effects of the feature are always replicated.

- The following statements are replicated using statement-based replication:

    - `CREATE EVENT`

    - `ALTER EVENT`

    - `DROP EVENT`

    - `CREATE PROCEDURE`

    - `DROP PROCEDURE`

    - `CREATE FUNCTION`

    - `DROP FUNCTION`

    - `CREATE TRIGGER`

    - `DROP TRIGGER`

    However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

    > **Note**
    >
    > Attempting to replicate invoked features using statement-based replication produces the warning `Statement may not be safe to log in statement format`. (Prior to MySQL 5.1.36, this was `Statement is not safe to log in statement format`; see Bug #42415.) For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:

    - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).

    - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` were added to these tables in MySQL 5.1.18 to store this information. See

Section 20.7, "The INFORMATION_SCHEMA EVENTS Table", and Section 13.7.5.19, "SHOW EVENTS Syntax", for more information.

• The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where `event_name` is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID `master_id`, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED'
    AND   ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED'
    AND   ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
      FROM INFORMATION_SCHEMA.EVENTS
      WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

16.4.1.13 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Section 12.2, "Type Conversion in Expression Evaluation", and Section B.5.4.8, "Problems with Floating-Point Values".

16.4.1.14 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see Section 13.7.6.3, "FLUSH Syntax". The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

16.4.1.15 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, `LOAD_FILE()`, and `RAND()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See Section 16.1.2, "Replication Formats".)

  For early implementations of mixed-format logging, stored functions, triggers, and views that use these functions in their body do not replicate reliably in mixed-format logging mode because the logging did not switch from statement-based to row-based format. For example, `INSERT INTO t SELECT FROM v`, where `v` is a view that selects `UUID()` could cause problems. This limitation is lifted in MySQL 5.1.12.

  Beginning with MySQL 5.1.23, `USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #28086) (See also Section 16.4.1.7, "Replication of CURRENT_USER()".)

  Beginning with MySQL 5.1.42, `VERSION()` is also automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995) Beginning with MySQL 5.1.43, this is also true with regard to the `RAND()` function. (Bug #49222)

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. This can lead to a possibly unexpected result when replicating between MySQL servers in different time zones. Suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

Beginning with MySQL 5.1.42, `SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995)

See also Section 16.4.1.34, "Replication and Time Zones".

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

  Beginning with MySQL 5.1.42, these functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #47995)

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of @my_uuid is stored in the binary log as a user-variable event prior to the INSERT statement and is available for use in the INSERT.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, RAND() replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The FOUND_ROWS() and ROW_COUNT() functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the INSERT statement. For example, if you wish to store the result in a table named mytable, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating mytable, you should use SELECT ... INTO, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

Beginning with MySQL 5.1.23, these functions are automatically replicated using row-based replication when using MIXED mode, and generate a warning in STATEMENT mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.1.73, the value of LAST_INSERT_ID() was not replicated correctly if any filtering options such as --replicate-ignore-db and --replicate-do-table were enabled on the slave. (Bug #17234370, BUG# 69861)

16.4.1.16 Replication and LIMIT

Statement-based replication of LIMIT clauses in DELETE, UPDATE, and INSERT ... SELECT statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an ORDER BY clause.) Beginning with MySQL 5.1.24, when such a statement is encountered:

- When using STATEMENT mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

16.4.1.17 Replication and LOAD DATA INFILE

The `LOAD DATA INFILE` statement was not always replicated correctly to a slave running MySQL 5.1.42 or earlier from a master running MySQL 4.0 or earlier. When using statement-based replication, the `LOAD DATA INFILE` statement `CONCURRENT` option was not replicated. This issue was fixed in MySQL 5.1.43. This issue does not have any impact on `CONCURRENT` option handling when using row-based replication in MySQL 5.1 or later. (Bug #34628)

In MySQL 5.1.52 and later, `LOAD DATA INFILE` is considered unsafe (see Section 16.1.2.3, "Determination of Safe and Unsafe Statements in Binary Logging"). It causes a warning when using statement-based logging format, and is logged using row-based format when using mixed-format logging.

16.4.1.18 Replication and the Slow Query Log

Prior to MySQL 5.1.45, replication slaves did not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. (Bug #23300)

16.4.1.19 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

16.4.1.20 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement or `--master-connect-retry` option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 5.1.4, "Server System Variables".

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see Section 16.4.1.23, "Replication and Temporary Tables". Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates

and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.

- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. Writes are not forced to disk because the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

16.4.1.21 Replication and max_allowed_packet

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Prior to MySQL 5.1.40, `Last_IO_Error` and `Last_IO_Errno` in the output of `SHOW SLAVE STATUS` were not set in the event that replication failed due to exceeding `max_allowed_packet` (Bug #42914).

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

16.4.1.22 Replication and MEMORY Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.

- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in MySQL Cluster, where `slave_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see Section 16.4.1.38, "Replication and Variables"). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See Section 14.9, "The MEMORY Storage Engine", for more information about `MEMORY` tables.

16.4.1.23 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when `binlog_format=ROW` because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the slave can be an issue, whenever `binlog_format` is `STATEMENT` or `MIXED`, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see RBL, RBR, and temporary tables.

Safe slave shutdown when using temporary tables. Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.

2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.

3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.

4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

Temporary tables and replication options. By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

16.4.1.24 Replication of the mysql System Database

MySQL 5.1.14 and later. Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statement are replicated using the row-based format. However, statements that would normally update this information

indirectly—such `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

MySQL 5.1.13 and earlier.   User privileges are replicated only if the `mysql` database is replicated. That is, the `GRANT`, `REVOKE`, `SET PASSWORD`, `CREATE USER`, and `DROP USER` statements take effect on the slave only if the replication setup includes the `mysql` database.

16.4.1.25 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see Section 16.4.1.16, "Replication and LIMIT", for a detailed discussion of these.

16.4.1.26 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see Section 16.4.1.10, "Replication with Differing Table Definitions on Master and Slave").

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

16.4.1.27 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `range` on a 5.0 master that is replicating to a 5.1 or higher slave because `RANGE` is a reserved word beginning in MySQL 5.1. Replication can fail in such cases with Error 1064 `You have an error in your SQL syntax...`, *even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.

- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (`` ` ``).

For listings of reserved words by MySQL version, see Reserved Words, in the *MySQL Server Version Reference*. For identifier quoting rules, see Section 9.2, "Schema Object Names".

16.4.1.28 SET PASSWORD and Row-Based Replication

Row-based replication of `SET PASSWORD` statements from a MySQL 5.1 master to a MySQL 5.5 slave did not work correctly prior to MySQL 5.1.53 on the master and MySQL 5.5.7 on the slave (see Bug #57098, Bug #57357).

16.4.1.29 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

16.4.1.30 Replication of Server-Side Help Tables

The server maintains tables in the `mysql` database that store information for the `HELP` statement (see Section 13.8.3, "HELP Syntax". These tables can be loaded manually as described at Section 5.1.9, "Server-Side Help".

Help table content is derived from the MySQL Reference Manual. There are versions of the manual specific to each MySQL release series, so help content is specific to each series as well. Normally, you load a version of help content that matches the server version. This has implications for replication. For example, you would load MySQL 5.5 help content into a MySQL 5.5 master server, but not necessarily replicate that content to a MySQL 5.6 slave server for which 5.6 help content is more appropriate.

This section describes how to manage help table content upgrades when your servers participate in replication. Server versions are one factor in this task. Another is that help table structure may differ between the master and the slave.

Assume that help content is stored in a file named `fill_help_tables.sql`. In MySQL distributions, this file is located under the `share` or `share/mysql` directory, and the most recent version is always available for download from http://dev.mysql.com/doc/index-other.html.

To upgrade help tables, using the following procedure. Connection parameters are not shown for the `mysql` commands discussed here; in all cases, connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database.

1. Upgrade your servers by running `mysql_upgrade`, first on the slaves and then on the master. This is the usual principle of upgrading slaves first.

2. Decide whether you want to replicate help table content from the master to its slaves. If not, load the content on the master and each slave individually. Otherwise, check for and resolve any incompatibilities between help table structure on the master and its slaves, then load the content into the master and let it replicate to the slaves.

   More detail about these two methods of loading help table content follows.

Loading Help Table Content Without Replication to Slaves

To load help table content without replication, run this command on the master and each slave individually, using a `fill_help_tables.sql` file containing content appropriate to the server version (enter the command on one line):

```
mysql --init-command="SET sql_log_bin=0"
  mysql < fill_help_tables.sql
```

Use the `--init-command` option on each server, including the slaves, in case a slave also acts as a master to other slaves in your replication topology. The `SET` statement suppresses binary logging. After the command has been run on each server to be upgraded, you are done.

Loading Help Table Content With Replication to Slaves

If you do want to replicate help table content, check for help table incompatibilities between your master and its slaves. The `url` column in the `help_category` and `help_topic` tables was originally `CHAR(128)`, but is `TEXT` in newer MySQL versions to accommodate longer URLs. To check help table structure, use this statement:

```
SELECT TABLE_NAME, COLUMN_NAME, COLUMN_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'mysql'
AND COLUMN_NAME = 'url';
```

For tables with the old structure, the statement produces this result:

```
+---------------+-------------+-------------+
| TABLE_NAME    | COLUMN_NAME | COLUMN_TYPE |
+---------------+-------------+-------------+
| help_category | url         | char(128)   |
| help_topic    | url         | char(128)   |
+---------------+-------------+-------------+
```

For tables with the new structure, the statement produces this result:

```
+---------------+-------------+-------------+
| TABLE_NAME    | COLUMN_NAME | COLUMN_TYPE |
+---------------+-------------+-------------+
| help_category | url         | text        |
| help_topic    | url         | text        |
+---------------+-------------+-------------+
```

If the master and slave both have the old structure or both have the new structure, they are compatible and you can replicate help table content by executing this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

If the master and slave have incompatible help tables (one server has the old structure and the other has the new), you have a choice between not replicating help table content after all, or making the table structures compatible so that you can replicate the content.

- If you decide not to replicate the content after all, upgrade the master and slaves individually using `mysql` with the `--init-command` option, as described previously.

- If instead you decide to make the table structures compatible, upgrade the tables on the server that has the old structure. Suppose that your master server has the old table structure. Upgrade its tables to the new structure manually by executing these statements (binary logging is disabled here to prevent replication of the changes to the slaves, which already have the new structure):

```
SET sql_log_bin=0;
ALTER TABLE mysql.help_category ALTER COLUMN url TEXT;
ALTER TABLE mysql.help_topic ALTER COLUMN url TEXT;
```

Then run this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

16.4.1.31 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see Section 5.1.7, "Server SQL Modes".

16.4.1.32 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDBCLUSTER TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the slave automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see Section 5.1.6, "Server Status Variables".

16.4.1.33 Replication and TIMESTAMP

Older versions of MySQL (prior to 4.1) differed significantly in several ways in their handling of the `TIMESTAMP` data type from what is supported in MySQL versions 5.1 and newer; these include syntax extensions which are deprecated in MySQL 5.1, and that no longer supported in MySQL 5.5. This can cause problems (including replication failures) when replicating between MySQL Server versions, if you are using columns that are defined using the old `TIMESTAMP(N)` syntax. See Section 2.13.1.1, "Changes Affecting Upgrades to 5.1", for more information about the differences, how they can impact MySQL replication, and what you can do if you encounter such problems.

16.4.1.34 Replication and Time Zones

The same system time zone should be set for both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also Section 16.4.1.15, "Replication and System Functions".

`CONVERT_TZ(...,...,@@session.time_zone)` is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

16.4.1.35 Replication and Transactions

Mixing transactional and nontransactional statements within the same transaction. In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

As of MySQL 5.1.44, the server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

Transactional, nontransactional, and mixed statements.
To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that changes both nontransactional and transactional tables is considered "mixed". Mixed statements, like transactional statements, are cached and logged when the transaction commits.

> **Note**
>
> A mixed statement is unrelated to mixed binary logging format.

Before MySQL 5.1.44, the rules for binary logging are similar to those just described, except that there is no `binlog_direct_non_transactional_updates` system variable to affect logging of transactional

statements. Thus, the server immediately logs only the initial nontransactional statements in a transaction and caches the rest until commit time.

Before MySQL 5.1.31, the *effect* of the rules differs because the definition of transactional statement is different: In these earlier versions, a statement is nontransactional if the first changes it makes change nontransactional tables, transactional if the first changes it makes change transactional tables. "First" applies in the sense that a statement may have several effects if it involves such things as triggers, stored functions, or multiple-table updates. A mixed statement that changes both nontransactional and transactional tables is handled as nontransactional or transactional depending on the type of changes it makes first.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

Using different storage engines on master and slave.   It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN` ... `COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

Beginning with MySQL 5.1.48, it is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases (beginning with MySQL 5.1.48), an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

Beginning with MySQL Cluster NDB 6.2.14 and MySQL 5.1.24, every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. However, this does *not* apply to nontransactional changes; any statements affecting tables using a nontransactional storage engine such as `MyISAM` are regarded for this purpose as nontransactional, even when `autocommit` is enabled. (Bug #26395)

16.4.1.36 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

Before MySQL 5.1.31, a trigger that was defined on a transactional table but that updated a nontransactional table could cause updates on the transactional table to be replicated before they were actually committed on the master, and not be rolled back correctly on the slave if they were rolled back on the master. (Bug #40116) See also Section 16.4.1.35, "Replication and Transactions".

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. Beginning with MySQL 5.1.40, such statements are marked as unsafe. (Bug #45677)

16.4.1.37 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

Beginning with MySQL 5.1.32, `TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in Section 13.1.34, "TRUNCATE TABLE Syntax" governing such tables. (Bug #36763)

16.4.1.38 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`

- `timestamp`

- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See Section 5.4.4.3, "Mixed Binary Logging Format".

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = ` *mode* statement, the full *mode* value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see Section 16.4.1.22, "Replication and MEMORY Tables".

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See Section 16.1.2, "Replication Formats".

In MySQL 5.1.20 and later (and in MySQL 5.0.46 and later in MySQL 5.0, for backward compatibility), the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`

- `foreign_key_checks`

- `unique_checks`

- `character_set_client`

- `collation_connection`

- `collation_database`

- `collation_server`

- `sql_auto_is_null`

> **Important**
>
> Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

It is strongly recommended that you always use the same setting for the `lower_case_table_names` system variable on both master and slave. In particular, when a case-sensitive file system is used, setting this variable to 1 on the slave, but to a different value on the master, can cause two types of problems: Names of databases are not converted to lowercase; in addition, when using row-based replication names of tables are also not converted. Either of these problems can cause replication to fail. This is a known issue, which is fixed in MySQL 5.6.

16.4.1.39 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a samed-named view is supported using statement-based logging, but not when using row-based logging. In MySQL 5.1.69 and later, trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

16.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.0 to a slave running MySQL 5.1, from a master running MySQL 5.1 to a slave running MySQL 5.5, and so on.

However, one may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.1.31, MySQL 5.1.32, and MySQL 5.1.34 concurrently, although you could use any two of these releases together.

> **Important**
>
> It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.**   The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary

log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA INFILE`, and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

This also has significant implications for upgrading replication servers; see Section 16.4.3, "Upgrading a Replication Setup", for more information.

• **Use of row-based replication.**   Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.1 or later master to a slave older than MySQL 5.1.5.

For more information about row-based replication, see Section 16.1.2, "Replication Formats".

• **SQL incompatibilities.**   You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see Section 16.4.1, "Replication Features and Issues".

16.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see Section 2.13.1, "Upgrading MySQL"

When you upgrade a master to 5.1 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.1.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.1.x version, restart it, and restart replication. The 5.1 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.1 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.1.x release as the slaves, and restart it. The 5.1 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.1 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.1 format. These too are recognized by the 5.1 slaves.

In other words, when upgrading to MySQL 5.1, the slaves must be MySQL 5.1 before you can upgrade the master to 5.1. Note that downgrading from 5.1 to older versions does not work so simply: You must ensure that any 5.1 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binary log. See Section 16.1.2, "Replication Formats".

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at Section 2.13.1.1, "Changes Affecting Upgrades to 5.1". It is safest

to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.

2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.

4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.

5. Restart the slaves, this time without the `--skip-slave-start` option.

16.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.

- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.

- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.

- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See Section 16.2.1, "Replication Implementation Details". If the I/O thread state says `Connecting to master`, check the following:

  - Verify the privileges for the user being used for replication on the master.

  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.

  - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.

- If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.

- Check that you can reach the master by using `ping` or `traceroute`/`tracert` to reach the host.

- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 16.4.1, "Replication Features and Issues". If it is a bug, see Section 16.4.5, "How to Report Replication Bugs or Problems", for instructions on how to report it.

- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:

  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.

  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.

  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

     ```
     mysql> SET GLOBAL sql_slave_skip_counter = N;
     mysql> START SLAVE;
     ```

     The value of N should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

     See also Section 13.4.2.6, "SET GLOBAL sql_slave_skip_counter Syntax".

  4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

16.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.7, "How to Report Bugs or Problems". If you have a "phantom" problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the

slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*

2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:

   • All binary log files from the master

   • All binary log files from the slave

   • The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem

   • The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem

   • Error logs from the master and the slave

4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. *log_file* and *log_pos* are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.7, "How to Report Bugs or Problems".

Chapter 17 MySQL Cluster NDB 6.1 - 7.1

Table of Contents

This chapter contains information about *MySQL Cluster*, which is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Current releases of MySQL Cluster use versions 6 and 7 of the `NDB` storage engine (also known as `NDBCLUSTER`) to enable running several computers with MySQL servers and other software in a cluster.

Beginning with MySQL 5.1.24, support for the `NDBCLUSTER` storage engine was removed from the standard MySQL server binaries built by MySQL. Instead, users of MySQL Cluster binaries built by MySQL should upgrade to the most recent binary release of MySQL Cluster NDB 7.0 or MySQL Cluster 7.1 for supported platforms—these include RPMs that should work with most Linux distributions. MySQL Cluster users who build from source should be aware that, also beginning with MySQL 5.1.24, `NDBCLUSTER` sources in the standard MySQL 5.1 tree are no longer maintained; these users should use the sources provided for MySQL Cluster NDB 7.0 or later. (Locations where the sources can be obtained are listed later in this section.)

Note

MySQL Cluster NDB 6.1, 6.2, and 6.3 were formerly known as "MySQL Cluster Carrier Grade Edition". Beginning with MySQL Cluster NDB 6.2.15 and MySQL Cluster NDB 6.3.14, this term is no longer applied to the MySQL Cluster software —which is now known simply as "MySQL Cluster"—but rather to a commercial licensing and support package. You can learn more about available options for

> commercial licensing of MySQL Cluster from http://mysql.com/products/database/cluster/features.html, on the MySQL web site.

This chapter contains information about MySQL Cluster in MySQL 5.1 mainline releases through MySQL 5.1.23, MySQL Cluster NDB 6.2 releases through 5.1.51-ndb-6.2.19, MySQL Cluster NDB 6.3 releases through 5.1.73-ndb-6.3.55, MySQL Cluster NDB 7.0 releases through 5.1.73-ndb-7.0.42 and MySQL Cluster NDB 7.1 releases through 5.1.77-ndb-7.1.37. Currently, the MySQL Cluster NDB 7.3 and MySQL Cluster NDB 7.4 release series are both Generally Available (GA). MySQL Cluster NDB 7.2 is a previous GA release series; although this series is still supported, we recommend that new deployments use MySQL Cluster NDB 7.4. For information about MySQL Cluster NDB 7.4, see MySQL Cluster NDB 7.3 and MySQL Cluster NDB 7.4, in the *MySQL 5.6 Manual*. MySQL Cluster NDB 7.5 is also available as a Developer Preview; see MySQL Cluster NDB 7.5.

This chapter also contains historical information about MySQL Cluster NDB 6.1 and MySQL Cluster NDB 6,2, although these release series are no longer in active development, and no longer supported for new deployments. You should upgrade to a MySQL Cluster NDB 7.1 or later release series as soon as possible.

Release notes for the changes in each release of MySQL Cluster are located at MySQL Cluster 7.1 Release Notes.

Supported Platforms.   MySQL Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to http://www.mysql.com/support/supportedplatforms/cluster.html.

Availability.   MySQL Cluster binary and source packages are available for supported platforms from http://dev.mysql.com/downloads/cluster/.

> **Note**
>
> Binary releases and RPMs were not available for MySQL Cluster NDB 6.2 prior to MySQL Cluster NDB 6.2.15.

MySQL Cluster release numbers.   Starting with MySQL Cluster NDB 6.1 and MySQL Cluster NDB 6.2, MySQL Cluster follows a somewhat different release pattern from the mainline MySQL 5.1 Cluster series of releases. In this *Manual* and other MySQL documentation, we identify these and later MySQL Cluster releases employing a version number that begins with "NDB". This version number is that of the NDBCLUSTER storage engine used in the release, and not of the MySQL server version on which the MySQL Cluster release is based.

Version strings used in MySQL Cluster NDB 6.x and 7.x software.   The version string displayed by MySQL Cluster NDB 6.x and 7.x software uses this format:

```
mysql-mysql_server_version-ndb-ndb_engine_version
```

mysql_server_version represents the version of the MySQL Server on which the MySQL Cluster release is based. For all MySQL Cluster NDB 6.x and 7.x releases, this is "5.1". *ndb_engine_version* is the version of the NDB storage engine used by this release of the MySQL Cluster software. You can see this format used in the mysql client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.1.77-ndb-7.1.37 Source distribution
```

```
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
*************************** 1. row ***************************
VERSION(): 5.1.77-ndb-7.1.37
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the SHOW command in the ndb_mgm client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @10.0.10.6  (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2    @10.0.10.8  (5.1.77-ndb-7.1.37, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3    @10.0.10.2  (5.1.77-ndb-7.1.37)

[mysqld(API)]   2 node(s)
id=4    @10.0.10.10  (5.1.77-ndb-7.1.37)
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the MySQL Cluster release was branched and the version of the NDBCLUSTER storage engine used. For example, the full version string for MySQL Cluster NDB 7.0.5 (the first GA MySQL Cluster NDB 7.0 binary release) was mysql-5.1.32-ndb-7.0.5. From this we can determine the following:

• Since the portion of the version string preceding "-ndb-" is the base MySQL Server version, this means that MySQL Cluster NDB 7.0.5 derives from the MySQL 5.1.32, and contains all feature enhancements and bugfixes from MySQL 5.1 up to and including MySQL 5.1.32.

• Since the portion of the version string following "-ndb-" represents the version number of the NDB (or NDBCLUSTER) storage engine, MySQL Cluster NDB 7.0.5 uses version 7.0.5 of the NDBCLUSTER storage engine.

New MySQL Cluster releases are numbered according to updates in the NDB storage engine, and do not necessarily correspond in a linear fashion with mainline MySQL Server releases. For example, MySQL Cluster NDB 7.0.5 (as previously noted) is based on MySQL 5.1.32, and MySQL Cluster NDB 7.0.6 is based on MySQL 5.1.34 (version string: mysql-5.1.34-ndb-7.0.6).

Compatibility with standard MySQL 5.1 releases.   While many standard MySQL schemas and applications can work using MySQL Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using MySQL Cluster (see Section 17.1.6, "Known Limitations of MySQL Cluster"). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, MyISAM or InnoDB—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications. Moreover, from MySQL 5.1.24 onwards, the MySQL Server and MySQL Cluster codebases diverge considerably (and NDB storage engine support dropped from subsequent MySQL Server releases), so that the standard mysqld cannot function as a dropin replacement for the version of mysqld that is supplied with MySQL Cluster.

MySQL Cluster development source trees.   MySQL Cluster development trees can also be accessed from https://github.com/mysql/mysql-server.

The MySQL Cluster development sources maintained at https://github.com/mysql/mysql-server are licensed under the GPL. For information about obtaining MySQL sources using Bazaar and building them yourself, see Section 2.11.3, "Installing MySQL Using a Development Source Tree".

Currently, MySQL Cluster NDB 7.3 and MySQL Cluster NDB 7.4 releases are Generally Available (GA). We recommend that new deployments use MySQL Cluster NDB 7.4. MySQL Cluster NDB 7.1 and earlier versions are no longer in active development. For an overview of major features added in MySQL Cluster NDB 7.4, see What is New in MySQL Cluster NDB 7.4. For similar information about MySQL Cluster NDB 7.3, see What is New in MySQL Cluster NDB 7.3. MySQL Cluster NDB 7.2 is a past GA series that is still supported; see What is New in MySQL Cluster. MySQL Cluster NDB 7.5 is also available as a Developer Preview for testing of new features; for more information, see MySQL Cluster NDB 7.5.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL Web site at http://www.mysql.com/products/cluster/.

Additional Resources.   More information about MySQL Cluster can be found in the following places:

- For answers to some commonly asked questions about MySQL Cluster, see Section A.10, "MySQL 5.1 FAQ: MySQL Cluster".

- The MySQL Cluster mailing list: http://lists.mysql.com/cluster.

- The MySQL Cluster Forum: http://forums.mysql.com/list.php?25.

- Many MySQL Cluster users and developers blog about their experiences with MySQL Cluster, and make feeds of these available through PlanetMySQL.

17.1 MySQL Cluster Overview

MySQL Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB (which stands for "*N*etwork *D*ata*B*ase"). In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas "MySQL Cluster" refers to the combination of one or more MySQL servers with the NDB storage engine.

A MySQL Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in a MySQL Cluster is shown here:

Figure 17.1 MySQL Cluster Components
All these programs work together to form a MySQL Cluster (see Section 17.4, "MySQL Cluster Programs". When data is stored by the NDB storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although a MySQL Cluster SQL node uses the mysqld server daemon, it differs in a number of critical respects from the mysqld binary supplied with the MySQL 5.1 distributions, and the two versions of mysqld are not interchangeable.

In addition, a MySQL server that is not connected to a MySQL Cluster cannot use the NDB storage engine and cannot access any MySQL Cluster data.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster"). In MySQL Cluster NDB 7.0 and later, rolling restarts are also used as part of the process of adding new data nodes online (see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online"). For more information about data nodes, how they are organized in a MySQL Cluster, and how they handle and store MySQL Cluster data, see Section 17.1.2, "MySQL Cluster Nodes, Node Groups, Replicas, and Partitions".

Backing up and restoring MySQL Cluster databases can be done using the NDB-native functionality found in the MySQL Cluster management client and the ndb_restore program included in the MySQL Cluster distribution. For more information, see Section 17.5.3, "Online Backup of MySQL Cluster", and Section 17.4.20, "ndb_restore — Restore a MySQL Cluster Backup". You can also use the standard MySQL functionality provided for this purpose in mysqldump and the MySQL server. See Section 4.5.4, "mysqldump — A Database Backup Program", for more information.

MySQL Cluster nodes can use a number of different transport mechanisms for inter-node communications, including TCP/IP using standard 100 Mbps or faster Ethernet hardware. It is also possible to use the high-

speed *Scalable Coherent Interface* (SCI) protocol with MySQL Cluster, although this is not required to use MySQL Cluster. SCI requires special hardware and software; see Section 17.3.4, "Using High-Speed Interconnects with MySQL Cluster", for more about SCI and using it with MySQL Cluster.

17.1.1 MySQL Cluster Core Concepts

`NDBCLUSTER` (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The "Cluster" portion of MySQL Cluster is configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a *node*.

> **Note**
>
> In many contexts, the term "node" is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- *Management node*: The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.

- *Data node*: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see Section 17.1.2, "MySQL Cluster Nodes, Node Groups, Replicas, and Partitions"). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see Section 17.4.1, "`ndbd` — The MySQL Cluster Data Node Daemon"). In MySQL Cluster NDB 7.0 and later, `ndbmtd` can also be used for the data node process; see Section 17.4.3, "`ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)", for more information.

  MySQL Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to MySQL Cluster as an *in-memory* database). In MySQL 5.1, MySQL Cluster NDB 6.X, and later, some MySQL Cluster data can be stored on disk; see Section 17.5.12, "MySQL Cluster Disk Data Tables", for more information.

- *SQL node*: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

  An SQL node is actually just a specialized type of *API node*, which designates any application which accesses MySQL Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

⚠️

Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from MySQL Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see Section 17.1.2, "MySQL Cluster Nodes, Node Groups, Replicas, and Partitions".

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, `NDB`-specific API programs, and management clients. These are described in the next few paragraphs.

Standard MySQL clients. MySQL Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as MySQL Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using a MySQL Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with MySQL Cluster, see Using Connector/J with MySQL Cluster.

NDB client programs. Client programs can be written that access MySQL Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

Beginning with MySQL Cluster NDB 7.1, `NDB`-specific Java applications can also be written for MySQL Cluster, using the *MySQL Cluster Connector for Java*. This MySQL Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. Support is also provided in MySQL Cluster NDB 7.1 and later for *ClusterJPA*, an OpenJPA implementation for MySQL Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL's query optimizer are sent through the MySQL Server, using JDBC. See Java and MySQL Cluster, and The ClusterJ API and Data Object Model, for more information.

Management clients. These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with MySQL Cluster (see Section 17.4.5, "`ndb_mgm`

— The MySQL Cluster Management Client"). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more MySQL Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex MySQL Cluster management tasks, such restarting a MySQL Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to MySQL Cluster. See MySQL™ Cluster Manager 1.3.6 User Manual, for more information.

Event logs.   MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 17.5.6, "Event Reports Generated in MySQL Cluster". Event logs are of the two types listed here:

• *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.

• *Node log*: A separate log which is also kept for each individual node.

> **Note**
>
> Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Checkpoint.   Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to MySQL Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the `NDB` storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

• *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

• *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see MySQL Cluster Data Node File System Directory Files.

17.1.2 MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

(Data) Node.   An `ndbd` process, which stores a *replica* —that is, a copy of the *partition* (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple `ndbd` processes on a single computer, such a configuration is not supported.

It is common for the terms "node" and "data node" to be used interchangeably when referring to an `ndbd` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

Node Group.   A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

The number of node groups in a MySQL Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (`NoOfReplicas` configuration parameter), as shown here:

```
[number_of_node_groups] = number_of_data_nodes / NoOfReplicas
```

Thus, a MySQL Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Replicas are discussed later in this section; for more information about `NoOfReplicas`, see Section 17.3.3.6, "Defining MySQL Cluster Data Nodes".

> **Note**
>
> All node groups in a MySQL Cluster must have the same number of data nodes.

Prior to MySQL Cluster NDB 7.0, it was not possible to add new data nodes to a MySQL Cluster without shutting down the cluster completely and reloading all of its data. In MySQL Cluster NDB 7.0 (beginning with MySQL Cluster version NDB 6.4.0), you can add new node groups (and thus new data nodes) to a running MySQL Cluster—see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online", for information about how this can be done.

Partition.   This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

NDB and user-defined partitioning.   MySQL Cluster normally partitions `NDBCLUSTER` tables automatically. However, in MySQL 5.1 and later MySQL Cluster releases, it is possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only the `KEY` and `LINEAR KEY` partitioning schemes are supported in production with `NDB` tables.

2. When using `ndbd`, the maximum number of partitions that may be defined explicitly for any `NDB` table is `8 * [number of node groups]`. (The number of node groups in a MySQL Cluster is determined as discussed previously in this section.)

   When using `ndbmtd`, this maximum is also affected by the number of local query handler threads, which is determined by the value of the `MaxNoOfExecutionThreads` configuration parameter. In such cases, the maximum number of partitions that may be defined explicitly for an `NDB` table is equal to `4 * MaxNoOfExecutionThreads * [number of node groups]`.

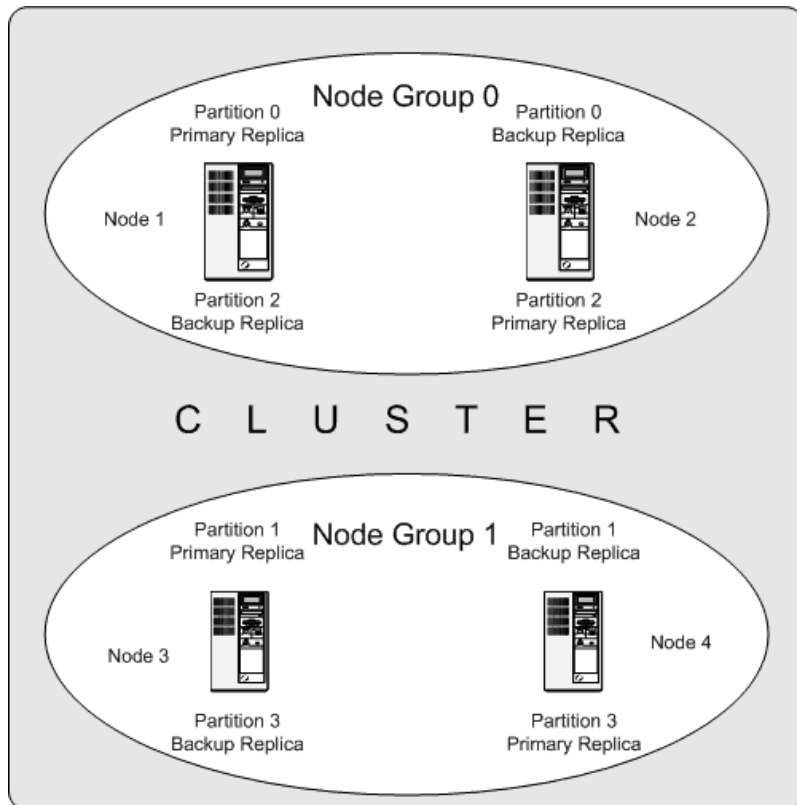
   See Section 17.4.3, "`ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)", for more information.

For more information relating to MySQL Cluster and user-defined partitioning, see Section 17.1.6, "Known Limitations of MySQL Cluster", and Section 18.5.2, "Partitioning Limitations Relating to Storage Engines".

Replica.   This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note

that only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgm` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

Figure 17.2 MySQL Cluster with Two Node Groups


The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.

- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.

- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.

- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

Figure 17.3 Nodes Required for a 2x2 Cluster
In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster "alive" (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an **X**); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

17.1.3 MySQL Cluster Hardware, Software, and Networking Requirements

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 17.5.12, "MySQL Cluster Disk Data Tables", for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other MySQL Cluster processes are relatively small.

The software requirements for MySQL Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use MySQL Cluster. We assume that you are using the binaries appropriate to your platform, available from the MySQL Cluster software downloads page at http://dev.mysql.com/downloads/cluster/.

For communication between nodes, MySQL Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between MySQL Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your MySQL Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

See Section 17.5.11.1, "MySQL Cluster Security and Networking Issues", for more information.

- **Efficiency.**   Setting up a MySQL Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to MySQL Cluster data, it also ensures that MySQL Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

Network communication and latency.   MySQL Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, MySQL Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, a MySQL Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for MySQL Cluster, care must be taken care to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 μs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where MySQL Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

SCI support.   It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See Section 17.3.4, "Using High-Speed Interconnects with MySQL Cluster", for more about this protocol and its use with MySQL Cluster.

17.1.4 MySQL Cluster Development History

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x, as compared to earlier MySQL Cluster releases.

There are a number of significant changes in the implementation of the `NDBCLUSTER` storage engine in mainline MySQL 5.1 releases up to and including MySQL 5.1.23 as compared to that in MySQL 5.0; MySQL Cluster NDB 6.x and 7.x make further changes and improvements in MySQL Cluster in addition to these. The changes and features most likely to be of interest are shown in the following tables:

MySQL Cluster NDB 7.2
Distribution of MySQL users and privileges across MySQL Cluster SQL nodes
Distributed pushed-down joins, with greatly improved performance for many joins that can thus be pushed down and executed in parallel on the data nodes.
Improved default values for data node configuration parameters.

MySQL Cluster NDB 7.1
Production-level support for MySQL Cluster on Microsoft Windows platforms.
`ndbinfo` meta-information database
MySQL Cluster Connector for Java, including ClusterJ and OpenJPA (ClusterJPA) support
Native support for default column values

MySQL Cluster NDB 7.0
Multi-threaded data nodes (`ndbmtd` data node daemon)
Online addition of data nodes; online data redistribution
MySQL on Windows (alpha; source releases only)
Configuration cache
Backup snapshots (`START BACKUP ... SNAPSHOTSTART`, `START BACKUP ... SNAPSHOTEND` commands)
IPv6 support for geo-replication
Protected DDL operations
Dynamic buffering for NDB transporters
Increased flexibility in determining arbitration handling, using a new `Arbitration` data node configuration parameter
NDB API counters and associated status variables, which make it possible to observe the API-level effects of SQL statements on `NDB` tables from the `mysql` client.

MySQL Cluster NDB 6.3
Conflict detection and resolution for multi-master replication
Compressed backups and local checkpoints
Support for `OPTIMIZE TABLE`
Parallel data node recovery
Enhanced transaction coordinator selection
Improved SQL statement performance metrics
Transaction batching
`ndb_restore` attribute promotion
Support for `epoll` (Linux only)

MySQL Cluster NDB 6.3
Distribution awareness
`NDB` thread locks; realtime extensions for multiple CPUs

MySQL Cluster NDB 6.2
Improved backup status reporting (`BackupReportFrequency`, `REPORT BackupStatus`)
Multiple connections per SQL node
Data access with `NdbRecord` (NDB API)
`REPORT MemoryUsage` command
Memory allocation improvements
Management client connection control
Micro-GCPs
Online `ADD COLUMN`; improved online index creation

MySQL Cluster NDB 6.1
Greater number of cluster nodes
Disabling of arbitration
Additional `DUMP` commands
Faster Disk Data backups
Batched slave updates

MySQL 5.1 (through 5.1.23)
MySQL Cluster Replication
Disk Data storage
Variable-size columns
User-defined partitioning
Autodiscovery of table schema changes
Online adding and dropping of indexes

17.1.4.1 What is New in MySQL Cluster NDB 7.2.0

The following improvements to MySQL Cluster were made in MySQL Cluster NDB 7.2.0.

- **Distribution of MySQL users and privileges.**   Automatic distribution of MySQL users and privileges across all SQL nodes in a given MySQL Cluster is now supported. To enable this support, you must first import an SQL script `share/mysql/ndb_dist_priv.sql` that is included with the MySQL Cluster NDB 7.2 distribution. This script creates several stored procedures which you can use to enable privilege distribution and perform related tasks.

  When a new MySQL Server joins a MySQL Cluster where privilege distribution is in effect, it also participates in the privilege distribution automatically.

  Once privilege distribution is enabled, all changes to the grant tables made on any `mysqld` attached to the cluster are immediately available on any other attached MySQL Servers. This is true whether the changes are made using `CREATE USER`, `GRANT`, or any of the other statements described elsewhere in

this Manual (see Section 13.7.1, "Account Management Statements".) This includes privileges relating to stored routines and views; however, automatic distribution of the views or stored routines themselves is not currently supported.

For more information, see Section 17.5.14, "Distributed MySQL Privileges for MySQL Cluster".

- **Distributed pushed-down joins.** Many joins can now be pushed down to the NDB kernel for processing on MySQL Cluster data nodes. Previously, a join was handled in MySQL Cluster by means of repeated accesses of `NDB` by the SQL node; however, when pushed-down joins are enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join, leading to greatly improved performance of join processing.

  It is possible to determine when joins can be pushed down to the data nodes by examining the join with `EXPLAIN`. A number of new system status variables (`Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`) and additions to the `counters` table (in the `ndbinfo` information database) can also be helpful in determining when and how well joins are being pushed down.

  More information and examples are available in the description of the `ndb_join_pushdown` server system variable. See also the description of the status variables referenced in the previous paragraph, as well as Section 17.5.10.7, "The ndbinfo counters Table".

- **Improved default values for data node configuration parameters.** In order to provide more resiliency to environmental issues and better handling of some potential failure scenarios, and to perform more reliably with increases in memory and other resource requirements brought about by recent improvements in join handling by `NDB`, the default values for a number of MySQL Cluster data node configuration parameters have been changed. The parameters and changes are described in the following list:

  - `HeartbeatIntervalDbDb`: Default increased from 1500 ms to 5000 ms.

  - `ArbitrationTimeout`: Default increased from 3000 ms to 7500 ms.

  - `TimeBetweenEpochsTimeout`: Now effectively disabled by default (default changed from 4000 ms to 0).

  - `SharedGlobalMemory`: Default increased from 20 MB to 128 MB.

  - `MaxParallelScansPerFragment`: Default increased from 32 to 256.

  In addition, the value computed for `MaxNoOfLocalScans` when this parameter is not set in `config.ini` has been increased by a factor of 4.

MySQL Cluster NDB 7.2.1 and later MySQL Cluster NDB 7.2 releases are based on MySQL Server 5.5 and are not covered here. See MySQL Cluster NDB 7.2.

17.1.4.2 What is New in MySQL Cluster NDB 7.1

The following improvements to MySQL Cluster have been made in MySQL Cluster NDB 7.1.

- **MySQL Cluster information database (ndbinfo).** The `ndbinfo` information database makes it possible to obtain real-time characteristics of a MySQL Cluster by issuing queries from the `mysql` client or other MySQL client applications. `ndbinfo` provides metadata specific to MySQL Cluster similarly to how the `INFORMATION_SCHEMA` database provides metadata for the standard MySQL Server. This

eliminates much of the need to read log files, issue `REPORT` or `DUMP` commands in the `ndb_mgm` client, or parse the output of `ndb_config` in order to get configuration and status information from a running MySQL Cluster.

For more information, see Section 17.5.10, "The ndbinfo MySQL Cluster Information Database".

- **Java connectors for MySQL Cluster.**   The MySQL Cluster distribution now includes 2 new Java user APIs, ClusterJ and ClusterJPA. ClusterJ is an object-relational interface in a manner similar to that of Java persistence frameworks such as Hibernate. Cluster JPA is a reimplementation of OpenJPA. ClusterJ uses a backend library (NdbJTie) that provides access to the `NDB` storage engine without using a MySQL Server connection or JDBC. ClusterJPA also uses NdbJTie when it improves performance, but can also process complex queries using JDBC and a MySQL Server connection, where it can take advantage of the MySQL query optimizer.

  ClusterJ and Cluster JPA can also be made to work with recent MySQL Cluster NDB 7.0 releases although the necessary library and JAR files are included only in MySQL Cluster NDB 7.1.1 and later.

  For more information about using ClusterJ and ClusterJPA, see MySQL Cluster Connector for Java.

- **New CHANGE MASTER TO option for circular replication.**   Beginning with MySQL Cluster NDB 7.1.0, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

  See Section 13.4.2.1, "CHANGE MASTER TO Syntax", as well as Section 13.7.5.36, "SHOW SLAVE STATUS Syntax", for more information.

- **Native support for default column values.**   Starting with MySQL Cluster NDB 7.1.4, default values for table columns are stored in the NDB kernel rather than by the MySQL server as was done previously. This means that inserts on tables having column value defaults can be smaller and faster than before, because less data must be sent from SQL nodes to `NDBCLUSTER`.

  Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.1.4 and later; however, they do not support native default values until they are upgraded. You can upgrade a table with non-native default values to support native default values using an offline `ALTER TABLE` statement.

- **MySQL Cluster on Windows (Production).**   Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is available for production use on Microsoft Windows operating systems; MySQL Cluster NDB 7.1 binaries for Windows can be obtained from http://dev.mysql.com/downloads/cluster/.

  Features and behavior are generally comparable to those found on previously supported platforms such as Linux and Solaris. However, you must install the binaries manually.

  Beginning with MySQL Cluster NDB 7.1.5, MySQL Cluster processes can be run as Windows services.

  If you wish to build MySQL Cluster from source on Windows, you must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option. For more information, see Section 2.11.7, "Installing MySQL from Source on Windows".

- **--nowait-nodes option for management servers.**   It is now possible to configure a cluster with two management servers, but to start the cluster using only one of them by starting the management node daemon with the `--nowait-nodes` option. The other management server can then be started at a later time to join the running MySQL Cluster.

- **Improved lock handling for primary key lookups on BLOB tables.**   A MySQL Cluster table stores all but the first 256 bytes of any `BLOB` or `TEXT` column values in a separate `BLOB` table; when executing

queries against such tables, a shared lock is obtained. Prior to MySQL Cluster NDB 7.1.1, when the query used a primary key lookup and took place within a transaction, the lock was held for the duration of the transaction, even after no more data was being read from the `NDB` table. Now in such cases, the lock is released when all `BLOB` data associated with the table has been read. (Bug #49190)

> **Note**
>
> A shared lock is also taken for unique key lookups; it is still the case that this lock is held for the duration of the transaction.

- **Heartbeat thread policy and priority.**   Beginning with MySQL Cluster NDB 7.1.2, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

- **Improved access to partitioning information.**   The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 7.1.2, the `--blob-info` option causes this program to include partition information for `BLOB` tables in its output. Also beginning with MySQL Cluster NDB 7.1.2, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` option.

  Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 7.1.2.

- **Replication attribute promotion and demotion.**   Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

  The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

  For more information, see Attribute promotion and demotion (MySQL Cluster).

- **Change in ndbinfo database.**   The experimental `pools` table was removed from `ndbinfo` in MySQL Cluster NDB 7.1.3. Applications which used this table can and should be rewritten to use other `ndbinfo` tables.

- **Configuration caching control.**   Beginning with MySQL Cluster NDB 7.1.4, it is possible to disable the management server's configuration cache using the `--config-cache` option, which forces `ndb_mgmd` to read its configuration data from the `config.ini` configuration file every time it starts. For more information about configuration caching and this option, see Section 17.3.3, "MySQL Cluster Configuration Files". See also Section 17.4.4, "`ndb_mgmd` — The MySQL Cluster Management Server Daemon".

- **Incompatible change in NDB API event reporting.**   Beginning with MySQL Cluster NDB 7.1.4, DDL events are no longer reported on `Event` objects by default. Instead the desired level of event reporting (`EventReport` value) must be set explicitly using `Event::setReport()`.

- **Number of table attributes.**   Beginning with MySQL Cluster NDB 7.1.4, the maximum number of attributes (columns plus indexes) per table has been increased from 128 to 512.

- **InnoDB support in commercial binaries.**   Beginning with MySQL Cluster NDB 7.1.4b, all commercial binary releases of MySQL Cluster provide support for the `InnoDB` storage engine.

- **Heartbeat ordering.**   Beginning with MySQL Cluster NDB 7.1.5, it is possible to set a specific order for transmission of heartbeats between data nodes, using the `HeartbeatOrder` data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).

- **Relaxed ndb_restore column comparison rules.**   When restoring data, ndb_restore compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 7.1.5, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:

  - `COLUMN_FORMAT` setting (`FIXED`, `DYNAMIC`, or `DEFAULT`)

  - `STORAGE` setting (`MEMORY` or `DISK`)

  - The default value

  - The distribution key

  In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.

- **Storage of user data in anyValue.**   When writing NDB events to the binary log, MySQL Cluster uses `OperationOptions::anyValue` to store the server ID. Beginning with MySQL Cluster NDB 7.1.6, it is possible to store user data from an NDB API application in part of the `anyValue` when `mysqld` has been started with the `--server-id-bits` option set to a nondefault value. Also beginning with MySQL Cluster NDB 7.1.6, it is possible to view this data in the output of mysqlbinlog, for which its own `--server-id-bits` option is added.

- **--add-drop-trigger option for mysqldump.**   Beginning with MySQL Cluster NDB 7.1.8, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.

- **Forcing node shutdown and restart.**   In MySQL Cluster NDB 7.1.8 and later, it is possible using the `ndb_mgm` management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster. In the management client, this is implemented through the addition of the `-f` (force) option to the `STOP` and `RESTART` commands. For more information, see Section 17.5.2, "Commands in the MySQL Cluster Management Client". The MGM API also adds two new methods for forcing such a node shutdown or restart; see ndb_mgm_stop4(), and ndb_mgm_restart4(), for more information about these methods.

- **Disk Data usage statistics (diskpagebuffer table).**   MySQL Cluster 7.1.9 introduces a new table in the `ndbinfo` information database. The `diskpagebuffer` table provides real-time data on disk page buffer usage. These statistics can be used to monitor performance of MySQL Cluster Disk Data read and write operations, and can prove useful in the tuning of Disk Data parameters such as `DiskPageBufferMemory`.

- **InnoDB Plugin support.**   Beginning with MySQL Cluster NDB 7.1.9, the MySQL Server supplied with MySQL Cluster supports the `InnoDB` Plugin. For more information about enabling the plugin if you are building MySQL Cluster from source, see Section 17.2, "MySQL Cluster Installation and Upgrades".

> **Note**
>
> Due to a packaging issue, the `InnoDB` plugin was not included in RPMs for MySQL Cluster NDB 7.1.9; this issue was corrected in MySQL Cluster NDB 7.1.9a. (Bug #58283)

- **TimeBetweenEpochsTimeout and GCP stop control.**   Beginning with MySQL Cluster NDB 7.1.10, it is possible to disable GCP stops by setting `TimeBetweenEpochsTimeout` to 0. In addition, a warning is written to the cluster log whenever the time required for a GCP save exceeds 60 seconds or the time required for a GCP commit exceeds 10 seconds. This warning includes a report of the current value of `TimeBetweenEpochsTimeout`. For more information, see Disk Data and GCP Stop errors.

- **Skipping corrupted tables in NDB native backups.**   Beginning with MySQL Cluster NDB 7.1.10, you can cause `ndb_restore` to ignore tables that are corrupted due to missing blob parts tables by using the `--skip-broken-objects` option. When this option is used, such tables are skipped, and the restoration of any remaining uncorrupted tables in the backup continues.

- **BLOB read and write batching.**   Beginning with MySQL Cluster NDB 7.1.10, it possible to control batching of `BLOB` read and write operations. For SQL nodes, this can be done using the `--ndb-blob-read-batch-bytes` and `--ndb-blob-write-batch-bytes` options for `mysqld`. In NDB API applications, you can control batching of `BLOB` reads and writes using the `NdbTransaction` methods `setMaxPendingBlobReadBytes()`, `getMaxPendingBlobReadBytes()`, `setMaxPendingBlobWriteBytes()`, and `getMaxPendingBlobWriteBytes()`.

- **Restoring from a NDB native backup to a differently-named database.**   MySQL Cluster NDB 7.1.11 adds a new `--rewrite-database` option to `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup. The option can be used multiple times, and it is possible to restore from more than one source database in the backup to a single target database (although no protection against table or other object name collision is provided).

    See Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup", for more information.

- **Selective over-commit handling.**   Beginning with MySQL Cluster NDB 7.1.10, it is possible to exercise more direct control over uncommitted operations from transactions aborted due to timeouts flushing redo logs to disk. This is implemented using three configuration parameters added in this version of MySQL Cluster: the data node configuration parameters `RedoOverCommitCounter` and `RedoOverCommitLimit`, and the API node configuration parameter `DefaultOperationRedoProblemAction`.

    When an attempt to flush a given redo log takes longer than `RedoOverCommitLimit` seconds, and this occurs `RedoOverCommitLimit` times or more, the transactions contained within the redo log are aborted. Any operations left uncommitted as a result are either aborted or re-tried, according to the value of `DefaultOperationRedoProblemAction`.

    For more information, see Redo log over-commit handling

- **INFORMATION_SCHEMA improvements.**   Beginning with MySQL Cluster NDB 7.1.11, Beginning with MySQL Cluster NDB 7.0.22, `INFORMATION_SCHEMA` provides disk usage information for MySQL Cluster Disk Data tables. Previously, `INFORMATION_SCHEMA.TABLES` showed only the space usage for the in-memory data part of the table. Now, it also shows the space allocated for and used by the disk_part data of that table as well.

    In addition, the `INFORMATION_SCHEMA.PARTITIONS` table (which did not show any statistics for `NDB` tables) now shows correct values in this table's `TABLE_ROWS`, `AVG_ROW_LENGTH`, `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `DATA_FREE` columns, for each partition.

- **ndb_restore attribute demotion.**   Beginning with MySQL Cluster NDB 7.1.11, it is possible to enable attribute demotion when restoring a MySQL Cluster from a native backup running `ndb_restore` with a new `--lossy-conversions` option.

  In general,the rules governing demotion are the same as for MySQL replication, although there are some exceptions that you may need to take into account being employing this option. See Replication of Columns Having Different Data Types, for information about type conversions currently supported by attribute promotion and demotion in MySQL Cluster.

- **Improved multi-threaded order index building.**   Previously, it was not possible to enable multi-threaded building of ordered indexes during initial restarts. In MySQL Cluster NDB 7.1.11, this can now be done, using the new `TwoPassInitialNodeRestartCopy` data node configuration parameter.

- **Configuration version information in ndbinfo.nodes.**   You can see which version or versions of the MySQL Cluster configuration file are in effect on the data nodes by checking the `config_generation` column which is added to the `nodes` table in MySQL Cluster NDB 7.1.13.

- **Configuration version information in ndbinfo.nodes.**   You can see which version or versions of the MySQL Cluster configuration file are in effect on the data nodes by checking the `config_generation` column which is added to the `nodes` table in MySQL Cluster NDB 7.1.13.

- **Improvements in adding data nodes online.**   Begining with MySQL Cluster NDB 7.0.24, it is possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` option. This can be done by setting `Nodegroup = 65536` in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. The amount of time the cluster waits before doing this can be controlled using the `StartNoNodeGroupTimeout` data node configuration parameter.

- **Unique key updates in replication.**   It is possible in MySQL Cluster NDB 7.1.14 and later to employ operations that update unique keys when replicating `NDB` tables. Previously this could lead to duplicate key errors when trying to execute the binary log (due to the fact that row events in the binary log were ordered according to the partitioning of the base table, and could differ in order within the epoch for that in which they were executed).

  > **Important**
  >
  > Master and slave tables must both be using the `NDB` storage engine for this to work.

- Starting with MySQL Cluster NDB 7.1.17, the NDB kernel implements a number of statistical counters relating to actions performed by or affecting `Ndb` objects. Such events include starting, closing, and aborting transactions; operations using primary keys or unique keys; table, range, and pruned scans; blocking of threads by incompleted operations; and data and events sent and received by MySQL Cluster nodes. NDB API statistics counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. A MySQL Server running as an SQL node in the cluster can access the values of these counters as system status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in the `INFORMATION_SCHEMA` database. By comparing the values of these status variables before and after the execution of statements affecting `NDB` tables, you can observe the corresponding actions taken on the NDB API level. This can be highly useful when monitoring and tuning MySQL Cluster.

  For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables". See also MySQL Cluster Status Variables, for information about the individual status variables.

- **Version 2 binary log row events.**   New versions of the `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` events have been implemented in MySQL Cluster NDB 7.1.16, extending them with

additional information intended to support future enhancements; these are referred to as "Version 2" binary log events.

Version 2 log events are not backward compatible, and cannot be read by older slaves. A new `mysqld` option `--log-bin-use-v1-row-events` can be employed to force use of Version 1 events when writing the binary log. This can be used during upgrades to make a newer `mysqld` generate Version 1 binary log row events that can be read by older slaves.

- **Circular replication: Primary wins first conflict detection.** Two new conflict detection functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` can be useful in "active-active" circular replication scenarios with two MySQL Clusters. For each case, we designate one cluster as primary and one as secondary, and implement a "primary always wins" rule for determining whether to accept conflicting changes. When using `NDB$EPOCH()`, conflicting rows on the secondary are realigned with those on the primary; when using `NDB$EPOCH_TRANS()`, it is transactions containing rows in conflict (and any transactions which depend on them) on the secondary that are realigned.

  When using `NDB$EPOCH_TRANS()` as the conflict detection function, the binary log must be written using Version 2 binary logging row events; that is, the `mysqld` processes on both the primary and the secondary must be started with `--log-bin-use-v1-row-events=0`. In addition, the secondary's binary log must include transaction IDs for all rows, that is, by setting `--ndb-log-transaction-id=1`.

  You can monitor conflict detection and resolution performed using these functions by reading a number of related server status variables, including `Ndb_conflict_fn_epoch`, `Ndb_conflict_fn_epoch_trans`, and `Ndb_conflict_trans_row_conflict_count` (among others). See MySQL Cluster Status Variables.

  For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- **Fail-fast data node capability.** Beginning with MySQL Cluster NDB 7.1.17, it is possible to enable fail-fast behavior for data nodes by enabling the `CrashOnCorruptedTuple` configuration parameter introduced in this version (disabled by default). Doing so causes data nodes to fail whenever they detect a corrupted tuple.

- **Rows per partition limit removed.** Previously it was possible to store a maximum of 46137488 rows in a single MySQL Cluster partition—that is, per data node. Beginning with MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25, this limitation has been lifted, and there is no longer any practical upper limit to this number. (Bug #13844405, Bug #14000373)

MySQL Cluster NDB 7.1 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex MySQL Cluster management tasks. See MySQL™ Cluster Manager 1.3.6 User Manual, for more information.

17.1.4.3 What is New in MySQL Cluster NDB 7.0

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 7.0. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 7.0, see http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-7-0.html.

> **Important**
>
> Early development versions of MySQL Cluster NDB 7.0 were known as "MySQL Cluster NDB 6.4", and the first four releases in this series were identified as MySQL Cluster NDB 6.4.0 through 6.4.3. Any information relating to these MySQL Cluster NDB 6.4.x releases appearing in this documentation apply to MySQL Cluster NDB 7.0.

> MySQL Cluster NDB 7.0.4 is the fifth MySQL Cluster NDB 7.0 release; it is the successor to MySQL Cluster NDB 6.4.3.

- **MySQL Cluster on Windows (alpha).**   MySQL Cluster NDB 7.0 is available on an experimental basis for Windows operating systems (for production use on Windows, you should use MySQL Cluster NDB 7.1.3 or later). Features and behavior comparable to those found on platforms that are already supported —such as Linux and Solaris—are planned for MySQL Cluster on Windows. In MySQL Cluster NDB 7.0, you must build from source (Windows binaries are available for MySQL Cluster NDB 7.1 releases). To enable MySQL Cluster support on Windows when building from source, you must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option. For more information, see Section 2.11.7, "Installing MySQL from Source on Windows".

- **Ability to add nodes and node groups online.**   Beginning with MySQL Cluster NDB 6.4.0, it is possible to add new node groups (and thus new data nodes) to a running MySQL Cluster without shutting down and reloading the cluster. As part of enabling this feature, a new command `CREATE NODEGROUP` has been added to the cluster management client and the functionality of the `ALTER ONLINE TABLE ... REORGANIZE PARTITION` SQL statement has been extended. For more information, see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online".

- **Data node multi-threading support.**   Beginning with MySQL Cluster NDB 6.4.0, a multi-threaded version of the data node daemon, named `ndbmtd`, is available for use on data node hosts with multiple CPU cores. This binary is built automatically when compiling with MySQL Cluster support; no additional options other than those needed to provide MySQL Cluster support are needed when configuring the build. In most respects, `ndbmtd` functions in the same way as `ndbd`, and can use the same command-line options and configuration parameters. In addition, the new `MaxNoOfExecutionThreads` configuration parameter can be used to determine the number of data node process threads for `ndbmtd`. For more information, see Section 17.4.3, "`ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)".

> **Note**
>
> Disk Data tables are not yet supported for use with `ndbmtd`.

- **Configuration cache.**   Formerly, MySQL Cluster configuration was stateless—that is, configuration information was reloaded from the cluster's global configuration file (usually `config.ini`) each time `ndb_mgmd` was started. Beginning with MySQL Cluster NDB 6.4.0, the cluster's configuration is cached internally, and the global configuration file is no longer automatically re-read when the management server is restarted. This behavior can be controlled using the management server options `--configdir`, `--initial`, and `--reload`. In MySQL Cluster NDB 7.0.15 and later, the configuration cache can be disabled using the `--config-cache` option. For more information about these changes, see Section 17.3.3, "MySQL Cluster Configuration Files". For more information about the new management server options, see Section 17.4.4, "`ndb_mgmd` — The MySQL Cluster Management Server Daemon".

- **Detection of NDB API client connection errors.**   In MySQL Cluster NDB 7.0 (6.4.0 and later releases), the NDB API's `Ndb_cluster_connection` class adds the `get_latest_error()` and `get_latest_error_msg()` methods for catching and diagnosing problems with NDB API client connections.

- **Snapshot options for backups.**   Beginning with MySQL Cluster NDB 6.4.0, you can determine when performing a cluster backup whether the backup matches the state of the data when the backup was started or when it was completed, using the new options `SNAPSHOTSTART` and `SNAPSHOTEND` for the management client's `START BACKUP` command. See Section 17.5.3.2, "Using The MySQL Cluster Management Client to Create a Backup", for more information.

- **Dynamic NDB transporter send buffer memory allocation.**   Previously, the NDB kernel used a fixed-size send buffer for every data node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused. Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. This change is reflected by the addition of the configuration parameters `TotalSendBufferMemory`, `ReservedSendBufferMemory`, and `OverLoadLimit`, as well as a change in how the existing `SendBufferMemory` configuration parameter is used. For more information, see Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters".

- **Robust DDL operations.**   Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are protected from data node failures; in the event of a data node failure, such operations are now rolled back gracefully. Previously, if a data node failed while trying to perform a DDL operation, the MySQL Cluster data dictionary became locked and no further DDL statements could be executed without restarting the cluster.

- **IPv6 support in MySQL Cluster Replication.**   Beginning with MySQL Cluster NDB 6.4.1, IPv6 networking is supported between MySQL Cluster SQL nodes, which makes it possible to replicate between instances of MySQL Cluster using IPv6 addresses. However, IPv6 is supported only for direct connections between MySQL servers; all connections *within* an individual MySQL Cluster must use IPv4. For more information, see Section 17.6.3, "Known Issues in MySQL Cluster Replication".

- **Restoring specific databases, tables, or columns from a MySQL Cluster backup.**   It is now possible to exercise more fine-grained control when restoring a MySQL Cluster from backup using `ndb_restore`. Beginning with MySQL Cluster NDB 6.4.3, you can choose to restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. Beginning with MySQL Cluster NDB 7.0.7, it is also possible to restore to a table having fewer columns than the original using the `--exclude-missing-columns` option. For more information about all of these options, see Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup".

- **Improved Disk Data file system configuration.**   As of MySQL Cluster NDB 6.4.3, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node file systems to improve Disk Data performance. For more information, see Disk Data file system parameters.

- **Automatic creation of Disk Data log file groups and tablespaces.**   Beginning with MySQL Cluster NDB 6.4.3, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see *Disk Data object creation parameters*.

- **Improved internal message passing and record handling.**   MySQL Cluster NDB 7.0 contains 2 changes that optimize the use of network connections by addressing the size and number of messages passed between data nodes, and between data nodes and API nodes, which can increase MySQL Cluster and application performance:

  - **Packed reads.**   Formerly, each read request signal contained a list of columns to be retrieved, each of these column identifiers using 4 bytes within the message. This meant that the message size increased as the number of columns being fetched increased. In addition, in the response from the

data node, each column result was packed to a 4-byte boundary, which resulted in wasted space. In MySQL Cluster NDB 7.0, messaging for read operations is optimized in both directions, using a bitmap in the read request to specify the columns to be fetched. Where many fields are requested, this can result in a significant message size reduction as compared with the old method. In addition, the 4-byte packing in responses is no longer used, which means that smaller fields consume less space.

- **Long signal transactions.**   This enhancement reduces the number of messages and signals that are sent to data nodes for complex requests. Prior to MySQL Cluster NDB 7.0, there was a 100 byte limit on the size of the request signal, which meant that complex requests had to be split up between multiple messages prior to transmission, then reassembled on the receiving end. In addition to actual payload data, each message required its own operating system and protocol overhead such as header information. This often wasted network bandwidth and data node CPU. The maximum size of the message is now 32 KB, which is sufficient to accommodate most queries.

Both of these optimizations are internal to the NDB API, and so is transparent to applications; this is true whether an application uses the NDB API directly or does so indirectly through an SQL node.

- **Configuration parameter data dumps.**   Starting with MySQL Cluster NDB 7.0.6, the `ndb_config` utility supports a `--configinfo` option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters' default and permitted values, and the sections of the `config.ini` file in which the parameters apply. An additional `--xml` switch causes `ndb_config` to use XML rather than plain text output. Using `ndb_config --configinfo` or `ndb_config --configinfo --xml` requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see Section 17.4.7, "`ndb_config` — Extract MySQL Cluster Configuration Information".

- **Per-table reporting of free space on disk.**   The `INFORMATION_SCHEMA.FILES` table shows information about used and free space in MySQL Cluster Disk Data data files, but this information is not applicable to individual tables. In MySQL Cluster NDB 7.0.8 and later, the `ndb_desc` utility provides two additional columns in its output that show the amount of space allocated on disk for a given `NDB` table as well the amount of space that remains available for additional storage of disk-based column data for that table. For more information, see Section 17.4.10, "`ndb_desc` — Describe NDB Tables".

- **Improved restart times.**   Optimizations in redo log handling and other file system operations introduced in MySQL Cluster NDB 7.0.9 have the potential to reduce considerably the time required for restarts. While actual performance benefits observed in production setups will naturally vary depending on database size, hardware, and other conditions, our own preliminary testing has shown that these improvements can yield startup times that are faster than those typical of previous MySQL Cluster NDB 7.0 releases by a factor of 50 or more.

- **Native support for default column values.**   Starting with MySQL Cluster NDB 7.0.15, default values for table columns are stored in the NDB kernel rather than by the MySQL server as was done previously. This means that inserts on tables having column value defaults can be smaller and faster than before, because less data must be sent from SQL nodes to `NDBCLUSTER`.

Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.0.15 and later; however, they do not support native default values until they are upgraded. You can upgrade a table with non-native default values to support native default values using an offline `ALTER TABLE` statement.

- **--nowait-nodes option for management servers.**   Starting with MySQL Cluster NDB 7.0.10, it is possible to configure a cluster with two management servers, but to start the cluster using only one of them by starting the management node daemon with the `--nowait-nodes` option. The other management server can then be started at a later time to join the running MySQL Cluster.

- **Increased flexibility in online upgrade procedure.** Previously, when performing an upgrade of a running MySQL cluster, the order in which the types of cluster nodes had to be upgraded was very strict. However, beginning with MySQL Cluster NDB 7.0.10, MySQL Cluster supports online upgrading of API nodes (including MySQL servers running as SQL nodes) online upgrading management nodes, data nodes, or both.

  > **Important**
  >
  > Before attempting to use this new upgrade functionality, see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster", for additional information, especially if you are planning an online upgrade to MySQL Cluster NDB 7.0 from MySQL Cluster NDB 6.3.

- **New CHANGE MASTER TO option for circular replication.** Beginning with MySQL Cluster NDB 7.0.11, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

  See Section 13.4.2.1, "CHANGE MASTER TO Syntax", as well as Section 13.7.5.36, "SHOW SLAVE STATUS Syntax", for more information.

- **New replication conflict resolution strategy.** Beginning with MySQL Cluster NDB 7.0.11, the function `NDB$MAX_DELETE_WIN()` is available to implement "greatest timestamp, delete wins" conflict resolution. See NDB$MAX_DELETE_WIN(column_name), for more information.

- **Improved lock handling for primary key lookups on BLOB tables.** A MySQL Cluster table stores all but the first 256 bytes of any `BLOB` or `TEXT` column values in a separate `BLOB` table; when executing queries against such tables, a shared lock is obtained. Prior to MySQL Cluster NDB 7.0.12, when the query used a primary key lookup and took place within a transaction, the lock was held for the duration of the transaction, even after no more data was being read from the `NDB` table. Now in such cases, the lock is released when all `BLOB` data associated with the table has been read. (Bug #49190)

  > **Note**
  >
  > A shared lock is also taken for unique key lookups; it is still the case that this lock is held for the duration of the transaction.

- **Heartbeat thread policy and priority.** Beginning with MySQL Cluster NDB 7.0.13, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

- **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 7.0.13, the `--blob-info` option causes this program to include partition information for `BLOB` tables in its output. Beginning with MySQL Cluster NDB 7.0.14, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` option.

  Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 7.0.14.

- **Replication attribute promotion and demotion.** Beginning with MySQL Cluster NDB 7.0.14, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information, see Attribute promotion and demotion (MySQL Cluster).

- **Incompatible change in NDB API event reporting.**   Beginning with MySQL Cluster NDB 7.0.15, DDL events are no longer reported on `Event` objects by default. Instead such event reporting must be enabled explicitly using the `Event::setReport()` method. For more information, see Event::setReport(), and The Event::EventReport Type.

- **Number of table attributes.**   Beginning with MySQL Cluster NDB 7.0.15, the maximum number of attributes (columns plus indexes) per table has been increased from 128 to 512.

- **Heartbeat ordering.**   Beginning with MySQL Cluster NDB 7.0.16, it is possible to set a specific order for transmission of heartbeats between data nodes, using the `HeartbeatOrder` data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).

- **Relaxed ndb_restore column comparison rules.**   When restoring data, ndb_restore compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 7.0.16, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:

  - `COLUMN_FORMAT` setting (`FIXED`, `DYNAMIC`, or `DEFAULT`)

  - `STORAGE` setting (`MEMORY` or `DISK`)

  - The default value

  - The distribution key

  In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.

- **Storage of user data in anyValue.**   When writing NDB events to the binary log, MySQL Cluster uses `OperationOptions::anyValue` to store the server ID. Beginning with MySQL Cluster NDB 7.0.17, it is possible to store user data from an NDB API application in part of the `anyValue` when `mysqld` has been started with the `--server-id-bits` option set to a nondefault value. Also beginning with MySQL Cluster NDB 7.0.17, it is possible to view this data in the output of mysqlbinlog, for which its own `--server-id-bits` option is added.

- **--add-drop-trigger option for mysqldump.**   Beginning with MySQL Cluster NDB 7.0.19, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.

- **Forcing node shutdown and restart.**   In MySQL Cluster NDB 7.0.19 and later, it is possible using the `ndb_mgm` management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster. In the management client, this is implemented through the addition of the `-f` (force) option to the `STOP` and `RESTART` commands. For more information, see Section 17.5.2, "Commands in the MySQL Cluster Management Client". The MGM API also adds two new methods for forcing such a node shutdown or restart; see ndb_mgm_stop4(), and ndb_mgm_restart4(), for more information about these methods.

- **TimeBetweenEpochsTimeout and GCP stop control.**   Beginning with MySQL Cluster NDB 7.0.21, it is possible to disable GCP stops by setting `TimeBetweenEpochsTimeout` to 0. In addition, a warning is written to the cluster log whenever the time required for a GCP save exceeds 60 seconds or the time required for a GCP commit exceeds 10 seconds. This warning includes a report of the current value of `TimeBetweenEpochsTimeout`. For more information, see Disk Data and GCP Stop errors.

- **Skipping corrupted tables in NDB native backups.**   Beginning with MySQL Cluster NDB 7.0.21, you can cause `ndb_restore` to ignore tables that are corrupted due to missing blob parts tables by using the `--skip-broken-objects` option. When this option is used, such tables are skipped, and the restoration of any remaining uncorrupted tables in the backup continues.

- **BLOB read and write batching.**   Beginning with MySQL Cluster NDB 7.0.21, it possible to control batching of `BLOB` read and write operations. For SQL nodes, this can be done using the `--ndb-blob-read-batch-bytes` and `--ndb-blob-write-batch-bytes` options for `mysqld`. In NDB API applications, you can control batching of `BLOB` reads and writes using the `NdbTransaction` methods `setMaxPendingBlobReadBytes()`, `getMaxPendingBlobReadBytes()`, `setMaxPendingBlobWriteBytes()`, and `getMaxPendingBlobWriteBytes()`.

- **Restoring from a NDB native backup to a differently-named database.**   MySQL Cluster NDB 7.0.22 adds a new `--rewrite-database` option to `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup. The option can be used multiple times, and it is possible to restore from more than one source database in the backup to a single target database (although no protection against table or other object name collision is provided).

  See Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup", for more information.

- **INFORMATION_SCHEMA inprovements.**   Beginning with MySQL Cluster NDB 7.0.22, `INFORMATION_SCHEMA` provides disk usage information for MySQL Cluster Disk Data tables. Previously, `INFORMATION_SCHEMA.TABLES` showed only the space usage for the in-memory data part of the table. Now, it also shows the space allocated for and used by the disk_part data of that table as well.

  In addition, the `INFORMATION_SCHEMA.PARTITIONS` table (which did not show any statistics for `NDB` tables) now shows correct values in this table's `TABLE_ROWS`, `AVG_ROW_LENGTH`, `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `DATA_FREE` columns, for each partition.

- **Configuration version information in ndbinfo.nodes.**   You can see which version or versions of the MySQL Cluster configuration file are in effect on the data nodes by checking the `config_generation` column which is added to the `nodes` table in MySQL Cluster NDB 7.0.24.

- **Improvements in adding data nodes online.**   Beginning with MySQL Cluster NDB 7.0.24, it is possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` option. This can be done by setting `Nodegroup = 65536` in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. The amount of time the cluster waits before doing this can be controlled using the `StartNoNodeGroupTimeout` data node configuration parameter.

- **Unique key updates in replication.**   It is possible in MySQL Cluster NDB 7.0.25 and later to employ operations that update unique keys when replicating `NDB` tables. Previously this could lead to duplicate key errors when trying to execute the binary log (due to the fact that row events in the binary log were ordered according to the partitioning of the base table, and could differ in order within the epoch for that in which they were executed).

  > **⚠ Important**
  >
  > Master and slave tables must both be using the `NDB` storage engine for this to work.

- Starting with MySQL Cluster NDB 7.0.22, the NDB kernel implements a number of statistical counters relating to actions performed by or affecting `Ndb` objects. Such events include starting, closing, and aborting transactions; operations using primary keys or unique keys; table, range, and pruned scans; blocking of threads by incompleted operations; and data and events sent and received by MySQL Cluster nodes. NDB API statistics counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. A MySQL Server running as an SQL node in the cluster can access the values of these counters as system status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in the `INFORMATION_SCHEMA` database. By comparing the values of these status variables before and after the execution of statements affecting `NDB` tables, you can observe the corresponding actions taken on the NDB API level. This can be highly useful when monitoring and tuning MySQL Cluster.

  For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables". See also MySQL Cluster Status Variables, for information about the individual status variables.

- **Version 2 binary log row events.** New versions of the `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` events have been implemented in MySQL Cluster NDB 7.0.27, extending them with additional information intended to support future enhancements; these are referred to as "Version 2" binary log events.

  Version 2 log events are not backward compatible, and cannot be read by older slaves. A new `mysqld` option `--log-bin-use-v1-row-events` can be employed to force use of Version 1 events when writing the binary log. This can be used during upgrades to make a newer `mysqld` generate Version 1 binary log row events that can be read by older slaves.

- **Fail-fast data node capability.** Beginning with MySQL Cluster NDB 7.0.28, it is possible to enable fail-fast behavior for data nodes by enabling the `CrashOnCorruptedTuple` configuration parameter introduced in this version (disabled by default). Doing so causes data nodes to fail whenever they detect a corrupted tuple.

- **Rows per partition limit removed.** Previously it was possible to store a maximum of 46137488 rows in a single MySQL Cluster partition—that is, per data node. Beginning with MySQL Cluster NDB 7.0.36, this limitation has been lifted, and there is no longer any practical upper limit to this number.

17.1.4.4 What is New in MySQL Cluster NDB 6.3

The following list provides an overview of significant feature additions and changes first made in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.3, see http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-6-3.html.

- **Conflict detection and resolution.** It is now possible to detect and resolve conflicts that arise in multi-master replication scenarios, such as circular replication, when different masters may try to update the same row on the slave with different data. Both "greatest timestamp wins" and "same timestamp wins" scenarios are supported. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- **Recovery of one master, many slaves replication setups.** Recovery of multi-way replication setups ("one master, many slaves") is now supported using the `--ndb-log-orig` server option and changes in the `mysql.ndb_binlog_index` table. See Section 17.6.4, "MySQL Cluster Replication Schema and Tables", for more information.

- **Enhanced selection options for transaction coordinator.** New values and behaviors are introduced for `--ndb_optimized_node_selection`, enabling greater flexibility when an SQL node chooses a transaction coordinator. For more information, see the description of `ndb_optimized_node_selection` in MySQL Cluster System Variables.

- **Replication heartbeats.** Replication heartbeats facilitate the task of monitoring and detecting failures in master-slave connections in real time. This feature is implemented using a new `MASTER_HEARTBEAT_PERIOD = value` clause for the `CHANGE MASTER TO` statement and the addition of two status variables `Slave_heartbeat_period` and `Slave_received_heartbeats`. For more information, see Section 13.4.2.1, "CHANGE MASTER TO Syntax".

- **NDB thread locks.** It is possible to lock `NDB` execution threads and maintenance threads (such as file system and other operating system threads) to specific CPUs on multiprocessor data node hosts, and to leverage real-time scheduling.

- **Improved performance of updates using primary keys or unique keys.** The number of unnecessary reads when performing a primary key or unique key update has been greatly reduced. Since it is seldom necessary to read a record prior to an update, this can yield a considerable improvement in performance. In addition, primary key columns are no longer written to when not needed during update operations.

- **Batching improvements.** Support of batched `DELETE` and `UPDATE` operations has been significantly improved. Batching of `UPDATE WHERE...` and multiple `DELETE` operations is also now implemented.

- **Improved SQL statement performance metrics.** The `Ndb_execute_count` system status variable measures the number of round trips made by SQL statements to the `NDB` kernel, providing an improved metric for determining efficiency with which statements are executed. For more information, see *MySQL Cluster Status Variables:* `Ndb_execute_count`.

- **Compressed LCPs and backups.** Compressed local checkpoints and backups can save 50% or more of the disk space used by uncompressed LCPs and backups. These can be enabled using the two new data node configuration parameters `CompressedLCP` and `CompressedBackup`, respectively.

- **OPTIMIZE TABLE support with NDBCLUSTER tables.** `OPTIMIZE TABLE` is supported for dynamic columns of in-memory `NDB` tables. In such cases, it is no longer necessary to drop (and possibly to re-create) a table, or to perform a rolling restart, in order to recover memory from deleted rows for general re-use by Cluster. The performance of `OPTIMIZE` on Cluster tables can be tuned by adjusting the value of the `ndb_optimization_delay` system variable, which controls the number of milliseconds to wait between processing batches of rows by `OPTIMIZE TABLE`. In addition, `OPTIMIZE TABLE` on an `NDBCLUSTER` table can be interrupted by, for example, killing the SQL thread performing the `OPTIMIZE` operation.

- **Batching of transactions.** It is possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` to `1` or `ON`. To use this feature, `autocommit` must be set to `0` or `OFF`. Batch sizes can be controlled using the `--ndb-batch-size` option for `mysqld`. For additional information, see MySQL Server Options for MySQL Cluster, and MySQL Cluster System Variables.

- **Attribute promotion with ndb_restore.** It is possible using `ndb_restore` to restore data reliably from a column of a given type to a column that uses a "larger" type. This is sometimes referred to as *attribute promotion*. For example, MySQL Cluster backup data that originated in a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column. See Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup", for more information.

- **Parallel data node recovery.** Recovery of multiple data nodes can now be done in parallel, rather than sequentially. In other words, several data nodes can be restored concurrently, which can often result in much faster recovery times than when they are restored one at a time.

- **Increased local checkpoint efficiency.** Only 2 local checkpoints are stored, rather than 3, lowering disk space requirements and the size and number of redo log files.

- **NDBCLUSTER table persistence control.** Persistence of `NDB` tables can be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes `NDB` tables not to be checkpointed to disk; `ndb_table_temporary` does the same, and in addition, no schema files are created. See Section 17.3.2.5, "MySQL Cluster mysqld Option and Variable Reference".

- **Epoll support (Linux only).** *Epoll* is an improved method for handling file descriptors, which is more efficient than scanning to determine whether a file descriptor has data to be read. (The term *epoll* is specific to Linux and equivalent functionality is known by other names on other platforms such as Solaris and FreeBSD.) Currently, MySQL Cluster supports this functionality on Linux only.

- **Distribution awareness (SQL nodes).** In MySQL Cluster NDB 6.3, SQL nodes can take advantage of distribution awareness. Here we provide a brief example showing how to design a table to make a given class of queries distrubtion-aware. Suppose an `NDBCLUSTER` table `t1` has the following schema:

```
CREATE TABLE t1 (
    userid INT NOT NULL,
    serviceid INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    data VARCHAR(255)
)   ENGINE=NDBCLUSTER;
```

Suppose further that most of the queries to be used in our application test values of the `userid` column of this table. The form of such a query looks something like this:

```
SELECT columns FROM t1
    WHERE userid relation value;
```

In this query, `relation` represents some relational operator, such as `=`, `<`, `>`, and so on. Queries using `IN` and a list of values can also be used:

```
SELECT columns FROM t1
    WHERE userid IN value_list;
```

To make use of distribution awareness, we need to make the `userid` column part of the table's primary key, then explicitly partition the table with this column being used as the partitioning key. (Recall that for a partitioned table having one or more unique keys, all columns of the table's partitioning key must also be part of all of the unique keys—for more information and examples, see Section 18.5.1, "Partitioning Keys, Primary Keys, and Unique Keys".) In other words, the table schema should be equivalent to the following `CREATE TABLE` statement:

```
CREATE TABLE t1 (
    userid INT NOT NULL,
    serviceid INT NOT NULL AUTO_INCREMENT,
    data VARCHAR(255),
    PRIMARY KEY p (userid,serviceid)
)   ENGINE=NDBCLUSTER
    PARTITION BY KEY(userid);
```

When the table is partitioned in this way, all rows having the same `userid` value are found on the same node group, and the MySQL Server can immediately select the optimal node to use as the transaction coordinator.

- **Realtime extensions for multiple CPUs.** When running MySQL Cluster data nodes on hosts with multiple processors, the realtime extensions make it possible to give priority to the data node process and control on which CPU cores it should operate. This can be done using the data node configuration parameters `RealtimeScheduler`, `SchedulerExecutionTimer`, and `SchedulerSpinTimer`. Doing

so properly can significantly lower response times and make them much more predictable response. For more information about using these parameters, see Defining Data Nodes: Realtime Performance Parameters

- **Fully automatic database discovery.**   It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.

- **Detection of NDB API client connection errors.**   Beginning with MySQL Cluster NDB 6.3.20, the NDB API's `Ndb_cluster_connection` class adds the `get_latest_error()` and `get_latest_error_msg()` methods for catching and diagnosing problems with NDB API client connections.

- **Restoring specific databases, tables, or columns from a MySQL Cluster backup.**   It is now possible to exercise more fine-grained control when restoring a MySQL Cluster from backup using `ndb_restore`. Beginning with MySQL Cluster NDB 6.3.22, you can choose to restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. Beginning with MySQL Cluster NDB 6.3.26, it is also possible to restore to a table having fewer columns than the original using the `--exclude-missing-columns` option. For more information about all of these options, see Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup".

- **Improved Disk Data file system configuration.**   As of MySQL Cluster NDB 6.3.22, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node file systems to improve Disk Data performance. For more information, see Disk Data file system parameters.

- **Automatic creation of Disk Data log file groups and tablespaces.**   Beginning with MySQL Cluster NDB 6.3.22, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see *Disk Data object creation parameters*.

- **Configuration parameter data dumps.**   Starting with MySQL Cluster NDB 6.3.25, the `ndb_config` utility supports a `--configinfo` option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters' default and permitted values, and the sections of the `config.ini` file in which the parameters apply. An additional `--xml` switch causes `ndb_config` to use XML rather than plain text output. Using `ndb_config --configinfo` or `ndb_config --configinfo --xml` requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see Section 17.4.7, "`ndb_config` — Extract MySQL Cluster Configuration Information".

- **Per-table reporting of free space on disk.**   The `INFORMATION_SCHEMA.FILES` table shows information about used and free space in MySQL Cluster Disk Data data files, but this information is not applicable to individual tables. In MySQL Cluster NDB 6.3.27 and later, the `ndb_desc` utility provides two additional columns in its output that show the amount of space allocated on disk for a given `NDB` table as well the amount of space that remains available for additional storage of disk-based column data for that table. For more information, see Section 17.4.10, "`ndb_desc` — Describe NDB Tables".

- **Improved restart times.**   Optimizations in redo log handling and other file system operations introduced in MySQL Cluster NDB 6.3.28 have the potential to reduce considerably the time required for

restarts. While actual performance benefits observed in production setups will naturally vary depending on database size, hardware, and other conditions, our own preliminary testing has shown that these improvements can yield startup times that are faster than those typical of previous MySQL Cluster NDB 6.3 releases by a factor of 50 or more.

- **Increased flexibility in online upgrade procedure.**   Previously, when performing an upgrade of a running MySQL cluster, the order in which the types of cluster nodes had to be upgraded was very strict. However, beginning with MySQL Cluster NDB 6.3.29, MySQL Cluster supports online upgrading of API nodes (including MySQL servers running as SQL nodes) before upgrading management nodes, data nodes, or both.

  > **Important**
  >
  > Before attempting to use this new upgrade functionality, see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster", for additional information, especially if you are planning an online upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.

- **New replication conflict resolution strategy.**   Beginning with MySQL Cluster NDB 6.3.31, the function `NDB$MAX_DELETE_WIN()` is available to implement "greatest timestamp, delete wins" conflict resolution. See NDB$MAX_DELETE_WIN(column_name), for more information.

- **New CHANGE MASTER TO option for circular replication.**   Beginning with MySQL Cluster NDB 6.3.31, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

  See Section 13.4.2.1, "CHANGE MASTER TO Syntax", as well as Section 13.7.5.36, "SHOW SLAVE STATUS Syntax", for more information.

- **Heartbeat thread policy and priority.**   Beginning with MySQL Cluster NDB 6.3.32, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

- **Improved access to partitioning information.**   The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 6.3.32, the `--blob-info` option causes this program to include partition information for `BLOB` tables in its output. Beginning with MySQL Cluster NDB 6.3.33, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` option.

  Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 6.3.33.

- **Replication attribute promotion and demotion.**   Beginning with MySQL Cluster NDB 6.3.33, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

  The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

  For more information, see Attribute promotion and demotion (MySQL Cluster).

- **Incompatible change in NDB API event reporting.** Beginning with MySQL Cluster NDB 6.3.34, DDL events are no longer reported on `Event` objects by default. Instead such event reporting must be enabled explicitly using the `Event::setReport()` method. For more information, see Event::setReport(), and The Event::EventReport Type.

- **Heartbeat ordering.** Beginning with MySQL Cluster NDB 6.3.35, it is possible to set a specific order for transmission of heartbeats between data nodes, using the `HeartbeatOrder` data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).

- **Relaxed ndb_restore column comparison rules.** When restoring data, ndb_restore compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 6.3.35, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:

  - `COLUMN_FORMAT` setting (`FIXED`, `DYNAMIC`, or `DEFAULT`)

  - `STORAGE` setting (`MEMORY` or `DISK`)

  - The default value

  - The distribution key

  In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.

- **--add-drop-trigger option for mysqldump.** Beginning with MySQL Cluster NDB 6.3.38, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.

- **Skipping corrupted tables in NDB native backups.** Beginning with MySQL Cluster NDB 6.3.40, you can cause `ndb_restore` to ignore tables that are corrupted due to missing blob parts tables by using the `--skip-broken-objects` option. When this option is used, such tables are skipped, and the restoration of any remaining uncorrupted tables in the backup continues.

- **Restoring from a NDB native backup to a differently-named database.** MySQL Cluster NDB 6.3.41 adds a new `--rewrite-database` option to `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup. The option can be used multiple times, and it is possible to restore from more than one source database in the backup to a single target database (although no protection against table or other object name collision is provided).

  See Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup", for more information.

17.1.4.5 What is New in MySQL Cluster NDB 6.2

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.2. All of the changes in this list are also available in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.2, see http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-6-2.html.

- **Enhanced backup status reporting.** Backup status reporting has been improved, aided in part by the introduction of a `BackupReportFrequency` configuration parameter.

- **Multiple cluster connections per SQL node.**   A single MySQL server acting as a MySQL Cluster SQL node can employ multiple connections to the cluster using the `--ndb-cluster-connection-pool` startup option for `mysqld`. This option is described in *MySQL Cluster-Related Command Options for* `mysqld:` `--ndb-cluster-connection-pool` *option*.

- **New data access interface.**   The `NdbRecord` interface provides a new and simplified data handler for use in NDB API applications.

- **New reporting commands.**   The new management client `REPORT BackupStatus` and `REPORT MemoryUsage` commands provide better access to information about the status of MySQL Cluster backups and how much memory is being used by MySQL Cluster for data and index storage. See Section 17.5.2, "Commands in the MySQL Cluster Management Client", for more information about the `REPORT` commands. In addition, in-progress status reporting is provided by the `ndb_restore` utility; see Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup".

- **Improved memory allocation and configuration.**   Memory is now allocated by the `NDB` kernel to tables on a page-by-page basis, which significantly reduces the memory overhead required for maintaining `NDBCLUSTER` tables. In addition, the `MaxAllocate` configuration parameter now makes it possible to set the maximum size of the allocation unit used for table memory.

- **Choice of fixed-width or variable-width columns.**   You can control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by employing of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. In addition, the ability to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. For more information, see Section 13.1.17, "CREATE TABLE Syntax", and Section 13.1.7, "ALTER TABLE Syntax".

- **Controlling management client connections.**   The `--bind-address` cluster management server startup option makes it possible to restrict management client connections to `ndb_mgmd` to a single host (IP address or host name) and port, which can make MySQL Cluster management operations more secure. For more information about this option, see Section 17.4.4, "`ndb_mgmd` — The MySQL Cluster Management Server Daemon".

- **Micro-GCPs.**   Due to a change in the protocol for handling of global checkpoints (GCPs handled in this manner sometimes being referred to as "micro-GCPs"), it is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` and `TimeBetweenEpochsTimeout` configuration parameters. This improves the reliability and performance of MySQL Cluster Replication.

- **Core online schema change support.**   Support for the online `ALTER TABLE` operations `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` is available. When the `ONLINE` keyword is used, the `ALTER TABLE` is noncopying, which means that indexes do not have to be re-created, which provides these benefits:

  - Single user mode is no longer required for `ALTER TABLE` operations that can be performed online.

  - Transactions can continue during `ALTER TABLE` operations that can be performed online.

  - Tables being altered online are not locked against access by other SQL nodes.

    However, such tables are locked against other operations on the *same* SQL node for the duration of the `ALTER TABLE`. We are working to overcome this limitation in a future MySQL Cluster release.

  Online `CREATE INDEX` and `DROP INDEX` statements are also supported. Online changes can be suppressed using the `OFFLINE` key word. See Section 13.1.7.2, "ALTER TABLE Online Operations

in MySQL Cluster", Section 13.1.13, "CREATE INDEX Syntax", and Section 13.1.24, "DROP INDEX Syntax", for more detailed information.

- **mysql.ndb_binlog_index improvements.** More information has been added to the `mysql.ndb_binlog_index` table so that it is possible to determine which originating epochs have been applied inside an epoch. This is particularly useful for 3-way replication. See Section 17.6.4, "MySQL Cluster Replication Schema and Tables", for more information.

- **Epoch lag control.** The `MaxBufferedEpochs` data node configuration parameter provides a means to control the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect.

- **Fully automatic database discovery.** It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.

- **Multiple data node processes per host.**
  In earlier MySQL Cluster release series, we did not support MySQL Cluster deployments in production where more than one `ndbd` process was run on a single physical machine. However, beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host.

  > **Note**
  >
  > A multi-threaded version of `ndbd` tailored for use on hosts with multiple CPUs or cores was introduced in MySQL Cluster NDB 7.0. See Section 17.1.4.3, "What is New in MySQL Cluster NDB 7.0", and Section 17.4.3, "`ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)", for more information.

- **Improved Disk Data file system configuration.** As of MySQL Cluster NDB 6.2.17, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node file systems to improve Disk Data performance. For more information, see Disk Data file system parameters.

- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.2.17, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects.

- **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 6.2.19, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). This option also requires the use of the `--extra-partition-info` option.

  Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 6.2.19.

- **New CHANGE MASTER TO option for circular replication.** Beginning with MySQL Cluster NDB 6.2.19, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

See Section 13.4.2.1, "CHANGE MASTER TO Syntax", as well as Section 13.7.5.36, "SHOW SLAVE STATUS Syntax", for more information.

17.1.4.6 What is New in MySQL Cluster NDB 6.1

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.1. All of the changes in this list are also available in MySQL Cluster NDB 6.2 and 6.3 releases. For detailed information about all changes made in MySQL Cluster NDB 6.1, see http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-6-1.html.

- **Increased number of cluster nodes.** The maximum number of all nodes in a MySQL Cluster has been increased to 255. For more information, see Section 17.1.6.10, "Limitations Relating to Multiple MySQL Cluster Nodes".

- **Disabling arbitration.** It is now possible to disable arbitration by setting `ArbitrationRank=0` on all cluster management and SQL nodes. For more information, see *Defining the Management Server: `ArbitrationRank`* and *Defining SQL and Other API Nodes: `ArbitrationRank`*.

- **Additional DUMP commands.** New management client `DUMP` commands provide help with tracking transactions, scan operations, and locks. See Section 17.5.2, "Commands in the MySQL Cluster Management Client", and MySQL Cluster Management Client DUMP Commands, for more information.

- **Faster Disk Data backups.** Improvements in backups of Disk Data tables can yield a 10 to 15% increase in backup speed of Disk Data tables.

- **Batched slave updates.** Batching of updates on cluster replication slaves, enabled using the `--slave-allow-batching` option for `mysqld`, increases replication efficiency. For more information, see Section 17.6.6, "Starting MySQL Cluster Replication (Single Replication Channel)".

17.1.4.7 What is New in MySQL Cluster 5.1

A number of features for MySQL Cluster were implemented in MySQL 5.1 through MySQL 5.1.23, when support for MySQL Cluster was moved to MySQL Cluster NDB. All of the features in the following list are also available in all MySQL Cluster NDB (6.1 and later) releases.

- **Integration of MySQL Cluster into MySQL Replication.** MySQL Cluster Replication makes it possible to replicate from one MySQL Cluster to another. Updates on any SQL node (MySQL server) in the cluster acting as the master are replicated to the slave cluster; the state of the slave side remains consistent with the cluster acting as the master. This is sometimes referred to as *asynchronous replication* between clusters, providing *geographic redundancy*. It is also possible to replicate from a MySQL Cluster acting as the master to a standalone MySQL server acting as the slave, or from a standalone MySQL master server to a slave cluster; in either of these cases, the standalone MySQL server uses a storage engine other than `NDBCLUSTER`. Multi-master replication setups such as circular replication are also supported.

  See Section 17.6, "MySQL Cluster Replication".

- **Support for storage of rows on disk.** Storage of `NDBCLUSTER` table data on disk is now supported. Indexed columns, including the primary key hash index, must still be stored in RAM; however, all other columns can be stored on disk.

  See Section 17.5.12, "MySQL Cluster Disk Data Tables".

- **Variable-size columns.** In MySQL 5.0, an `NDBCLUSTER` table column defined as `VARCHAR(255)` used 260 bytes of storage independent of what was stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record is stored. This makes

possible a significant reduction in space requirements for such columns as compared to previous release series—by a factor of up to 5 in many cases.

- **User-defined partitioning.**   Users can define partitions based on columns that are part of the primary key. It is possible to partition `NDB` tables based on `KEY` and `LINEAR KEY` schemes. This feature is also available for many other MySQL storage engines, which support additional partitioning types that are not available with `NDBCLUSTER` tables.

  For additional general information about user-defined partitioning in MySQL 5.1, see Chapter 18, *Partitioning*. Specifics of partitioning types are discussed in Section 18.2, "Partitioning Types".

  The MySQL Server can also determine whether it is possible to "prune away" some of the partitions from the `WHERE` clause, which can greatly speed up some queries. See Section 18.4, "Partition Pruning", for information about designing tables and queries to take advantage of partition pruning.

- **Autodiscovery of table schema changes.**   In MySQL 5.0, it was necessary to issue a `FLUSH TABLES` statement or a "dummy" `SELECT` for new `NDBCLUSTER` tables or changes made to schemas of existing `NDBCLUSTER` tables on one SQL node to be visible on the cluster's other SQL nodes. In MySQL 5.1, this is no longer necessary; new Cluster tables and changes in the definitions of existing `NDBCLUSTER` tables made on one SQL node are immediately visible to all SQL nodes connected to the cluster.

  > **Note**
  >
  > When creating a new database, it is still necessary in MySQL 5.1 to issue a `CREATE DATABASE` or `CREATE SCHEMA` statement on each SQL node in the cluster.

- **Distribution awareness (NDB API).**   *Distribution awareness* is a mechanism by which the best data node is automatically selected to be queried for information. (Conceptually, it is similar in some ways to partition pruning (see Section 18.4, "Partition Pruning"). To take advantage of distribution awareness, you should do the following:

  1. Determine which table column is most likely to be used for finding matching records.

  2. Make this column part of the table's primary key.

  3. Explicitly partition the table by `KEY`, using this column as the table' partitioning key.

  Following these steps causes records with the same value for the partitioning column to be stored on the same partition (that is, in the same node group). When reading data, transactions are begun on the data node actually having the desired rows instead of this node being determined by the usual round-robin mechanism.

  > **Important**
  >
  > To see a measureable impact on performance, the cluster must have at least four data nodes, since, with only two data nodes, both data nodes have exactly the same data.

  Using distribution awareness can yield performance increase of as great as 45% when using four data nodes, and possibly more when using a greater number of data nodes.

  > **Note**
  >
  > In mainline MySQL 5.1 releases, distribution awareness was supported only when using the NDB API; support was added for SQL and API nodes in MySQL

> Cluster NDB 6.3 (see Section 17.1.4.4, "What is New in MySQL Cluster NDB 6.3", which includes an example showing how to create a table to take advantage of distribution awareness).

- **Online adding and dropping of indexes.**   For `ALTER TABLE` statements, `ADD INDEX` and `DROP INDEX` operations for dynamic (variable-width) columns on `NDB` tables are now performed as online operations (no table copying). This is also true for `CREATE INDEX` and `DROP INDEX`. As a result, these operations are now performed much more quickly than previously.

  For more information, see Section 13.1.7.2, "ALTER TABLE Online Operations in MySQL Cluster", Section 13.1.13, "CREATE INDEX Syntax", and Section 13.1.24, "DROP INDEX Syntax".

See Section 17.1.6.11, "Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x", for more information.

17.1.5 MySQL Server Using InnoDB Compared with MySQL Cluster

MySQL Server offers a number of choices in storage engines. Since both `NDBCLUSTER` and `InnoDB` can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in MySQL Cluster. They see `NDB` as a possible alternative or upgrade to the default `InnoDB` storage engine in MySQL 5.5. While `NDB` and `InnoDB` share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for MySQL Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the `NDB` storage engine used by MySQL Cluster with `InnoDB` used in MySQL 5.1 and MySQL 5.5. The next few sections provide a technical comparison. In many instances, decisions about when and where to use MySQL Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for `NDB` as opposed to `InnoDB` backends.

While it is possible to use `InnoDB` tables with MySQL Cluster, such tables are not clustered. MySQL Cluster NDB 7.1 releases use a `mysqld` based on MySQL 5.1 which includes `InnoDB` 1.0; MySQL Cluster NDB 7.2.1 and later are based on MySQL Server 5.5, which includes support for `InnoDB` 1.1. It is also not possible to use programs or libraries from a MySQL Cluster NDB 6.x or MySQL Cluster NDB 7.x distribution with MySQL Server 5.1 or MySQL Server 5.5, or the reverse.

While it is also true that some types of common business applications can be run either on MySQL Cluster or on MySQL Server (most likely using the `InnoDB` storage engine), there are some important architectural and implementation differences. Section 17.1.5.1, "Differences Between the NDB and InnoDB Storage Engines", provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 17.1.5.2, "NDB and InnoDB Workloads". This in turn has an impact on the types of applications that better suited for use with `NDB` or `InnoDB`. See Section 17.1.5.3, "NDB and InnoDB Feature Usage Summary", for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the `NDB` and `MEMORY` storage engines, see When to Use MEMORY or MySQL Cluster.

See Chapter 14, *Storage Engines*, for additional information about MySQL storage engines.

17.1.5.1 Differences Between the NDB and InnoDB Storage Engines

The MySQL Cluster `NDB` storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from `InnoDB` in a number of ways. For those unaccustomed to

working with `NDB`, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, joins, and other characteristics. These are shown in the following table:

Feature	`InnoDB`	MySQL Cluster
MySQL Server Version	`InnoDB` 1.1: 5.5 `InnoDB` 1.0: 5.1	MySQL Cluster NDB 6.3, 7.0, 7.1: 5.1 MySQL Cluster NDB 7.2: 5.5 MySQL Cluster NDB 7.3: 5.6
`InnoDB` Availability	`InnoDB` 1.1 plugin	*NDB 6.3, 7.0*: `InnoDB` storage engine *NDB 7.1*: `InnoDB` 1.0 plugin support (MySQL Cluster NDB 7.1.9a and later) *NDB 7.2*: `InnoDB` 1.1 (MySQL Cluster NDB 7.2.1 and later)
Storage Limits	64TB	3TB (Practical upper limit based on 48 data nodes with 64GB RAM each; can be increased with disk-based data and BLOBs)
Foreign Keys	Yes	Prior to MySQL Cluster NDB 7.3: No. (Ignored, as with `MyISAM`) Available in MySQL Cluster NDB 7.3 and later.
Transactions	All standard types	`READ COMMITTED`
MVCC	Yes	No
Data Compression	Yes	No (MySQL Cluster checkpoint and backup files can be compressed)
Large Row Support (> 14K)	Supported for `VARBINARY`, `VARCHAR`, `BLOB`, and `TEXT` columns	Supported for `BLOB` and `TEXT` columns only (Using these types to store very large amounts of data can lower MySQL Cluster performance)
Replication Support	Asynchronous and semisynchronous replication using MySQL Replication	Automatic synchronous replication within a MySQL Cluster. Asynchronous replication between MySQL Clusters, using MySQL Replication
Scaleout for Read Operations	Yes (MySQL Replication)	Yes (Automatic partitioning in MySQL Cluster; MySQL Replication)

Feature	**InnoDB**	**MySQL Cluster**
Scaleout for Write Operations	Requires application-level partitioning (sharding)	Yes (Automatic partitioning in MySQL Cluster is transparent to applications)
High Availability (HA)	Requires additional software	Yes (Designed for 99.999% uptime)
Node Failure Recovery and Failover	Requires additional software	Automatic (Key element in MySQL Cluster architecture)
Time for Node Failure Recovery	30 seconds or longer	Typically < 1 second
Real-Time Performance	No	Yes
In-Memory Tables	No	Yes (Some data can optionally be stored on disk; both in-memory and disk data storage are durable)
NoSQL Access to Storage Engine	Native memcached interface in development (see the MySQL Dev Zone article *MySQL Cluster 7.2 (DMR2): NoSQL, Key/Value, Memcached*)	Yes Multiple APIs, including C++, HTTP/REST, Java and JPA (MySQL Cluster NDB 7.1 and later); Memcached (MySQL Cluster NDB 7.2 and later); Node.js under development (MySQL Cluster NDB 7.3)
Concurrent and Parallel Writes	Not supported	Up to 48 writers, optimized for concurrent writes
Conflict Detection and Resolution (Multiple Replication Masters)	No	Yes
Hash Indexes	No	Yes
Online Addition of Nodes	Read-only replicas using MySQL Replication	Yes (all node types)
Online Upgrades	No	Yes
Online Schema Modifications	No.	Yes.

17.1.5.2 NDB and InnoDB Workloads

MySQL Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, MySQL Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the `NDB` and `InnoDB` storage engines with regard to some common types of database-driven application workloads are shown in the following table::

Workload	**InnoDB**	**MySQL Cluster (NDB)**
High-Volume OLTP Applications	Yes	Yes

Workload	`InnoDB`	MySQL Cluster (`NDB`)
DSS Applications (data marts, analytics)	Yes	Limited (Join operations across OLTP datasets not exceeding 3TB in size)
Custom Applications	Yes	Yes
Packaged Applications	Yes	Limited (should be mostly primary key access). **Note** MySQL Cluster NDB 7.3 supports foreign keys.
In-Network Telecoms Applications (HLR, HSS, SDP)	No	Yes
Session Management and Caching	Yes	Yes
E-Commerce Applications	Yes	Yes
User Profile Management, AAA Protocol	Yes	Yes

17.1.5.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of `InnoDB` with `NDB`, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

Preferred application requirements for `InnoDB`	Preferred application requirements for `NDB`
• Foreign keys **Note** MySQL Cluster NDB 7.3 supports foreign keys. • Full table scans • Very large databases, rows, or transactions • Transactions other than `READ COMMITTED`	• Write scaling • 99.999% uptime • Online addition of nodes and online schema operations • Multiple SQL and NoSQL APIs (see MySQL Cluster APIs: Overview and Concepts) • Real-time performance • Limited use of `BLOB` columns

17.1.6 Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations in current releases of MySQL Cluster as compared with the features available when using the `MyISAM` and `InnoDB` storage engines. If you check the "Cluster" category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs in the following

categories under "MySQL Server:" in the MySQL bugs database at http://bugs.mysql.com, which we intend to correct in upcoming releases of MySQL Cluster:

• MySQL Cluster

• Cluster Direct API (NDBAPI)

• Cluster Disk Data

• Cluster Replication

• ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.7, "How to Report Bugs or Problems". If we do not plan to fix the problem in MySQL Cluster NDB 7.1, we will add it to the list.

See Section 17.1.6.11, "Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x" for a list of issues in MySQL Cluster in MySQL 5.0 that have been resolved in the current version.

> **Note**
>
> Limitations and other issues specific to MySQL Cluster Replication are described in Section 17.6.3, "Known Issues in MySQL Cluster Replication".

17.1.6.1 Noncompliance with SQL Syntax in MySQL Cluster

Some SQL statements relating to certain MySQL features produce errors when used with `NDB` tables, as described in the following list:

• **Temporary tables.**   Temporary tables are not supported. Trying either to create a temporary table that uses the `NDB` storage engine or to alter an existing temporary table to use `NDB` fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.

• **Indexes and keys in NDB tables.**   Keys and indexes on MySQL Cluster tables are subject to the following limitations:

  • **Column width.**   Attempting to create an index on an `NDB` table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.

  • **TEXT and BLOB columns.**   You cannot create indexes on `NDB` table columns that use any of the `TEXT` or `BLOB` data types.

  • **FULLTEXT indexes.**   The `NDB` storage engine does not support `FULLTEXT` indexes, which are possible for `MyISAM` tables only.

    However, you can create indexes on `VARCHAR` columns of `NDB` tables.

  • **USING HASH keys and NULL.**   Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.

  • **Prefixes.**   There are no prefix indexes; only entire columns can be indexed. (The size of an `NDB` column index is always the same as the width of the column in bytes, up to and including 3072 bytes,

as described earlier in this section. Also see Section 17.1.6.6, "Unsupported or Missing Features in MySQL Cluster", for additional information.)

- **BIT columns.** A `BIT` column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.

- **AUTO_INCREMENT columns.** Like other MySQL storage engines, the `NDB` storage engine can handle a maximum of one `AUTO_INCREMENT` column per table, and this column must be indexed. However, in the case of a MySQL Cluster table with no explicit primary key, an `AUTO_INCREMENT` column is automatically defined and used as a "hidden" primary key. For this reason, you cannot create an `NDB` table having an `AUTO_INCREMENT` column and no explicit primary key.

- **MySQL Cluster and geometry data types.**
  Geometry data types (`WKT` and `WKB`) are supported in `NDB` tables in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1). However, spatial indexes are not supported.

- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the `latin1` (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

  To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning for MySQL Cluster is restricted to [`LINEAR`] `KEY` partitioning. Beginning with MySQL 5.1.12, using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.

  It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see User-defined partitioning and the NDB storage engine (MySQL Cluster).

  Default partitioning scheme. As of MySQL 5.1.6, all MySQL Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the "hidden" primary key automatically created by the `NDBCLUSTER` storage engine is used instead. For additional discussion of these and related issues, see Section 18.2.4, "KEY Partitioning".

  Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error (Bug #40709):

  1. The table must have an explicit primary key.

  2. All columns listed in the table's partitioning expression must be part of the primary key.

  Exception. If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

  Maximum number of partitions for NDBCLUSTER tables. The maximum number of partitions that can defined for a `NDBCLUSTER` table when employing user-defined partitioning is 8 per node group. (See Section 17.1.2, "MySQL Cluster Nodes, Node Groups, Replicas, and Partitions", for more information about MySQL Cluster node groups.

  DROP PARTITION not supported. It is not possible to drop partitions from `NDB` tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—ADD

PARTITION, REORGANIZE PARTITION, and COALESCE PARTITION—are supported for Cluster tables, but use copying and so are not optimized. See Section 18.3.1, "Management of RANGE and LIST Partitions" and Section 13.1.7, "ALTER TABLE Syntax".

- **Row-based replication.**
  When using row-based replication with MySQL Cluster, binary logging cannot be disabled. That is, the NDB storage engine ignores the value of sql_log_bin. (Bug #16680)

17.1.6.2 Limits and Differences of MySQL Cluster from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

Memory usage and recovery.   Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A DELETE statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing a rolling restart of the cluster. See Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster".

  Beginning with MySQL Cluster NDB 6.3.7, this limitation can be overcome using OPTIMIZE TABLE. See Section 17.1.6.11, "Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x", for more information.

- A DROP TABLE or TRUNCATE TABLE operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

  > **Note**
  >
  > Recall that TRUNCATE TABLE drops and re-creates the table. See Section 13.1.34, "TRUNCATE TABLE Syntax".

- **Limits imposed by the cluster's configuration.**
  A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 17.3.3, "MySQL Cluster Configuration Files". Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (DataMemory and IndexMemory, respectively).

    DataMemory is allocated as 32KB pages. As each DataMemory page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

    See Section 17.3.3.6, "Defining MySQL Cluster Data Nodes", for more information.

  - The maximum number of operations that can be performed per transaction is set using the configuration parameters MaxNoOfConcurrentOperations and MaxNoOfLocalOperations.

    > **Note**
    >
    > Bulk loading, TRUNCATE TABLE, and ALTER TABLE are handled as special cases by running multiple transactions, and so are not subject to this limitation.

  - Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by MaxNoOfOrderedIndexes, and the maximum number of ordered indexes per table is 16.

- **Node and data object maximums.**   The following limits apply to numbers of cluster nodes and metadata objects:

  - The maximum number of data nodes is 48.

    A data node must have a node ID in the range of 1 to 48, inclusive. (Previous to MySQL Cluster NDB 6.1.1, management and API nodes were restricted to the range 1 to 63 inclusive as a node ID; starting with MySQL Cluster NDB 6.1.1, management and API nodes may use node IDs in the range 1 to 255, inclusive.)

  - Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63. Beginning with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster is 255. In either case, this number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

  - The maximum number of metadata objects in current versions of MySQL Cluster is 20320. This limit is hard-coded.

  See Section 17.1.6.11, "Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x", for more information.

17.1.6.3 Limits Relating to Transaction Handling in MySQL Cluster

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.**   The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) You should keep in mind that `NDB` implements `READ COMMITTED` on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

  Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe "before" values, "after" values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

  To ensure that a given transaction reads only before or after values, you can impose row locks using `SELECT ... LOCK IN SHARE MODE`. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

  - Increased frequency of lock wait timeout errors, and reduced concurrency

  - Increased transaction processing overhead due to reads requiring a commit phase

  - Possibility of exhausting the available number of concurrent locks, which is limited by `MaxNoOfConcurrentOperations`

  `NDB` uses `READ COMMITTED` for all reads unless a modifier such as `LOCK IN SHARE MODE` or `FOR UPDATE` is used. `LOCK IN SHARE MODE` causes shared row locks to be used; `FOR UPDATE` causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by `NDB` to ensure a self-consistent read; `BLOB` reads also employ extra locking for consistency.

  See Section 17.5.3.4, "MySQL Cluster Backup Troubleshooting", for information on how MySQL Cluster's implementation of transaction isolation level can affect backup and restoration of `NDB` databases.

- **Transactions and BLOB or TEXT columns.**   `NDBCLUSTER` stores only part of a column value that uses any of MySQL's `BLOB` or `TEXT` data types in the table visible to MySQL; the remainder of the `BLOB` or `TEXT` is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing `SELECT` statements on tables that contain columns of these types:

  1. For any `SELECT` from a MySQL Cluster table: If the `SELECT` includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

  2. Prior to MySQL Cluster NDB 7.0.12, for any `SELECT` which used a primary key lookup or unique key lookup to retrieve any columns that used any of the `BLOB` or `TEXT` data types and that was executed within a transaction, a shared read lock was held on the table for the duration of the transaction—that is, until the transaction was either committed or aborted.

     In MySQL Cluster NDB 7.0.12 and later, for primary key lookups, the lock is released as soon as all `BLOB` or `TEXT` data has been read. (Bug #49190) However, for unique key lookups, the shared lock continues to be held for the lifetime of the transaction.

     This issue does not occur for queries that use index or table scans, even against `NDB` tables having `BLOB` or `TEXT` columns.

     For example, consider the table `t` defined by the following `CREATE TABLE` statement:

     ```
     CREATE TABLE t (
         a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
         b INT NOT NULL,
         c INT NOT NULL,
         d TEXT,
         INDEX i(b),
         UNIQUE KEY u(c)
     ) ENGINE = NDB,
     ```

     Either of the following queries on `t` causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

     ```
     SELECT * FROM t WHERE a = 1;

     SELECT * FROM t WHERE c = 1;
     ```

     However, none of the four queries shown here causes a shared read lock:

     ```
     SELECT * FROM t WHERE b = 1;

     SELECT * FROM t WHERE d = '1';

     SELECT * FROM t;

     SELECT b,c WHERE a = 1;
     ```

     This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

     You can help minimize issues with shared read locks by avoiding queries that use unique key lookups (or primary key lookups in MySQL Cluster NDB 7.0.11 and earlier) that retrieve `BLOB` or

`TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

  This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.**
  As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is effected as described in the following list:

  - `TRUNCATE TABLE` is not transactional when used on `NDB` tables. If a `TRUNCATE TABLE` fails to empty the table, then it must be re-run until it is successful.

  - `DELETE FROM` (even with no `WHERE` clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to "chunk" the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE TABLE` instead.

  - **LOAD DATA statements.** `LOAD DATA INFILE` is not transactional when used on `NDB` tables.

    > ⚠️ **Important**
    >
    > When executing a `LOAD DATA INFILE` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

    `LOAD DATA FROM MASTER` is not supported in MySQL Cluster.

  - **ALTER TABLE and transactions.** When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

- **Transactions and the COUNT() function.** When using MySQL Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the slave. In other words, when performing on the master a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the slave may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the `NDB` storage engine. (See Bug #31321 for more information.)

17.1.6.4 MySQL Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `Temporary failure, distribution changed` and similar temporary errors.

- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

17.1.6.5 Limits Associated with Database Objects in MySQL Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Database and table names.**   When using the `NDB` storage engine, the maximum allowed length both for database names and for table names is 63 characters.

- **Table names containing special characters.**   `NDB` tables whose names contain characters other than letters, numbers, dashes, and underscores and which are created on one SQL node were not always discovered correctly by other SQL nodes. (Bug #31470)

  > **Note**
  >
  > This issue was fixed in MySQL 5.1.23, MySQL Cluster NDB 6.2.7, and MySQL Cluster NDB 6.3.4.

- **Number of database objects.**   The maximum number of *all* `NDB` database objects in a single MySQL Cluster—including databases, tables, and indexes—is limited to 20320.

- **Attributes per table.**   Prior to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the maximum number of attributes (that is, columns and indexes) per table is limited to 128.

  Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this limit is increased to 512.

- **Attributes per key.**   The maximum number of attributes per key is 32.

- **Row size.**   Prior to MySQL Cluster NDB 7.0, the maximum permitted size of any one row was 8052 bytes; in MySQL Cluster NDB 7.0 and later, this is 14000 bytes. Each `BLOB` or `TEXT` column contributes 256 + 8 = 264 bytes to this total.

- **BIT column storage per table.**   The maximum combined width for all `BIT` columns used in a given `NDB` table is 4096.

17.1.6.6 Unsupported or Missing Features in MySQL Cluster

A number of features supported by other storage engines are not supported for `NDB` tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by `NDB`, must be syntactically and otherwise valid.

- **Foreign key constraints.**   Prior to MySQL Cluster NDB 7.3, the foreign key construct is ignored, just as it is by `MyISAM` tables. Foreign keys are supported in MySQL Cluster NDB 7.3 and later.

- **Index prefixes.**   Prefixes on indexes are not supported for `NDB` tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is not created by `NDB`.

  A statement containing an index prefix, and creating or modifying an `NDB` table, must still be syntactically valid. For example, the following statement always fails with Error 1089 `Incorrect prefix key; the used key part isn't a string, the used length is longer than the key`

`part, or the storage engine doesn't support unique prefix keys`, regardless of storage engine:

```
CREATE TABLE t1 (
    c1 INT NOT NULL,
    c2 VARCHAR(100),
    INDEX i1 (c2(500))
);
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **OPTIMIZE operations.**   `OPTIMIZE` operations are not supported.

  Beginning with MySQL Cluster NDB 6.3.7, this limitation has been lifted. See Section 17.1.6.11, "Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x", for more information.

- **LOAD TABLE ... FROM MASTER.**   `LOAD TABLE FROM MASTER` is not supported.

- **Savepoints and rollbacks.**   Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.

- **Durability of commits.**   There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- **Replication.**   Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See Section 17.6, "MySQL Cluster Replication", for more information.

> **Note**
>
> See Section 17.1.6.3, "Limits Relating to Transaction Handling in MySQL Cluster", for more information relating to limitations on transaction handling in `NDB`.

17.1.6.7 Limitations Relating to Performance in MySQL Cluster

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.**   There are query performance issues due to sequential access to the `NDB` storage engine; it is also relatively more expensive to do many range scans than it is with either `MyISAM` or `InnoDB`.

- **Reliability of Records in range.**   The `Records in range` statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ `USE INDEX` or `FORCE INDEX` to alter the execution plan. See Section 8.9.3, "Index Hints", for more information on how to do this.

- **Unique hash indexes.**   Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.

17.1.6.8 Issues Exclusive to MySQL Cluster

The following are limitations specific to the `NDBCLUSTER` storage engine:

- **Machine architecture.**   All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node

that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.

- **Binary logging.**
  MySQL Cluster has the following limitations or restrictions with regard to binary logging:

  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.

  - MySQL Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.

  - Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:

    - `CREATE TABLE`

    - `ALTER TABLE`

    - `DROP TABLE`

    - `CREATE DATABASE` / `CREATE SCHEMA`

    - `DROP DATABASE` / `DROP SCHEMA`

    - `CREATE TABLESPACE`

    - `ALTER TABLESPACE`

    - `DROP TABLESPACE`

    - `CREATE LOGFILE GROUP`

    - `ALTER LOGFILE GROUP`

    - `DROP LOGFILE GROUP`

  See also Section 17.1.6.10, "Limitations Relating to Multiple MySQL Cluster Nodes".

17.1.6.9 Limitations Relating to MySQL Cluster Disk Data Storage

Disk Data object maximums and minimums.   Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: 2^{32} (4294967296)

- Maximum number of data files per tablespace: 2^{16} (65536)

- Maximum data file size: The theoretical limit is 64G; however, in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

  Since a MySQL Cluster Disk Data table can use at most 1 tablespace, this means that the theoretical upper limit to the amount of data (in bytes) that can be stored on disk by a single `NDB` table is 32G * 65536 = 2251799813685248, or approximately 2 petabytes.

- The theoretical maximum number of extents per tablespace data file is 2^{16} (65536); however, for practical purposes, the recommended maximum number of extents per data file is 2^{15} (32768).

  The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 13.1.18, "CREATE TABLESPACE Syntax", for more information.

Disk Data tables and diskless mode. Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is prohibited altogether. (Bug #20008)

17.1.6.10 Limitations Relating to Multiple MySQL Cluster Nodes

Multiple SQL nodes.
The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster "sees" this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)

Multiple management nodes.
When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.

- In MySQL Cluster NDB 7.0.7 and earlier, you must take extreme care to have the same configurations for all management servers; no special checks for consistency are performed.

  Beginning with MySQL Cluster NDB 7.0.8, a management server when first starting checks for any other management server in the same MySQL Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of a MySQL Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this MySQL Cluster. See Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster", for more information.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

> **Note**
>
> It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See Section 17.3.3.9, "MySQL Cluster TCP/IP Connections", for more information.

17.1.6.11 Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x

A number of limitations and related issues existing in earlier versions of MySQL Cluster have been resolved:

- **Variable-length column support.** The `NDBCLUSTER` storage engine now supports variable-length column types for in-memory tables.

Previously, for example, any Cluster table having one or more `VARCHAR` fields which contained only relatively small values, much more memory and disk space were required when using the `NDBCLUSTER` storage engine than would have been the case for the same table and data using the `MyISAM` engine. In other words, in the case of a `VARCHAR` column, such a column required the same amount of storage as a `CHAR` column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where storage requirements for variable-length column types such as `VARCHAR` and `BINARY` are comparable to those for these column types when used in `MyISAM` tables (see Section 11.7, "Data Type Storage Requirements").

> **Important**
>
> For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See Section 17.5.12, "MySQL Cluster Disk Data Tables".

- **Replication with MySQL Cluster.**   It is now possible to use MySQL replication with Cluster databases. For details, see Section 17.6, "MySQL Cluster Replication".

  Circular Replication.   Circular replication is also supported with MySQL Cluster, beginning with MySQL 5.1.18. See Section 17.6.10, "MySQL Cluster Replication: Multi-Master and Circular Replication".

- **auto_increment_increment and auto_increment_offset.**   The `auto_increment_increment` and `auto_increment_offset` server system variables are supported for Cluster replication beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster 6.3.2.

- **Database autodiscovery and online schema changes.**   Autodiscovery of databases is now supported for multiple MySQL servers accessing the same MySQL Cluster. Formerly, autodiscovery in MySQL Cluster 5.1 and MySQL Cluster NDB 6.x releases required that a given `mysqld` was already running and connected to the cluster at the time that the database was created on a different `mysqld`—in other words, when a `mysqld` process connected to the cluster after a database named *db_name* was created, it was necessary to issue a `CREATE DATABASE` *db_name* or `CREATE SCHEMA` *db_name* statement on the "new" MySQL server when it first accessed that MySQL Cluster. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.18, such a `CREATE` statement is no longer required. (Bug #39612)

  This also means that online schema changes in `NDB` tables are now possible. That is, the result of operations such as `ALTER TABLE` and `CREATE INDEX` performed on one SQL node in the cluster are now visible to the cluster's other SQL nodes without any additional action being taken.

- **Backup and restore between architectures.**   Beginning with MySQL 5.1.10, it is possible to perform a Cluster backup and restore between different architectures. Previously—for example—you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. (Bug #19255)

- **Character set directory.**   Beginning with MySQL 5.1.10, it is possible to install MySQL with Cluster support to a nondefault location and change the search path for font description files using either the `--basedir` or `--character-sets-dir` options. (Previously, `ndbd` in MySQL 5.1 searched only the default path—typically `/usr/local/mysql/share/mysql/charsets`—for character sets.)

- **Multiple management servers.**   In MySQL 5.1 (including all MySQL Cluster NDB 6.x and later versions), it is no longer necessary, when running multiple management servers, to restart all the cluster's data nodes to enable the management nodes to see one another.

  Also, when using multiple management servers and starting concurrently several API nodes (possibly including one or more SQL nodes) whose connection strings listed the management servers in different

order, it was possible for 2 API nodes to be assigned the same node ID. This issue is resolved in MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3. (Bug #42973)

If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.

- **Multiple data node processes per host.**   Beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host. (In MySQL Cluster NDB 6.1, MySQL 5.1, and earlier release series, we did not support production MySQL Cluster deployments in which more than one `ndbd` process was run on a single physical machine.)

  In addition, MySQL Cluster NDB 7.0 introduces support for multi-threaded data nodes (`ndbmtd`). See Section 17.1.4.3, "What is New in MySQL Cluster NDB 7.0", and Section 17.4.3, "`ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)", for more information.

- **Identifiers.**   Formerly (in MySQL 5.0 and earlier), database names, table names and attribute names could not be as long for `NDB` tables as tables using other storage engines, because attribute names were truncated internally. In MySQL 5.1 and later, names of MySQL Cluster databases, tables, and table columns follow the same rules regarding length as they do for any other storage engine.

- **Length of CREATE TABLE statements.**   `CREATE TABLE` statements may be no more than 4096 characters in length. *This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only*. (See Bug #17813)

- **IGNORE and REPLACE functionality.**   In MySQL 5.1.7 and earlier, `INSERT IGNORE`, `UPDATE IGNORE`, and `REPLACE` were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.

  This limitation was removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.1.8. (See Bug #17431.)

- **AUTO_INCREMENT columns.**   In MySQL 5.1.10 and earlier versions, the maximum number of tables having `AUTO_INCREMENT` columns—including those belonging to hidden primary keys—was 2048.

  This limitation was lifted in MySQL 5.1.11.

- **Maximum number of cluster nodes.**   Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

  Starting with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster is 255, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers. The total number of data nodes and management nodes beginning with this version is 63, of which up to 48 can be data nodes.

  > **Note**
  >
  > The limitation that a data node cannot have a node ID greater than 49 continues to apply.

- **Recovery of memory from deleted rows.**   Beginning with MySQL Cluster NDB 6.3.7, memory can be reclaimed from an `NDB` table for reuse with any `NDB` table by employing `OPTIMIZE TABLE`, subject to the following limitations:

  - Only in-memory tables are supported; the `OPTIMIZE TABLE` statement still has no effect on MySQL Cluster Disk Data tables.

- Only variable-length columns (such as those declared as `VARCHAR`, `TEXT`, or `BLOB`) are supported.

  However, you can force columns defined using fixed-length data types (such as `CHAR`) to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

  See Section 13.1.17, "CREATE TABLE Syntax", and Section 13.1.7, "ALTER TABLE Syntax", for information on these options.

  You can regulate the effects of `OPTIMIZE` on performance by adjusting the value of the global system variable `ndb_optimization_delay`, which sets the number of milliseconds to wait between batches of rows being processed by `OPTIMIZE`. The default value is 10 milliseconds. It is possible to set a lower value (to a minimum of `0`), but not recommended. The maximum is 100000 milliseconds (that is, 100 seconds).

- **Implicit Rollbacks.**   Prior to MySQL Cluster NDB 6.2.17 and MySQL Cluster NDB 6.3.19, MySQL Cluster did not automatically roll back a transaction that was aborted by a duplicate key or similar error, and subsequent statements raised `ERROR 1296 (HY000): Got error 4350 'Transaction already aborted' from NDBCLUSTER`. In such cases, it was necessary to issue an explicit `ROLLBACK` statement first, and then to retry the entire transaction.

  Beginning with MySQL Cluster NDB 6.2.17 and MySQL Cluster NDB 6.3.19, this limitation has been removed; now, an error which causes a transaction to be aborted generates an implicit rollback of the entire transaction. This is logged with the warning `Storage engine NDB does not support rollback for this statement. Transaction rolled back and must be restarted`. A statement subsequent to this starts a new transaction. (Bug #32656)

  > **Note**
  >
  > The `NDBCLUSTER` storage engine does not support partial transactions or partial rollbacks of transactions in any version of MySQL Cluster.

- **Number of tables.**   Previously, the maximum number of `NDBCLUSTER` tables in a single MySQL Cluster was 1792, but this is no longer the case in MySQL 5.1 and later MySQL Cluster releases. However, the number of tables is still included in the total maximum number of `NDBCLUSTER` database objects (20320). (See Section 17.1.6.5, "Limits Associated with Database Objects in MySQL Cluster".)

- **DDL operations.**   Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are protected from data node failures. Previously, if a data node failed while trying to perform one of these, the data dictionary became locked and no further DDL statements could be executed without restarting the cluster (Bug #36718).

- **Adding and dropping of data nodes.**   In MySQL Cluster NDB 6.3 and previous versions of MySQL Cluster, the online adding or dropping of data nodes was not possible; such operations required a complete shutdown and restart of the entire cluster. In MySQL Cluster NDB 7.0 (beginning with MySQL Cluster NDB 6.4.0) and later MySQL Cluster release series, it is possible to add new data nodes to a running MySQL Cluster by performing a rolling restart, so that the cluster and the data stored in it remain available to applications.

  When planning to increase the number of data nodes in the cluster online in MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1, you should be aware of and take into account the following issues:

  - New data nodes can be added online to a MySQL Cluster only as part of a new node group.

  - New data nodes can be added online, but cannot yet be dropped online. Reducing the number of data nodes still requires a system restart of the cluster.

- As in previous MySQL Cluster releases, it is not possible to change online either the number of replicas (`NoOfReplicas` configuration parameter) or the number of data nodes per node group. These changes require a system restart.

- Redistribution of existing cluster data using the new data nodes is not automatic; however, this can be accomplished using simple SQL statements in the `mysql` client or other MySQL client application once the nodes have been added. During this procedure, it is not possible to perform DDL operations, although DML operations can continue as normal.

  The distribution of new cluster data (that is, data stored in the cluster *after* the new nodes have been added) uses the new nodes without manual intervention.

  For more information, see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online".

- **Native support for default column values.**   Starting with MySQL Cluster NDB 7.1.0, default values for table columns are stored by `NDBCLUSTER`, rather than by the MySQL server as was previously the case. Because less data must be sent from an SQL node to the data nodes, inserts on tables having column value defaults can be performed more efficiently than before.

  Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.1.0 and later, although they do not support native default values and continue to use defaults supplied by the MySQL server until they are upgraded. This can be done by means of an offline `ALTER TABLE` statement.

  > **Important**
  >
  > You cannot set or change a table column's default value using an online `ALTER TABLE` operation

- **InnoDB plugin support.**   Previously, `InnoDB` support in MySQL Cluster was limited to the version built in to the MySQl Server. Beginning with MySQL Cluster NDB 7.1.9, MySQL Cluster also provides support for the `InnoDB` Plugin. See Section 17.2, "MySQL Cluster Installation and Upgrades", for information about enabling `InnoDB` storage engine and plugin support with MySQL Cluster.

- **Distribution of MySQL users and privileges.**   Previously, MySQL users and privileges created on one SQL node were unique to that SQL node, due to the fact that the MySQL grant tables were restricted to using the `MyISAM` storage engine. Beginning with MySQL Cluster NDB 7.2.0, it is possible, following installation of the MySQL Cluster software and setup of the desired users and privileges on one SQL node, to convert the grant tables to use `NDB` and thus to distribute the users and privileges across all SQL nodes connected to the cluster. You can do this by loading and making use of a set of stored procedures defined in an SQL script supplied with the MySQL Cluster distribution. For more information, see Section 17.5.14, "Distributed MySQL Privileges for MySQL Cluster".

- **Number of rows per partition.**   Previously, a single MySQL Cluster partition could hold a maximum of 46137488 rows. This limitation was removed in MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25. (Bug #13844405, Bug #14000373)

  If you are still using a previous MySQL Cluster release, you can work around this limitation by taking advantage of the fact that the number of partitions is the same as the number of data nodes in the cluster (see Section 17.1.2, "MySQL Cluster Nodes, Node Groups, Replicas, and Partitions"). This means that, by increasing the number of data nodes, you can increase the available space for storing data.

In MySQL Cluster NDB 7.0 and later, you can increase the number of data nodes in the cluster while the cluster remains in operation. See Section 17.5.13, "Adding MySQL Cluster Data Nodes Online", for more information.

It is also possible to increase the number of partitions for `NDB` tables by using explicit `KEY` or `LINEAR KEY` partitioning (see Section 18.2.4, "KEY Partitioning").

17.2 MySQL Cluster Installation and Upgrades

This section describes the basics for planning, installing, configuring, and running a MySQL Cluster. Whereas the examples in Section 17.3, "Configuration of MySQL Cluster NDB 6.1-7.1" provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the *minimum* requirements for availability and safeguarding of data.

For information about upgrading or downgrading a MySQL Cluster between release versions, see Section 17.2.7, "Upgrading and Downgrading MySQL Cluster".

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

Assumptions. The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

Node	IP Address
Management node (`mgmd`)	192.168.0.10
SQL node (`mysqld`)	192.168.0.20
Data node "A" (`ndbd`)	192.168.0.30
Data node "B" (`ndbd`)	192.168.0.40

This may be made clearer by the following diagram:

Figure 17.4 MySQL Cluster Multi-Computer Setup
Network addressing.   In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

Potential hosts file issues.   A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
#  ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost
```

```
#  ndb2 /etc/hosts:
127.0.0.1   ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
#  ndb1 /etc/hosts:
127.0.0.1        localhost
127.0.0.2        ndb1.cluster ndb1
```

```
#  ndb2 /etc/hosts:
127.0.0.1        localhost
127.0.0.2        ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server,

but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

> **Caution**
>
> You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

Host computer type.   Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

Network hardware.   Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) MySQL Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

> **Important**
>
> MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run a MySQL Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

Sample data.   We use the `world` database which is available for download from the MySQL Web site (see http://dev.mysql.com/doc/index-other.html). We assume that each machine has sufficient memory for running the operating system, required MySQL Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, *Installing and Upgrading MySQL*. For information about installation of MySQL Cluster on Linux and other Unix-like operating systems, see Section 17.2.1, "Installing MySQL Cluster on Linux". For information about installation of MySQL Cluster on Windows operating systems, see Section 17.2.2, "Installing MySQL Cluster on Windows".

For general information about MySQL Cluster hardware, software, and networking requirements, see Section 17.1.3, "MySQL Cluster Hardware, Software, and Networking Requirements".

17.2.1 Installing MySQL Cluster on Linux

This section covers installation of MySQL Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms.

Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also supported for production use on Windows operating systems; for installation and setup instructions specific to Windows, see Section 17.2.2, "Installing MySQL Cluster on Windows".

Each MySQL Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the

management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd`; in MySQL Cluster NDB 7.0 and later, you can use `ndbmtd` instead. It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of MySQL Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the MySQL Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 17.2.3, "Initial Configuration of MySQL Cluster".

17.2.1.1 Installing a MySQL Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the latest MySQL Cluster NDB 6.3, MySQL Cluster NDB 7.0, or MySQL Cluster NDB 7.1 binary archive (`mysql-cluster-gpl-6.3.55-linux-i686-glibc23.tar.gz`, `mysql-cluster-gpl-7.0.42-linux-i686-glibc23.tar.gz`, or `mysql-cluster-gpl-7.1.37-linux-i686-glibc23.tar.gz`, respectively) from the MySQL Cluster downloads area. We assume that you have placed this file in each machine's `/var/tmp` directory. (If you do require a custom binary, see Section 2.11.3, "Installing MySQL Using a Development Source Tree".)

> **Note**
>
> After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 17.2.3, "Initial Configuration of MySQL Cluster").

SQL nodes.   On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

   ```
   shell> groupadd mysql
   shell> useradd -g mysql -s /bin/false mysql
   ```

   The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory. Note that the actual file and directory names vary according to the MySQL Cluster version number.

   ```
   shell> cd /var/tmp
   shell> tar -C /usr/local -xzvf mysql-cluster-gpl-7.1.37-linux-i686-glibc23.tar.gz
   shell> ln -s /usr/local/mysql-cluster-gpl-7.1.37-linux-i686-glibc23 /usr/local/mysql
   ```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

Data nodes. Installation of the data nodes does not require the `mysqld` binary. Only the MySQL Cluster data node executable `ndbd` (single-threaded) or `ndbmtd` (multi-threaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.1.77-ndb-7.1.37-linux-i686-glibc23.tar.gz
shell> cd mysql-5.1.77-ndb-7.1.37-linux-i686-glibc23
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmtd /usr/local/bin/ndbmtd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run a MySQL Cluster data node, we have shown you how to install both `ndbd` and `ndbmtd` in the preceding instructions. We recommend that you do

this when installing or upgrading MySQL Cluster, even if you plan to use only one of them, since this will save time and trouble in the event that you later decide to change from one to the other.

> **Note**
>
> The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See Section 17.2.3, "Initial Configuration of MySQL Cluster".)

Management nodes. Installation of the management node does not require the `mysqld` binary. Only the MySQL Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

   ```
   shell> cd /var/tmp
   shell> tar -zxvf mysql-5.1.77-ndb-7.1.37-linux-i686-glibc23.tar.gz
   shell> cd mysql-5.1.77-ndb-7.1.37-linux-i686-glibc23
   shell> cp bin/ndb_mgm* /usr/local/bin
   ```

   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

   ```
   shell> cd /usr/local/bin
   shell> chmod +x ndb_mgm*
   ```

In Section 17.2.3, "Initial Configuration of MySQL Cluster", we create configuration files for all of the nodes in our example MySQL Cluster.

17.2.1.2 Installing MySQL Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of MySQL Cluster node using RPM packages supplied by Oracle.

RPMs are available for both 32-bit and 64-bit Linux platforms. For a MySQL Cluster, three RPMs are required:

- The **Server** RPM (for example, `MySQL-Cluster-gpl-server-6.3.55-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-server-7.0.42-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-server-7.1.37-0.sles10.i586.rpm`), which supplies the core files needed to run a MySQL Server with `NDBCLUSTER` storage engine support (that is, as a MySQL Cluster SQL node).

  If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the **Client** RPM (for example, `MySQL-Cluster-gpl-client-6.3.55-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-client-7.0.42-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-client-7.1.37-0.sles10.i586.rpm`).

- The **Cluster storage engine** RPM (for example, `MySQL-Cluster-gpl-storage-6.3.55-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-storage-7.0.42-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-storage-7.1.37-0.sles10.i586.rpm`), which supplies the MySQL Cluster data node binary (`ndbd`).

- The **Cluster storage engine management RPM** (for example, `MySQL-Cluster-gpl-management-6.3.55-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-management-7.0.42-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-management-7.1.37-0.sles10.i586.rpm`) which provides the MySQL Cluster management server binary (`ndb_mgmd`).

In addition, you should also obtain the **NDB Cluster - Storage engine basic tools** RPM (for example, `MySQL-Cluster-gpl-tools-6.3.55-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-tools-7.0.42-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-tools-7.1.37-0.sles10.i586.rpm`), which supplies several useful applications for working with a MySQL Cluster. The most important of these is the MySQL Cluster management client (`ndb_mgm`). The **NDB Cluster - Storage engine extra tools** RPM (for example, `MySQL-Cluster-gpl-extra-6.3.55-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-extra-7.0.42-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-extra-7.1.37-0.sles10.i586.rpm`) contains some additional testing and monitoring programs, but is not required to install a MySQL Cluster. (For more information about these additional programs, see Section 17.4, "MySQL Cluster Programs".)

The MySQL Cluster version number in the RPM file names (shown here as `6.3.55`, `7.0.42`, or `7.1.37`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The `glibc` version number (if present), and architecture designation (shown here as `i586`) should be appropriate to the machine on which the RPM is to be installed.

Data nodes.   On a computer that is to host a cluster data node it is necessary to install only the **NDB Cluster - Storage engine** RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-gpl-storage-7.1.37-0.sles10.i586.rpm
```

The previous command installs the MySQL Cluster data node binary (`ndbd`) in the `/usr/sbin` directory.

SQL nodes.   On each machine to be used for hosting a cluster SQL node, install the **Server** RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-gpl-server-7.1.37-0.sles10.i586.rpm
```

This installs the MySQL server binary (`mysqld`) in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts in `/usr/share/mysql` and `/usr/bin`, respectively. The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

> **Note**
>
> To administer the SQL node (MySQL server), you should also install the **Client** RPM, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-gpl-client-7.1.37-0.sles10.i586.rpm
```

This installs the `mysql` client program.

Management nodes.   To install the MySQL Cluster management server, it is necessary only to use the **NDB Cluster - Storage engine management** RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the **Storage engine management** RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-Cluster-gpl-management-7.1.37-0.sles10.i586.rpm
```

This installs the management server binary (`ndb_mgmd`) to the `/usr/sbin` directory.

You should also install the `NDB` management client, which is supplied by the **Storage engine basic tools** RPM. Copy this RPM to the same computer as the management node, and then install it by running the following command as the system root user (again, replace the name shown for the RPM as necessary to match that of the **Storage engine basic tools** RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-Cluster-gpl-tools-7.1.37-0.sles10.i586.rpm
```

The **Storage engine basic tools** RPM installs the MySQL Cluster management client (`ndb_mgm`) to the `/usr/bin` directory.

> **Note**
>
> You can also install the **Cluster storage engine extra tools** RPM, if you wish, as shown here:
>
> ```
> shell> rpm -Uhv MySQL-Cluster-gpl-extra-7.1.37-0.sles10.i586.rpm
> ```
>
> You may find the extra tools useful; however the **Cluster storage engine extra tools** RPM is *not* required to install a working MySQL Cluster.

See Section 2.5.1, "Installing MySQL on Linux Using RPM Packages", for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster as discussed in Section 17.2.3, "Initial Configuration of MySQL Cluster".

17.2.1.3 Building MySQL Cluster from Source on Linux

This section provides information about compiling MySQL Cluster on Linux and other Unix-like platforms. Building MySQL Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.11, "Installing MySQL from Source". Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also supported on Windows platforms, and can be built on Windows from source. For information about compiling MySQL Cluster on Windows platforms, see Section 17.2.2.2, "Compiling and Installing MySQL Cluster from Source on Windows".

Building MySQL Cluster requires using the MySQL Cluster sources. These are available from the MySQL Cluster downloads page at http://dev.mysql.com/downloads/cluster/. The archived source file should have a name similar to `mysql-cluster-gpl-6.3.55.tar.gz`, `mysql-cluster-gpl-7.0.42.tar.gz`,

or `mysql-cluster-gpl-7.1.37.tar.gz`. You can also obtain MySQL development sources from launchpad.net. Attempting to build MySQL Cluster from standard MySQL 5.1 sources is not supported.

In addition to any other `configure` options you wish to use, be sure to include `--with-plugins=ndbcluster`, `--with-plugins=max`, or , or `--with-plugins=max-no-innodb`. Either of these options causes the binaries for the management nodes, data nodes, and other MySQL Cluster programs to be built; it also causes `mysqld` to be compiled with `NDB` storage engine support.

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location. However, the layout can differ. These differences are covered in the next few paragraphs.

Prior to MySQL Cluster NDB 7.1.9, MySQL Cluster was not compatible with the `InnoDB` Plugin; in earlier MySQL Cluster releases, only the version of `InnoDB` supplied with the MySQL Server could be used. Beginning with MySQL Cluster NDB 7.1.9, you can build MySQL Cluster with `InnoDB` storage engine or plugin support using the appropriate `--with-plugins` option for `configure`.

Management nodes.   When building from source and running the default `make install`, the management server binary (`ndb_mgmd`) is placed in `/usr/local/mysql/libexec`, while the management client binary (`ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

Data nodes.   The only executable required on a data node host is `ndbd` (`mysqld`, for example, does not have to be present on the host machine). By default when doing a source build, this file is placed in the directory `/usr/local/mysql/libexec`. For installing on multiple data node hosts, only `ndbd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) `ndbd` need not be in any particular location on the host's file system, as long as the location is known.

When compiling MySQL Cluster NDB 7.0 or later from source, no special options are required for building multi-threaded data node binaries. On Unix platforms, configuring the build with any of the options `--with-plugins=ndbcluster`, `--with-plugins=max`, or `--with-plugins=max-no-innodb` causes `ndbmtd` to be built automatically; `make install` places the `ndbmtd` binary in the `libexec` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

SQL nodes.   If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Section 2.11, "Installing MySQL from Source" to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.11, "Installing MySQL from Source" on each machine. If you configure the build with a nondefault `--prefix`, you need to adjust the directory accordingly.

In Section 17.2.3, "Initial Configuration of MySQL Cluster", we create configuration files for all of the nodes in our example MySQL Cluster.

17.2.2 Installing MySQL Cluster on Windows

Experimental support for MySQL Cluster on Microsoft Windows operating systems was introduced in MySQL Cluster NDB 7.0. Beginning with MySQL Cluster NDB 7.1.3, production support is provided for MySQL Cluster on Windows, and MySQL Cluster binaries for Windows can be obtained from http://

dev.mysql.com/downloads/cluster/. For information about installing MySQL Cluster on Windows from a binary release provided by Oracle, see Section 17.2.2.1, "Installing MySQL Cluster on Windows from a Binary Release".

It is also possible to compile and install MySQL Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 17.2.2.2, "Compiling and Installing MySQL Cluster from Source on Windows".

17.2.2.1 Installing MySQL Cluster on Windows from a Binary Release

This section describes a basic installation of MySQL Cluster on Windows using a binary `no-install` MySQL Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 17.2, "MySQL Cluster Installation and Upgrades"), as shown in the following table:

Node	IP Address
Management (MGMD) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

As on other platforms, the MySQL Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmtd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmtd.exe`, the multi-threaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of MySQL Cluster node.

`ndbmtd.exe` was not included in MySQL Cluster NDB 7.1.3 binary releases for Windows, due to a problem with `make_win_bin_dist`. This issue was corrected in MySQL Cluster NDB 7.1.5.

> **Note**
>
> As with other Windows programs, MySQL Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up a MySQL Cluster using Oracles's `no-install` binaries, the first step in the installation process is to download the latest MySQL Cluster Windows binary archive from http://dev.mysql.com/downloads/cluster/. This archive has a filename of the form `mysql-cluster-gpl-noinstall-ver-winarch.zip`, where `ver` is the NDB storage engine version (such as `7.1.3`), and `arch` is the architecture (`32` for 32-bit binaries, and `64` for 64-bit binaries). For example, the MySQL Cluster NDB 7.1.3 `no-install` archive for 32-bit Windows systems is named `mysql-cluster-gpl-noinstall-7.1.3-win32.zip`.

You can run 32-bit MySQL Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit MySQL Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit MySQL Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

SQL node. We assume that you have placed a copy of the `no-install` archive in the directory `C:\Documents and Settings\`*`username`*`\My Documents\Downloads` on the computer having the IP address 192.168.0.20, where *`username`* is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run MySQL Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-noinstall-`*`ver`*`-`*`winarch`*. Rename this directory to `C:\mysql`.

It is possible to install the MySQL Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 5.1`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 5.1\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.6, "Installing MySQL on Microsoft Windows Using a noinstall Zip Archive".

For a MySQL Server with MySQL Cluster support to run as part of a MySQL Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                        # run NDB storage engine
ndb-connectstring=192.168.0.10  # location of management server
```

You can add other options used by this MySQL Server if desired (see Section 2.3.6.2, "Creating an Option File"), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

Data nodes. A MySQL Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndbmtd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmtd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 192.168.0.30 and 192.168.0.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of a MySQL Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
```

```
ndb-connectstring=192.168.0.10   # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:mysql\my.ini` on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the MySQL Cluster, which leaves only the management node to be installed and configured.

Management node.   The only executable program required on a computer used for hosting a MySQL Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the MySQL Cluster once it has been started, you should also install the MySQL Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 192.168.0.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the MySQL Cluster global configuration file (see item 2).

    To create this file, start a new text file in Notepad or another text editor, and enter the following information:

    ```
    [mysql_cluster]
    # Options for management node process
    config-file=C:/mysql/bin/config.ini
    ```

    Save this file as the text file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the MySQL Cluster as a whole. At a minimum, this file must contain a section for each node in the MySQL Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:

    *   The IP address or hostname of any SQL nodes

    *   The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)

    *   The number of replicas, using the `NoOfReplicas` configuration parameter (see Section 17.1.2, "MySQL Cluster Nodes, Node Groups, Replicas, and Partitions")

    *   The directory where each data node stores it data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

    Create a new text file using a text editor such as Notepad, and input the following information:

    ```
    [ndbd default]
    # Options affecting ndbd processes on all data nodes:
    NoOfReplicas=2                       # Number of replicas
    DataDir=C:/mysql/cluster-data        # Directory for each data node's data files
                                         # Forward slashes used in directory path,
                                         # rather than backslashes. This is correct;
                                         # see Important note in text
    DataMemory=80M     # Memory allocated to data storage
    ```

```
IndexMemory=18M    # Memory allocated to index storage
                   # For DataMemory and IndexMemory, we have used the
                   # default values. Since the "world" database takes up
                   # only about 500KB, this should be more than enough for
                   # this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=192.168.0.10              # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs  # Directory for management node log files

[ndbd]
# Options for data node "A":
                                 # (one [ndbd] section per data node)
HostName=192.168.0.30            # Hostname or IP address

[ndbd]
# Options for data node "B":
HostName=192.168.0.40            # Hostname or IP address

[mysqld]
# SQL node options:
HostName=192.168.0.20            # Hostname or IP address
```

Save this file as the text file `C:\mysql\bin\config.ini`.

Important

A single backslash character (`\`) cannot be used when specifying directory paths in program options or configuration files used by MySQL Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (`\\`), or replace the backslash with a forward slash character (`/`). For example, the following line from the `[ndb_mgmd]` section of a MySQL Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs     # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in MySQL Cluster program options and configuration files on Windows.

17.2.2.2 Compiling and Installing MySQL Cluster from Source on Windows

Oracle provides precompiled MySQL Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile MySQL Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

• To build MySQL Cluster, you must use the MySQL Cluster sources, which you can obtain from http://dev.mysql.com/downloads/cluster/.

Attempting to build MySQL Cluster from the source code for the standard MySQL Server is likely not to be successful, and is not supported by Oracle.

- You must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option in addition to any other build options you wish to use before creating the Visual Studio project files. Once you have run `configure.js` with the desired options, you can create the project files and build from them in the same manner as you do when compiling the standard MySQL Server. For more information, see Section 2.11.7, "Installing MySQL from Source on Windows".

Prior to MySQL Cluster NDB 7.1.9, MySQL Cluster was not compatible with the `InnoDB` Plugin; in earlier MySQL Cluster releases, only the version of `InnoDB` supplied with the MySQL Server could be used. Beginning with MySQL Cluster NDB 7.1.9, you can build MySQL Cluster with `InnoDB` storage engine or plugin support on Windows using `WITH_INNOBASE_STORAGE_ENGINE` with `configure.js`-

Once the build process is complete, you can create a Zip archive containing the compiled binaries by running `make_win_bin_dist`. The MySQL Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For basic information about how to accomplish these tasks, see Section 17.2.2.1, "Installing MySQL Cluster on Windows from a Binary Release".

On Windows, beginning with MySQL Cluster NDB 7.0.11, using `WITH_NDBCLUSTER_STORAGE_ENGINE` with `configure.js` causes `ndbmtd.exe` to be built automatically, and to be found in the `bin` directory of the archive created by `make_win_bin_dist`. (It was not possible to build `ndbmtd.exe` on Windows prior to MySQL Cluster NDB 7.0.11.)

17.2.2.3 Initial Startup of MySQL Cluster on Windows

Once the MySQL Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the MySQL Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-5.1.77-ndb-7.1.37
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used MySQL Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of MySQL Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See Section 17.2.2.4, "Installing MySQL Cluster Processes as Windows Services", where we show how to install and run MySQL Cluster processes as Windows services.)

The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

> **Important**
>
> A MySQL Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have

corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

For additional information about options which can be used with `ndb_mgmd`, see Section 17.4.4, "`ndb_mgmd` — The MySQL Cluster Management Server Daemon", as well as Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see Section 17.2.2.4, "Installing MySQL Cluster Processes as Windows Services".)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the MySQL Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL+C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive MySQL Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.1.77-ndb-7.1.37)
Node 3: starting (Last completed phase 3) (mysql-5.1.77-ndb-7.1.37)

Node 2: starting (Last completed phase 4) (mysql-5.1.77-ndb-7.1.37)
Node 3: starting (Last completed phase 4) (mysql-5.1.77-ndb-7.1.37)

Node 2: Started (version 7.1.37)
Node 3: Started (version 7.1.37)

ndb_mgm>
```

Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see Section 17.5.2, "Commands in the MySQL Cluster Management Client".

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the MySQL Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the MySQL Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the MySQL Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

   Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

   ```
   C:\mysql\bin> mysqld --console
   ```

   The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

   In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

   ```
   ndb_mgm> SHOW
   Connected to Management Server at: localhost:1186
   Cluster Configuration
   ---------------------
   [ndbd(NDB)]     2 node(s)
   id=2    @192.168.0.30  (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0, *)
   id=3    @192.168.0.40  (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0)

   [ndb_mgmd(MGM)] 1 node(s)
   id=1    @192.168.0.10  (Version: 5.1.77-ndb-7.1.37)

   [mysqld(API)]   1 node(s)
   id=4    @192.168.0.20  (Version: 5.1.77-ndb-7.1.37)
   ```

   You can also verify that the SQL node is connected to the MySQL Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using MySQL Cluster's `NDBCLUSTER` storage engine. See Section 17.2.5, "MySQL Cluster Example with Tables and Data", for more information and examples.

Beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, you can install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtd.exe` as Windows services. For information on how to do this, see Section 17.2.2.4, "Installing MySQL Cluster Processes as Windows Services").

17.2.2.4 Installing MySQL Cluster Processes as Windows Services

Once you are satisfied that MySQL Cluster is running as desired, you can—beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5—install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `NET START` or `NET STOP` command, or using the Windows graphical `Services` utility.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'MySQL Cluster Management Server'
  as '"C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"'
Service successfully installed.
```

Important

When installing a MySQL Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> NET START ndb_mgmd
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP ndb_mgmd
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

You can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP  'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

However, it is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'MySQL Cluster Management Server'
      as '"C:\mysql\bin\ndb_mgmd.exe" "--service=mgmd1"'
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> NET START mgmd1
```

```
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP mgmd1
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

To remove the management node service, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'MySQL Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, you can remove the service by passing this name as the value of the `--remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.
```

Installation of a MySQL Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'MySQL Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.
```

Now you can start or stop the data node using either the default service name or the descriptive name with `net start` or `net stop`, as shown in the following example:

```
C:\> NET START ndbd
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP ndbd
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.

C:\> NET START 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

To remove the data node service, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'MySQL Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as '"C:\mysql\bin\ndbd.exe" "--service=dnode1"'
Service successfully installed.

C:\> NET START dnode1
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP dnode1
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, by passing it as the value of the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `NET START`, `NET STOP`, and `mysqld --remove`. For additional information, see Section 2.3.6.7, "Starting MySQL Server as a Microsoft Windows Service".

17.2.3 Initial Configuration of MySQL Cluster

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

  For more information on connection strings, see Section 17.3.3.3, "MySQL Cluster Connection Strings".

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the data nodes and SQL nodes.   The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster                      # run NDB storage engine

[mysql_cluster]
```

```
# Options for MySQL Cluster processes:
ndb-connectstring=192.168.0.10  # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node "A", data node "B", and the SQL node.

> **Important**
>
> Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

Configuring the management node.   The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2     # Number of replicas
DataMemory=80M     # How much memory to allocate for data storage
IndexMemory=18M    # How much memory to allocate for index storage
                   # For DataMemory and IndexMemory, we have used the
                   # default values. Since the "world" database takes up
                   # only about 500KB, this should be more than enough for
                   # this example Cluster setup.

[tcp default]
# TCP/IP options:
portnumber=2202    # This the default; however, you can use any
                   # port that is free for all the hosts in the cluster
                   # Note: It is recommended that you do not specify the port
                   # number at all and simply allow the default value to be used
                   # instead

[ndb_mgmd]
# Management process options:
hostname=192.168.0.10           # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster  # Directory for MGM node log files

[ndbd]
# Options for data node "A":
                                # (one [ndbd] section per data node)
hostname=192.168.0.30           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[ndbd]
# Options for data node "B":
hostname=192.168.0.40           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[mysqld]
# SQL node options:
hostname=192.168.0.20           # Hostname or IP address
                                # (additional mysqld connections can be
```

```
                              # specified for this node for various
                              # purposes such as running ndb_restore)
```

> **Note**
>
> The `world` database can be downloaded from http://dev.mysql.com/doc/index-other.html.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 17.2.4, "Initial Startup of MySQL Cluster".

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see Section 17.3.3, "MySQL Cluster Configuration Files", and Section 17.3, "Configuration of MySQL Cluster NDB 6.1-7.1". For configuration of MySQL Cluster as relates to making backups, see Section 17.5.3.3, "Configuration for MySQL Cluster Backups".

> **Note**
>
> The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

17.2.4 Initial Startup of MySQL Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

   ```
   shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
   ```

   ndb_mgmd must be told where to find its configuration file, using the `-f` or `--config-file` option. (See Section 17.4.4, "ndb_mgmd — The MySQL Cluster Management Server Daemon", for details.)

   For additional options which can be used with ndb_mgmd, see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

2. On each of the data node hosts, run this command to start the ndbd process:

   ```
   shell> ndbd
   ```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the ndb_mgm management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
```

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=2    @192.168.0.30  (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=3    @192.168.0.40  (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @192.168.0.10  (Version: 5.1.77-ndb-7.1.37)

[mysqld(API)]   1 node(s)
id=4    @192.168.0.20  (Version: 5.1.77-ndb-7.1.37)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as a MySQL Cluster API node.

> **Note**
>
> The IP address shown for a given MySQL Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See Section 17.2.5, "MySQL Cluster Example with Tables and Data", for a brief discussion.

17.2.5 MySQL Cluster Example with Tables and Data

> **Note**
>
> The information in this section applies to MySQL Cluster running on both Unix and Windows platforms.

Working with database tables and data in MySQL Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

  ```
  CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
  ```

  Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

  ```
  ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
  ```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support MySQL Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=`*engine_name* or `ENGINE=`*engine_name* with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running SELECT queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the root password at the Enter password: prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.77-ndb-7.1.37

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's root account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong root password. For more information, see Section 2.12.4, "Securing the Initial MySQL Accounts".

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the root account) effects only applications that access the SQL node, not interaction between nodes. See Section 17.5.11.2, "MySQL Cluster and MySQL Privileges", for more information.

If you did not modify the ENGINE clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE city ENGINE=NDBCLUSTER;
mysql> ALTER TABLE country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE countrylanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a SELECT query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM city ORDER BY Population DESC LIMIT 5;
+-----------+------------+
| Name      | Population |
+-----------+------------+
| Bombay    |   10500000 |
| Seoul     |    9981619 |
| São Paulo |    9968485 |
| Shanghai  |    9696300 |
| Jakarta   |    9604900 |
+-----------+------------+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief

example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
  "http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
          content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing ="1">
  <tbody>
  <tr>
    <th width="10%">City</th>
    <th>Population</th>
  </tr>
<?
    # then display the results...
    while($row = $result->fetch_object())
      printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
              $row->Name, $row->Population);
?>
  </tbody
</table>
<?
  # ...and verify the number of rows that were retrieved
    printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

17.2.6 Safe Shutdown and Restart of MySQL Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs", for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `NET STOP MYSQL`.

To restart the cluster on Unix platforms, run these commands:

* On the management host (`192.168.0.10` in our example setup):

  ```
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

* On each of the data node hosts (`192.168.0.30` and `192.168.0.40`):

  ```
  shell> ndbd
  ```

* Use the `ndb_mgm` client to verify that both data nodes have started successfully.

* On the SQL host (`192.168.0.20`):

  ```
  shell> mysqld_safe &
  ```

On Windows platforms, assuming that you have installed all MySQL Cluster processes as Windows services using the default service names (see Section 17.2.2.4, "Installing MySQL Cluster Processes as Windows Services"), you can restart the cluster as follows:

* On the management host (`192.168.0.10` in our example setup), execute the following command:

  ```
  C:\> NET START ndb_mgmd
  ```

* On each of the data node hosts (`192.168.0.30` and `192.168.0.40`), execute the following command:

  ```
  C:\> NET START ndbd
  ```

* On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see Section 17.2.2.3, "Initial Startup of MySQL Cluster on Windows").

* On the SQL node host (`192.168.0.20`), execute the following command:

  ```
  C:\> NET START mysql
  ```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster".

17.2.7 Upgrading and Downgrading MySQL Cluster

This section provides information about MySQL Cluster software and table file compatibility between MySQL 5.1.23 and earlier, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See Section 17.3, "Configuration of MySQL Cluster NDB 6.1-7.1".

For information regarding the rolling restart procedure used to perform an online upgrade, see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster".

> **Important**
>
> Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software.* See Section 2.13.1, "Upgrading MySQL".

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1, see Section 17.2.7.1, "Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x".

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 6.1, MySQL Cluster NDB 6.2, and MySQL Cluster NDB 6.3, see Section 17.2.7.2, "Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x".

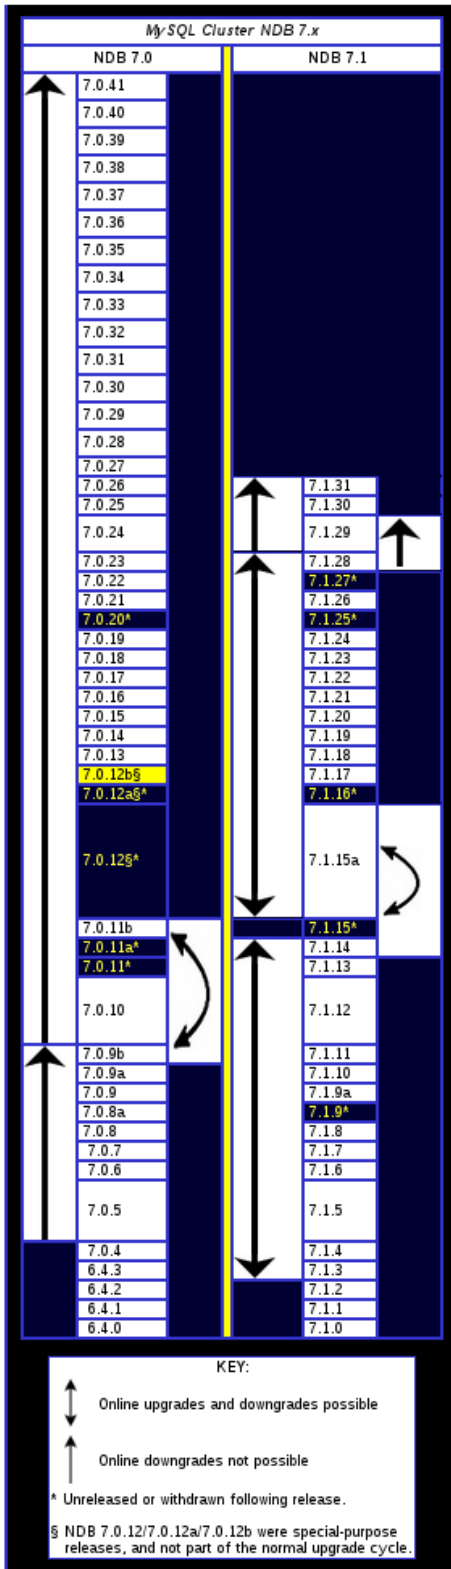
For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 7.2, see Upgrading and Downgrading MySQL Cluster NDB 7.2.

For information about upgrades and downgrades to, from, and between different editions of MySQL Cluster as found in standard MySQL 5.1.23 and earlier releases, see Section 17.2.7.3, "Upgrade and downgrade compatibility: MySQL 5.1".

> **Important**
>
> Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software.* See Section 2.13.1, "Upgrading MySQL".

17.2.7.1 Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL Cluster NDB 7.0 and 7.1. Additional notes about upgrades and downgrades to, from, or within the MySQL Cluster NDB 7.x release series can be found immediately following the table.

Figure 17.5 MySQL Cluster Upgrade and Downgrade compatibility, MySQL Cluster NDB 7.x


Notes: MySQL Cluster NDB 7.x

Versions supported.   Online upgrades from any MySQL Cluster NDB 7.0 release up to and including MySQL Cluster NDB 7.0.4 (as well as all early releases numbered NDB 6.4.x) to MySQL Cluster NDB 7.0.5 or later are not possible. Upgrades to MySQL Cluster NDB 7.0.6 or later from MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release, or from MySQL Cluster NDB 7.0.5 or later, are supported. (Bug #44294)

Upgrading ndbd to ndbmtd.   When upgrading online from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 (or later) release, you should not try to upgrade the data nodes from `ndbd` to `ndbmtd` at the same time. Instead, perform the upgrade using the new `ndbd` executable (from the MySQL Cluster NDB 7.0 or later distribution to which you are upgrading) to replace the one in use on the data nodes. Once the version upgrade is complete, you can perform a second (online) upgrade to replace the data node executables with `ndbmtd` from the newer distribution. Changing the data node binary type should not be an issue when upgrading from MySQL Cluster NDB 7.0 or later version.

Changes in default values.   In MySQL Cluster NDB 7.0.4, the default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering changed (see http:// dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-32-ndb-7-0-4.html, for a list of the parameters whose defaults changed). For this reason, you may encounter issues if you try to use a configuration that does not explicitly define each of these buffers (because it was developed for a previous version of MySQL Cluster), `SendBufferMemory` and `ReceiveBufferMemory` in particular.

Other known issues include the following:

- Prior to MySQL Cluster NDB 7.0.7, DML statements failed if executed while performing an online upgrade from a MySQL Cluster NDB 6.3 release. (Bug #45917)

- Following an upgrade from any MySQL Cluster NDB 6.3.x release to MySQL Cluster NDB 7.0.6, DDL and backup operations failed. This issue was resolved in MySQL Cluster NDB 7.0.7. (Bug #46494, Bug #46563)

- In some cases, there could be problems with online upgrades from MySQL Cluster NDB 6.3 releases to MySQL Cluster NDB 7.0 releases due to a previous change in the signalling format used between nodes. This issue was corrected in MySQL Cluster NDB 7.0.9.

- Once an `NDB` table had an `ALTER ONLINE TABLE` operation performed on it using a MySQL Cluster NDB 6.3.x release, it could not be upgraded online to MySQL Cluster NDB 7.0. This issue was resolved in MySQL Cluster NDB 7.0.8. (See Bug #47542.)

- Following an upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0, if there were any tables having unique indexes prior to the upgrade, attempts to create unique indexes failed. This could also occur when performing offline `ALTER TABLE` operations on tables having indexes that were not dropped as a result of the `ALTER TABLE`. This issue was due to a change in the way that `NDB` tracked unique indexes internally, and was resolved in MySQL Cluster NDB 7.0.9. (Bug #48416)

  For upgrades to MySQL Cluster NDB 7.0 releases prior to version 7.0.9, a workaround is available: Following the upgrade, execute a *second* rolling restart of the cluster before performing any `ALTER TABLE` operations involving indexes.

- Due to an issue discovered after the release of MySQL Cluster NDB 7.0.10 (Bug #50433), it is not possible to perform an online upgrade from MySQL Cluster NDB 7.0.9b and earlier MySQL Cluster NDB 7.0 releases to MySQL Cluster NDB 7.0.10. Instead, you should upgrade your MySQL Cluster NDB 7.0 installation directly to MySQL Cluster NDB 7.0.11 or later.

This issue did not appear to affect MySQL Cluster NDB 6.3, and it should be possible to upgrade online from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.10 without any problems other than those noted previously.

- It was not possible to perform an online upgrade from a MySQL Cluster NDB 6.3 or 7.0 release to MySQL Cluster NDB 7.1.0 or 7.1.1. This issue was fixed in MySQL Cluster NDB 7.1.2 (see Bug #51429).

- Following an upgrade to MySQL Cluster NDB 7.0.15 or later (MySQL Cluster NDB 7.0), or to MySQL Cluster NDB 7.1.4 or later (MySQL Cluster NDB 7.1), a table created in a previous version of MySQL Cluster does *not* automatically support `NDB`-native default values. Such a table continues to use default values supplied by the MySQL server until it is upgraded by performing an offline `ALTER TABLE` on it.

  When upgrading to a MySQL Cluster release that supports native default values from a MySQL Cluster release that does not, you should not attempt to create any new tables until all data nodes are using the new `ndbd` or `ndbmtd` binaries. This is because the older binaries do not provide support for native default values.

  > **Important**
  >
  > Tables created with native default value support cannot be used with versions of MySQL Cluster that do not support native default values.

- NDB API changes in MySQL Cluster NDB 7.1.16 and MySQL Cluster NDB 7.0.27 are not backward compatible. Due to these changes the version of the included NDB client library was increased from 4.0.0 to 5.0.0; NDB API applications must be recompiled as part of any upgrade to these or later MySQL Cluster releases.

  In addition, NDB API programs should be updated as part of such an upgrade, in order to take into account changes in the default behavior and values for the `Ndb_cluster_connection::connect()` method.

- Due to issues discovered shortly after release, MySQL Cluster NDB 7.0.20 was withdrawn and replaced with MySQL Cluster NDB 7.0.20a. Users of MySQL Cluster NDB 7.0.19 and previous MySQL Cluster NDB 7.0 releases should upgrade to MySQL Cluster NDB 7.0.20a, or to a later MySQL Cluster NDB 7.0 release. See http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-51-ndb-7-0-20a.html, for more information.

  Due to issues discovered following release, MySQL Cluster NDB 7.1.15 was withdrawn and replaced with MySQL Cluster NDB 7.1.15a. Users of MySQL Cluster NDB 7.1.14 and previous MySQL Cluster NDB 7.1 releases should upgrade to MySQL Cluster NDB 7.1.15a, or to a later MySQL Cluster NDB 7.1 release. See http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-56-ndb-7-1-15a.html, for more information.

  Due to issues discovered shortly after release, MySQL Cluster NDB 7.1.9 was withdrawn and replaced with MySQL Cluster NDB 7.1.9a. Users of MySQL Cluster NDB 7.1.8 and previous MySQL Cluster NDB 7.1 releases should upgrade to MySQL Cluster NDB 7.1.14 (the last release directly upgrade-compatible with MySQL Cluster 7.1.18 and earlier) before upgrading to MySQL Cluster 7.1.15a or later. See http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-51-ndb-7-1-9a.html, for more information.

- When performing an online upgrade or downgrade between MySQL Cluster NDB 7.1.8 or earlier and a later release up to and including MySQL Cluster NDB 7.1.14, you must upgrade or downgrade the data nodes before upgrading or downgrading any SQL nodes; otherwise `mysql_upgrade` fails on the SQL nodes due to differences between `ndbinfo` tables used in the "old" and "new" versions of the MySQL Cluster software. You should also upgrade or downgrade the data nodes prior to the SQL nodes when

performing an online upgrade or downgrade between MySQL Cluster NDB 7.1 releases where either of the versions involved is MySQL Cluster NDB 7.1.14 or earlier, and where one or more `ndbinfo` tables has more, fewer, or differing columns between the two versions.

This issue is resolved in MySQL Cluster NDB 7.1.15. (Bug #11885602)

- It was not possible to downgrade online to MySQL Cluster NDB 7.1 from some later versions of MySQL Cluster due to a change in the size used for table hash maps by `NDB`. (Bug #14645319) This issue was resolved in MySQL Cluster NDB 7.1.26, where the size is made configurable using the `DefaultHashMapSize` parameter. (Bug #14800539) See the description of this parameter for more information.

17.2.7.2 Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL Cluster NDB 6.1, 6.2, and 6.3. Additional notes about upgrades and downgrades to, from, or within the MySQL Cluster NDB 6.x release series can be found immediately following the table.

Downgrade compatibility, MySQL Cluster NDB 6.x

6.1.1	6.2.1	6.3.1
6.1.0	6.2.0	6.3.0

KEY:

↕ Online upgrades and downgrades possible

↑ Online downgrades not possible

* Unreleased or withdrawn following release.

† The NDB 6.1 and 6.2 series are no longer in production.

§ NDB 6.3.30 was a special-purpose release, and not part of the normal upgrade cycle.

Notes: MySQL Cluster NDB 6.1

Availability of older releases.   MySQL Cluster NDB 6.1 is no longer in production; information about this series of releases is of historical interest only. MySQL Cluster NDB 6.2 is still available, but is no longer supported in new deployments. If you are still using a MySQL Cluster NDB 6.1 or MySQL Cluster NDB 6.2 release, you should upgrade to the most recent MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1 release as soon as possible.

- It is not possible to upgrade from MySQL Cluster NDB 6.1.2 (or an older 6.1 release) directly to 6.1.4 or a newer NDB 6.1 release, or to downgrade from 6.1.4 (or a newer 6.1 release) directly to 6.1.2 or an older NDB 6.1 release; in either case, you must upgrade or downgrade to MySQL Cluster NDB 6.1.3 first.

- It is not possible to perform an online downgrade from MySQL Cluster NDB 6.1.8 (or a newer 6.1 release) to MySQL Cluster NDB 6.1.7 (or an older 6.1 release).

- MySQL Cluster NDB 6.1.6 and 6.1.18 were not released.

- It is not possible to perform an online upgrade or downgrade between MySQL Cluster NDB 6.2 and any previous release series (including mainline MySQL 5.1 and MySQL Cluster NDB 6.1); it is necessary to perform a dump and reload. However, it should be possible to perform online upgrades or downgrades between any MySQL Cluster NDB 6.2 release and any MySQL Cluster NDB 6.3 release up to and including 6.3.7.

Notes: MySQL Cluster NDB 6.2 and MySQL Cluster NDB 6.3

Internal column specification changes.   The internal specifications for columns in `NDB` tables changed in MySQL Cluster NDB 6.1.17 and 6.2.1 to enable compatibility with later MySQL Cluster releases implementing online adding and dropping of columns (MySQL 5.1.17 through MySQL 5.1.23; MySQL Cluster NDB 6.2.3 and later; MySQL Cluster NDB 6.3.2 and later). This change is not backward-compatible with earlier MySQL Server or MySQL Cluster releases.

To make tables created in earlier versions compatible with online adding and dropping of columns in later versions, it is necessary to force MySQL Cluster to convert the tables to the new format by following this procedure following an upgrade:

1. Upgrade the MySQL Cluster software on all data, management, and SQL nodes

2. Back up all `NDB` tables

3. Shut down the cluster (all data, management, and SQL nodes)

4. Restart the cluster, starting all data nodes with the `--initial` option (to clear and rebuild the data node file systems)

5. Restore the tables from backup

To minimize possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after to upgrading between the versions indicated. The procedure is *not* necessary for `NDBCLUSTER` tables created in any of the following versions:

- MySQL Cluster NDB 6.1.8 or a later MySQL Cluster NDB 6.1 release

- MySQL Cluster 6.2.1 or a later MySQL Cluster NDB 6.2 release

- Any MySQL Cluster NDB 6.3 release (or later MySQL Cluster release series)

Tables created in the versions listed previously (or later versions, as indicated) are already compatible with adding and dropping of columns online (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).

Additional issues encountered when upgrading or downgrading to or from MySQL Cluster NDB 6.2 and MySQL Cluster NDB 6.3 releases are listed here:

- It was not possible to perform an online upgrade between any MySQL Cluster NDB 6.2 release and MySQL Cluster NDB 6.3.8 and later MySQL Cluster 6.3 releases. This issue was fixed in MySQL Cluster NDB 6.3.21. (Bug #41435)

- Online downgrades between MySQL Cluster NDB 6.2.5 and earlier releases are not supported.

- Online downgrades between MySQL Cluster NDB 6.3.8 and earlier releases are not supported.

17.2.7.3 Upgrade and downgrade compatibility: MySQL 5.1

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL 5.1 prior to MySQL 5.1.24. Additional notes about upgrades and downgrades to, from, or within the MySQL 5.1 release series can be found immediately following the table.

Figure 17.7 MySQL Cluster Upgrade and Downgrade compatibility, MySQL Cluster 5.1
Notes: MySQL 5.1

- MySQL 5.1.3 was the first public release in this series.

- Direct upgrades or downgrades between MySQL Cluster 5.0 and 5.1 are not supported; you must dump all `NDBCLUSTER` tables using `mysqldump`, install the new version of the software, and then reload the tables from the dump.

- You cannot downgrade a MySQL Cluster based on MySQL 5.1.6 or later and using Disk Data tables to MySQL 5.1.5 or earlier unless you convert all such tables to in-memory `NDB` tables first.

- MySQL 5.1.8, MySQL 5.1.10, and MySQL 5.1.13 were not released.

- Online cluster upgrades and downgrades between MySQL 5.1.11 (or an earlier version) and 5.1.12 (or a later version) are not possible due to major changes in the cluster file system. In such cases, you must perform a backup or dump, upgrade (or downgrade) the software, start each data node with `--`

`initial`, and then restore from the backup or dump. You can use native `NDB` backup and restore, or `mysqldump` and `LOAD DATA INFILE` for this purpose.

- Online downgrades from MySQL 5.1.14 or later to versions previous to 5.1.14 are not supported due to incompatible changes in the cluster system tables.

MySQL Cluster Replication: changes in ndb_apply_status.   Online upgrades from MySQL 5.1.17 and earlier to 5.1.18 and later MySQL 5.1.x releases are not supported for clusters using replication due to incompatible changes in the `mysql.ndb_apply_status` table. (Online upgrades from MySQL 5.1 to MySQL Cluster NDB 6.2 and later are not supported, as discussed elsewhere in this section.) However, it should not be necessary to shut down the cluster entirely, if you follow this modified rolling restart procedure:

1. Stop the management server, update the management server software, then start the management server again. For multiple management servers, repeat this step for each management server in turn.

2. For each data node in turn: Stop the data node, update the data node daemon (in MySQL Cluster NDB 7.0 and later, this can be either `ndbd` or `ndbmtd`) with the new version, then restart the data node. It should not be necessary to use `--initial` when restarting any of the data nodes after updating the software.

3. Stop *all* SQL nodes. Upgrade the existing MySQL server installations to the new version on all SQL nodes, then restart them. It is not necessary to start them one at a time after upgrading the MySQL server software, but *there must be a time when none of them is running before starting any of them again using the 5.1.18 (or later)* `mysqld`. Otherwise—due to the fact that `mysql.ndb_apply_status` uses the `NDB` storage engine and is thus shared between all SQL nodes—there may be conflicts between the old and new versions of the table on different SQL nodes.

   You can find more information about the changes to `ndb_apply_status` in Section 17.6.4, "MySQL Cluster Replication Schema and Tables".

   > **Note**
   >
   > You should upgrade the MySQL Cluster software on each node using the same method by which it was originally installed. See Section 17.2, "MySQL Cluster Installation and Upgrades", for more information.

As with any other MySQL Cluster version upgrade, you should also update the MySQL Cluster management client (`ndb_mgm`) and other MySQL Cluster client programs such as `ndb_config` and `ndb_error_reporter`; however, this does not have to be done in any particular order.

Internal column specification changes.   The internal specifications for columns in `NDBCLUSTER` tables changed in MySQL 5.1.18 to enable compatibility with later MySQL Cluster releases that permit online adding and dropping of columns. *This change is not backward-compatible with earlier MySQL versions.*

To make tables created in MySQL 5.1.17 and earlier compatible with online adding and dropping of columns (available beginning with beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2—see Section 13.1.7, "ALTER TABLE Syntax", for more information), it is necessary to force MySQL 5.1.18 and later to convert the tables to the new format by following this procedure:

1. Back up all `NDBCLUSTER` tables.

2. Upgrade the MySQL Cluster software on all data, management, and SQL nodes.

3. Shut down the cluster completely (this includes all data, management, and API or SQL nodes).

4. Restart the cluster, starting all data nodes with the `--initial` option (to clear and rebuild the data node file systems).

5. Restore the `NDBCLUSTER` tables from backup.

It is not necessary to follow this procedure for `NDBCLUSTER` tables created in MySQL 5.1.18 and later; such tables are already compatible with online adding and dropping of columns (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).

To minimize possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after to upgrading from MySQL 5.1.17 or earlier to MySQL 5.1.18 or later.

Information about how this change effects users of MySQL Cluster NDB 6.x and 7.x is provided later in this section.

MySQL Cluster not supported in MySQL Server 5.1.24 and later.   MySQL Cluster is not supported in standard MySQL 5.1 releases beginning with MySQL 5.1.24. If you are using MySQL Cluster in a standard MySQL 5.1 release, you should upgrade to the most recent MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1 release.

17.3 Configuration of MySQL Cluster NDB 6.1-7.1

A MySQL server that is part of a MySQL Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the `NDB` storage engine. This engine is also referred to sometimes as `NDBCLUSTER`, although `NDB` is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf`, or with the `mysql` client. Before the `NDB` storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to MySQL Cluster, see MySQL Server Options for MySQL Cluster.

For information about installing MySQL Cluster, see Section 17.2, "MySQL Cluster Installation and Upgrades".

17.3.1 Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 SQL nodes.
```

```
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but SQL nodes are not required
# to do so.
# If you do not know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld  default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

By default, `ndbd` looks for the management server at `localhost` on port 1186.

> **Note**
>
> If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the NDB storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.73

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
*************************** 12. row ***************************
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
*************************** 13. row ***************************
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an NDB table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
       Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the SHOW command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)]     1 node(s)
id=2    @127.0.0.1  (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @127.0.0.1  (Version: 5.1.77-ndb-7.1.37)

[mysqld(API)]   3 node(s)
id=3    @127.0.0.1  (Version: 5.1.77-ndb-7.1.37)
```

```
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

17.3.2 Overview of MySQL Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of MySQL Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as a MySQL Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, `shm`, or `sci`). All tables include the data type for the parameter, option, or variable, as well as its default, mimimum, and maximum values as applicable.

Considerations when restarting nodes.   For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

> **Important**
>
> Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.
>
> However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

> **Note**
>
> `4294967039` often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFEFF`, or $2^{32} - 2^{8} - 1$.

17.3.2.1 MySQL Cluster Data Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 17.3.3.6, "Defining MySQL Cluster Data Nodes".

Beginning with MySQL Cluster NDB 6.4.0, these parameters also apply to `ndbmtd`, which is a multi-threaded version of `ndbd`. For more information, see Section 17.4.3, "`ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)".

Restart types.   Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- `N`—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster").

- `S`—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- `I`—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, "Overview of MySQL Cluster Configuration Parameters, Options, and Variables".

Table 17.1 Data Node Configuration Parameters

Parameter Name	Type or Units	Restart Type	In Version ... (and later)
	Default Value

> **Note**
>
> Prior to MySQL Cluster NDB 7.0, to add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster, starting all data node processes using the `--initial` option—that is, you must perform a system restart.
>
> Beginning in MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. For more information, see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online".

17.3.2.2 MySQL Cluster Management Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 17.3.3.5, "Defining a MySQL Cluster Management Server".

Restart types.   Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- N—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster").

- `S`—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- `I`—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, "Overview of MySQL Cluster Configuration Parameters, Options, and Variables".

wan	boolean	N	NDB 6.1.1
	false		
	true, false		

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 17.3.3.5, "Defining a MySQL Cluster Management Server", for more information.

To add new management servers to a running MySQL Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing

`config.ini` files. For more information about issues arising when using multiple management nodes, see Section 17.1.6.10, "Limitations Relating to Multiple MySQL Cluster Nodes".

17.3.2.3 MySQL Cluster SQL Node and API Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 17.3.3.7, "Defining SQL and Other API Nodes in a MySQL Cluster".

> **Note**
>
> For a discussion of MySQL server options for MySQL Cluster, see MySQL Server Options for MySQL Cluster; for information about MySQL server system variables relating to MySQL Cluster, see MySQL Cluster System Variables.

Restart types.　　Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- `N`—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster").

- `S`—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- `I`—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, "Overview of MySQL Cluster Configuration Parameters, Options, and Variables".

Table 17.4 SQL Node / API Node Configuration Parameters

Parameter Name	Type or Units	Restart Type	In Version ... (and later)
	Default Value		
	Minimum/ Maximum or Permitted Values

Parameter Name	Type or Units / Default Value / Minimum/ Maximum or Permitted Values	Restart Type	In Version ... (and later)
	1024 / 1M		
`BatchSize`	records 256 1 / 992	N	NDB 7.2.1
`ConnectionMap`	string [none] ...	N	NDB 6.1.0
`DefaultHashMapSize`	buckets 240 0 / 3840	N	NDB 7.1.27
`DefaultOperationRedoProblemAction`	enumeration ABORT ABORT, QUEUE	S	NDB 7.1.10
`EventLogBufferSize`	bytes 8192 0 / 64K	S	NDB 7.0.4
`ExecuteOnComputer`	name [none] ...	S	all 5.1-based
`ExtraSendBufferMemory`	bytes 0 0 / 4294967039 (0xFFFFFEFF)	N	NDB 7.1.28
`HeartbeatThreadPriority`	string [none] ...	S	NDB 7.1.2
`HostName`	name or IP address [none] ...	N	all 5.1-based
`Id`	unsigned [none] 1 / 255	IS	NDB 6.1.1

Parameter Name	Type or Units	Restart Type	In Version ... (and later)
	Default Value		
	Minimum/ Maximum or Permitted Values		
`MaxScanBatchSize`	bytes	N	all 5.1-based
	256K		
	32K / 16M		
`NodeId`	unsigned	IS	NDB 6.1.1
	[none]		
	1 / 255		
`TotalSendBufferMemory`	bytes	N	NDB 6.4.0
	0		
	256K / 4294967039 (0xFFFFFEFF)		
`wan`	boolean	N	NDB 6.1.1
	false		
	true, false		

Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

17.3.2.4 Other MySQL Cluster Configuration Parameters

The summary tables in this section provide information about parameters used in the `[computer]`, `[tcp]`, `[shm]`, and `[sci]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about individual parameters, see Section 17.3.3.9, "MySQL Cluster TCP/IP Connections", Section 17.3.3.11, "MySQL Cluster Shared-Memory Connections", or Section 17.3.3.12, "SCI Transport Connections in MySQL Cluster", as appropriate.

Restart types.   Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary tables as follows:

- N—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster").

- S—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- I—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, "Overview of MySQL Cluster Configuration Parameters, Options, and Variables".

17.3.2.5 MySQL Cluster mysqld Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in a MySQL Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see Section 5.1.1, "Server Option and Variable Reference".

Table 17.9 MySQL Server Options and Variables for MySQL Cluster: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
Com_show_ndb_status		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW NDB STATUS statements		
Handler_discover		
No	No	Yes
No	Both	No
DESCRIPTION: Number of times that tables have been discovered		
have_ndbcluster		
No	Yes	No
No	Global	No
DESCRIPTION: Whether mysqld supports NDB Cluster tables (set by --ndbcluster option)		
ndb-batch-size		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Size (in bytes) to use for NDB transaction batches		
ndb-blob-read-batch-bytes		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.		
ndb-blob-write-batch-bytes		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.		
ndb-cluster-connection-pool		
Yes	Yes	Yes
Yes	Global	No
DESCRIPTION: Number of connections to the cluster used by MySQL		
ndb-connectstring		
Yes	No	No
Yes		No
DESCRIPTION: Point to the management server that distributes the cluster configuration		
ndb-deferred-constraints		

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.		
ndb-distribution		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)		
ndb-log-apply-status		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.		
ndb-log-empty-epochs		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.		
ndb-log-orig		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Log originating server id and epoch in mysql.ndb_binlog_index table.		
ndb-log-transaction-id		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.		
ndb-log-update-as-write		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Toggles logging of updates on the master between updates (OFF) and writes (ON)		
ndb-mgmd-host		
Yes	No	No
Yes		No
DESCRIPTION: Set the host (and port, if desired) for connecting to management server		

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
ndb-nodeid		
Yes	No	Yes
Yes	Global	No
DESCRIPTION: MySQL Cluster node ID for this MySQL server		
ndb-transid-mysql-connection-map		
Yes	No	No
No		No
DESCRIPTION: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name.		
ndb-wait-connected		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.		
ndb-wait-setup		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete.		
Ndb_api_bytes_received_count		
No	No	Yes
No	Global	No
DESCRIPTION: Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).		
Ndb_api_bytes_received_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Amount of data (in bytes) received from the data nodes in this client session.		
Ndb_api_bytes_received_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Amount of data (in bytes) received from the data nodes by this slave.		
Ndb_api_bytes_sent_count		
No	No	Yes
No	Global	No
DESCRIPTION: Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).		
Ndb_api_bytes_sent_count_session		

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
No	No	Yes
No	Session	No
DESCRIPTION: Amount of data (in bytes) sent to the data nodes in this client session.		
Ndb_api_bytes_sent_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Amount of data (in bytes) sent to the data nodes by this slave.		
Ndb_api_event_bytes_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of bytes of events received by this MySQL Server (SQL node).		
Ndb_api_event_bytes_count_injector		
No	No	Yes
No	Global	No
DESCRIPTION: Number of bytes of events received by the NDB binary log injector thread.		
Ndb_api_event_data_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of row change events received by this MySQL Server (SQL node).		
Ndb_api_event_data_count_injector		
No	No	Yes
No	Global	No
DESCRIPTION: Number of row change events received by the NDB binary log injector thread.		
Ndb_api_event_nondata_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of events received, other than row change events, by this MySQL Server (SQL node).		
Ndb_api_event_nondata_count_injector		
No	No	Yes
No	Global	No
DESCRIPTION: Number of events received, other than row change events, by the NDB binary log injector thread.		
Ndb_api_pk_op_count		
No	No	Yes
No	Global	No

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
DESCRIPTION: Number of operations based on or using primary keys by this MySQL Server (SQL node).		
Ndb_api_pk_op_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Number of operations based on or using primary keys in this client session.		
Ndb_api_pk_op_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of operations based on or using primary keys by this slave.		
Ndb_api_pruned_scan_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of scans that have been pruned to a single partition by this MySQL Server (SQL node).		
Ndb_api_pruned_scan_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Number of scans that have been pruned to a single partition in this client session.		
Ndb_api_pruned_scan_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of scans that have been pruned to a single partition by this slave.		
Ndb_api_range_scan_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of range scans that have been started by this MySQL Server (SQL node).		
Ndb_api_range_scan_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Number of range scans that have been started in this client session.		
Ndb_api_range_scan_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of range scans that have been started by this slave.		
Ndb_api_read_row_count		

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
No	No	Yes
No	Global	No
DESCRIPTION: Total number of rows that have been read by this MySQL Server (SQL node).		
	Ndb_api_read_row_count_session	
No	No	Yes
No	Session	No
DESCRIPTION: Total number of rows that have been read in this client session.		
	Ndb_api_read_row_count_slave	
No	No	Yes
No	Global	No
DESCRIPTION: Total number of rows that have been read by this slave.		
	Ndb_api_scan_batch_count	
No	No	Yes
No	Global	No
DESCRIPTION: Number of batches of rows received by this MySQL Server (SQL node).		
	Ndb_api_scan_batch_count_session	
No	No	Yes
No	Session	No
DESCRIPTION: Number of batches of rows received in this client session.		
	Ndb_api_scan_batch_count_slave	
No	No	Yes
No	Global	No
DESCRIPTION: Number of batches of rows received by this slave.		
	Ndb_api_table_scan_count	
No	No	Yes
No	Global	No
DESCRIPTION: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).		
	Ndb_api_table_scan_count_session	
No	No	Yes
No	Session	No
DESCRIPTION: Number of table scans that have been started, including scans of internal tables, in this client session.		
	Ndb_api_table_scan_count_slave	
No	No	Yes
No	Global	No

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
DESCRIPTION: Number of table scans that have been started, including scans of internal tables, by this slave.		
Ndb_api_trans_abort_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions aborted by this MySQL Server (SQL node).		
Ndb_api_trans_abort_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Number of transactions aborted in this client session.		
Ndb_api_trans_abort_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions aborted by this slave.		
Ndb_api_trans_close_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node).		
Ndb_api_trans_close_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) in this client session.		
Ndb_api_trans_close_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this slave.		
Ndb_api_trans_commit_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions committed by this MySQL Server (SQL node).		
Ndb_api_trans_commit_count_session		
No	No	Yes
No	Session	No

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
DESCRIPTION: Number of transactions committed in this client session.		
Ndb_api_trans_commit_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions committed by this slave.		
Ndb_api_trans_local_read_row_count		
No	No	Yes
No	Global	No
DESCRIPTION: Total number of rows that have been read by this MySQL Server (SQL node).		
Ndb_api_trans_local_read_row_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Total number of rows that have been read in this client session.		
Ndb_api_trans_local_read_row_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Total number of rows that have been read by this slave.		
Ndb_api_trans_start_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions started by this MySQL Server (SQL node).		
Ndb_api_trans_start_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Number of transactions started in this client session.		
Ndb_api_trans_start_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions started by this slave.		
Ndb_api_uk_op_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of operations based on or using unique keys by this MySQL Server (SQL node).		
Ndb_api_uk_op_count_session		

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
No	No	Yes
No	Session	No
DESCRIPTION: Number of operations based on or using unique keys in this client session.		
Ndb_api_uk_op_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of operations based on or using unique keys by this slave.		
Ndb_api_wait_exec_complete_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked while waiting for execution of an operation to complete by this MySQL Server (SQL node).		
Ndb_api_wait_exec_complete_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Number of times thread has been blocked while waiting for execution of an operation to complete in this client session.		
Ndb_api_wait_exec_complete_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked while waiting for execution of an operation to complete by this slave.		
Ndb_api_wait_meta_request_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked waiting for a metadata-based signal by this MySQL Server (SQL node).		
Ndb_api_wait_meta_request_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Number of times thread has been blocked waiting for a metadata-based signal in this client session.		
Ndb_api_wait_meta_request_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked waiting for a metadata-based signal by this slave.		

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
Ndb_api_wait_nanos_count		
No	No	Yes
No	Global	No
DESCRIPTION: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this MySQL Server (SQL node).		
Ndb_api_wait_nanos_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes in this client session.		
Ndb_api_wait_nanos_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this slave.		
Ndb_api_wait_scan_result_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node).		
Ndb_api_wait_scan_result_count_session		
No	No	Yes
No	Session	No
DESCRIPTION: Number of times thread has been blocked while waiting for a scan-based signal in this client session.		
Ndb_api_wait_scan_result_count_slave		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked while waiting for a scan-based signal by this slave.		
ndb_autoincrement_prefetch_sz		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: NDB auto-increment prefetch size		
ndb_cache_check_time		
Yes	Yes	No
Yes	Global	Yes

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
DESCRIPTION: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache		
`Ndb_cluster_node_id`		
No	No	Yes
No	Both	No
DESCRIPTION: If the server is acting as a MySQL Cluster node, then the value of this variable its node ID in the cluster		
`Ndb_config_from_host`		
No	No	Yes
No	Both	No
DESCRIPTION: The host name or IP address of the Cluster management server. Formerly Ndb_connected_host		
`Ndb_config_from_port`		
No	No	Yes
No	Both	No
DESCRIPTION: The port for connecting to Cluster management server. Formerly Ndb_connected_port		
`Ndb_conflict_fn_epoch`		
No	No	Yes
No	Global	No
DESCRIPTION: Number of rows that have been found in conflict by the NDB$EPOCH() conflict detection function		
`Ndb_conflict_fn_epoch_trans`		
No	No	Yes
No	Global	No
DESCRIPTION: Number of rows that have been found in conflict by the NDB$EPOCH_TRANS() conflict detection function		
`Ndb_conflict_fn_max`		
No	No	Yes
No	Global	No
DESCRIPTION: If the server is part of a MySQL Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on "greater timestamp wins" has been applied		
`Ndb_conflict_fn_old`		
No	No	Yes
No	Global	No
DESCRIPTION: If the server is part of a MySQL Cluster involved in cluster replication, the value of this variable indicates the number of times that "same timestamp wins" conflict resolution has been applied		

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
Ndb_conflict_trans_conflict_commit_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of epoch transactions committed after requiring transactional conflict handling.		
Ndb_conflict_trans_detect_iter_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.		
Ndb_conflict_trans_reject_count		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions rejected after being found in conflict by a transactional conflict function.		
Ndb_conflict_trans_row_reject_count		
No	No	Yes
No	Global	No
DESCRIPTION: Total number of rows realigned after being found in conflict by a transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.		
ndb_deferred_constraints		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.		
ndb_distribution		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)		
ndb_eventbuffer_max_alloc		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).		
Ndb_execute_count		
No	No	Yes

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
No	Global	No
DESCRIPTION: Provides the number of round trips to the NDB kernel made by operations		
ndb_extra_logging		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Controls logging of MySQL Cluster schema, connection, and data distribution events in the MySQL error log		
ndb_force_send		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Forces sending of buffers to NDB immediately, without waiting for other threads		
ndb_index_stat_cache_entries		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Sets the granularity of the statistics by determining the number of starting and ending keys		
ndb_index_stat_enable		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Use NDB index statistics in query optimization		
ndb_index_stat_option		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces		
ndb_index_stat_update_freq		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: How often to query data nodes instead of the statistics cache		
ndb_join_pushdown		
No	Yes	No
No	Both	Yes
DESCRIPTION: Enables pushing down of joins to data nodes		
ndb_log_apply_status		
Yes	Yes	No
Yes	Global	No

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
DESCRIPTION: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID.		
ndb_log_bin		
Yes	Yes	No
No	Both	Yes
DESCRIPTION: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.		
ndb_log_binlog_index		
Yes	Yes	No
No	Global	Yes
DESCRIPTION: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.		
ndb_log_empty_epochs		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.		
ndb_log_orig		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.		
ndb_log_transaction_id		
No	Yes	No
No	Global	No
DESCRIPTION: Whether NDB transaction IDs are written into the binary log. (Read-only.)		
ndb_log_updated_only		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Log complete rows (ON) or updates only (OFF)		
Ndb_number_of_data_nodes		
No	No	Yes
No	Global	No
DESCRIPTION: If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster		
ndb_optimization_delay		
No	Yes	No

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
No	Global	Yes
DESCRIPTION: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.		
	ndb_optimized_node_selection	
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Determines how an SQL node chooses a cluster data node to use as transaction coordinator		
	Ndb_pruned_scan_count	
No	No	Yes
No	Global	No
DESCRIPTION: Number of scans executed by NDB since the cluster was last started where partition pruning could be used		
	Ndb_pushed_queries_defined	
No	No	Yes
No	Global	No
DESCRIPTION: Number of joins that API nodes have attempted to push down to the data nodes		
	Ndb_pushed_queries_dropped	
No	No	Yes
No	Global	No
DESCRIPTION: Number of joins that API nodes have tried to push down, but failed		
	Ndb_pushed_queries_executed	
No	No	Yes
No	Global	No
DESCRIPTION: Number of joins successfully pushed down and executed on the data nodes		
	Ndb_pushed_reads	
No	No	Yes
No	Global	No
DESCRIPTION: Number of reads executed on the data nodes by pushed-down joins		
	ndb_report_thresh_binlog_epoch_slip	
Yes	No	No
Yes		No
DESCRIPTION: This is a threshold on the number of epochs to be behind before reporting binary log status		
	ndb_report_thresh_binlog_mem_usage	
Yes	No	No

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
Yes		No
DESCRIPTION: This is a threshold on the percentage of free memory remaining before reporting binary log status		
Ndb_scan_count		
No	No	Yes
No	Global	No
DESCRIPTION: The total number of scans executed by NDB since the cluster was last started		
ndb_table_no_logging		
No	Yes	No
No	Session	Yes
DESCRIPTION: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.		
ndb_table_temporary		
No	Yes	No
No	Session	Yes
DESCRIPTION: NDB tables are not persistent on disk: no schema files are created and the tables are not logged		
ndb_use_exact_count		
No	Yes	No
No	Both	Yes
DESCRIPTION: Use exact row count when planning queries		
ndb_use_transactions		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query		
ndb_version		
No	Yes	No
No	Global	No
DESCRIPTION: Shows build and NDB engine version as an integer.		
ndb_version_string		
No	Yes	No
No	Global	No
DESCRIPTION: Shows build information including NDB engine version in ndb-x.y.z format.		
ndbcluster		

Option or Variable Name

Notes		
Yes	No	No
Yes		No
DESCRIPTION: Enable NDB Cluster (if this version of MySQL supports it)		
Disabled by `--skip-ndbcluster`		
ndbinfo_database		
No	Yes	No
No	Global	No
DESCRIPTION: The name used for the NDB information database; read only.		
ndbinfo_max_bytes		
Yes	Yes	No
No	Both	Yes
DESCRIPTION: Used for debugging only.		
ndbinfo_max_rows		
Yes	Yes	No
No	Both	Yes
DESCRIPTION: Used for debugging only.		
ndbinfo_offline		
No	Yes	No
No	Global	Yes
DESCRIPTION: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views.		
ndbinfo_show_hidden		
Yes	Yes	No
No	Both	Yes
DESCRIPTION: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.		
ndbinfo_table_prefix		
Yes	Yes	No
No	Both	Yes
DESCRIPTION: The prefix to use for naming ndbinfo internal base tables		
ndbinfo_version		
No	Yes	No
No	Global	No
DESCRIPTION: The version of the ndbinfo engine; read only.		
server-id-bits		
Yes	Yes	No

Option or Variable Name		
Command Line	**System Variable**	**Status Variable**
Option File	**Scope**	**Dynamic**
Notes		
Yes	Global	No
DESCRIPTION: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.		
	`server_id_bits`	
Yes	Yes	No
Yes	Global	No
DESCRIPTION: The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value.		
	`slave_allow_batching`	
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Turns update batching on and off for a replication slave		
	`transaction_allow_batching`	
No	Yes	No
No	Session	Yes
DESCRIPTION: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.		

17.3.3 MySQL Cluster Configuration Files

Configuring MySQL Cluster requires working with two files:

- `my.cnf`: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.

- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the `config.ini` File.

Caching of configuration data. Beginning with MySQL Cluster NDB 6.4.0, MySQL Cluster uses *stateful configuration*. The global configuration file is no longer read every time the management server is restarted. Instead, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following items is true:

- **The management server is started using the --initial option.** When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the --reload option.** The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved,

but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.

- **The management server is started using --config-cache=FALSE.**   Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.

- **No configuration cache is found.**   In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

Configuration cache files.   Beginning with MySQL Cluster 6.4.0, the management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build MySQL Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache idenitifer. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

> **Note**
>
> It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the MySQL Cluster management server, see Section 17.4.4, "`ndb_mgmd` — The MySQL Cluster Management Server Daemon".

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.7, "How to Report Bugs or Problems".

17.3.3.1 MySQL Cluster Configuration: Basic Example

To support MySQL Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

> **Note**
>
> The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.1)

# enable ndbcluster storage engine, and provide connection string for
```

```
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see Section 17.3.3.3, "MySQL Cluster Connection Strings".)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

> **Important**
>
> Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design*.

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see MySQL Cluster System Variables.

The MySQL Cluster global configuration file is by convention named `config.ini` (but this is not required). It is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd` on the command line. Beginning with MySQL Cluster NDB 6.4.0, this option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for MySQL Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon ("`:`") as well as the equal sign ("`=`"); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. (Prior to MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Beginning with versions just stated, the default value is 2, which is the recommended setting in most common usage scenarios.) To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two SQL nodes is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first SQL node can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

> **Note**
>
> The preceding example is intended as a minimal starting configuration for purposes of familiarization with MySQL Cluster, and is almost certain not to be sufficient for production settings. See Section 17.3.3.2, "Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later", which provides more complete example starting configurations for use with MySQL Cluster NDB 6.2 and newer versions of MySQL Cluster.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

> **Note**
>
> Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the config.ini File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but be may used as a convenience when setting up a large cluster. See Section 17.3.3.4, "Defining Computers in a MySQL Cluster", for more information.

- `[ndbd]`: Defines a cluster data node (`ndbd` process). See Section 17.3.3.6, "Defining MySQL Cluster Data Nodes", for details.

- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 17.3.3.7, "Defining SQL and Other API Nodes in a MySQL Cluster".

- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 17.3.3.5, "Defining a MySQL Cluster Management Server".

- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 17.3.3.9, "MySQL Cluster TCP/IP Connections", for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 17.3.3.10, "MySQL Cluster TCP/IP Connections Using Direct Connections" to be of interest in some cases.)

- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.1, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 17.3.3.11, "MySQL Cluster Shared-Memory Connections".

- `[sci]`:Defines *Scalable Coherent Interface* connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialized hardware. See Section 17.3.3.12, "SCI Transport Connections in MySQL Cluster" for detailed information about SCI interconnects.

You can define `default` values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

17.3.3.2 Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later

Achieving the best performance from a MySQL Cluster depends on a number of factors including the following:

- MySQL Cluster software version

- Numbers of data nodes and SQL nodes

- Hardware

- Operating system

- Amount of data to be stored

- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each MySQL Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the MySQL Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide recommended base configurations for MySQL Cluster NDB 6.2 and 6.3 that can serve as reasonable starting points.

Starting configuration for MySQL Cluster NDB 6.2.   The following is a recommended starting point for configuring a cluster running MySQL Cluster NDB 6.2.

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-1-hostname
# NodeId=management-server-1-nodeid

[ndb_mgmd]
HostName=management-server-2-hostname

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a node ID for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.
```

```
# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
# newer on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000
TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
RedoBuffer=32M
# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include an Id for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=SQL-node-1-hostname
# NodeId=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (Id parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.
```

Starting configuration for MySQL Cluster NDB 6.3. The following is a recommended starting point for configuring a cluster running MySQL Cluster NDB 6.3. It is similar to the recommendation for MySQL Cluster NDB 6.2, with the addition of parameters for better control of NDBCLUSTER process threads.

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
```

```
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
# newer on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads (introduced in MySQL Cluster NDB 6.3.4) to achieve increased
# throughput when using ndbd. They are not needed when using ndbmtd; in
# particular, you should not set RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
checkpoint files and backup files to be compressed, which can result in a space
savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid
```

```
[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.
```

Recommended my.cnf options for SQL nodes. MySQL Servers acting as MySQL Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`

- `--ndb-index-stat-enable=0`

- `--ndb-force-send=1`

- `--engine-condition-pushdown=1`

17.3.3.3 MySQL Cluster Connection Strings

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node that is part of a MySQL Cluster requires a *connection string* that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]
```

`node_id` is an integer greater than or equal to 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):   "myhost1"
```

`localhost:1186` is used as the default connection string value if none is provided. If `port_num` is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/port-numbers for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. A MySQL Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

Beginning with MySQL Cluster NDB 6.3.19, it is also possible in a connection string to specify one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
    [bind-address=host-definition, ]
    host-definition[; bind-address=host-definition]
    host-definition[; bind-address=host-definition]
    [, ...]]

host-definition:
    host_name[:port_number]
```

If a single bind address is used in the connection string *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use 192.168.178.242 regardless of the management server to which it connects:

```
bind-address=192.168.178.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=192.168.178.242
```

In this case, the node uses localhost to connect to the management server running on the host named poseidon and 192.168.178.242 to connect to the management server running on the host named perch.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, localhost is used for connecting to the management server running on host poseidon; since 192.168.178.242 is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts perch and orca:

```
bind-address=192.168.178.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a [mysql_cluster] section in the management server's my.cnf file.

- For backward compatibility, two other options are available, using the same syntax:

  1. Set the NDB_CONNECTSTRING environment variable to contain the connection string.

  2. Write the connection string for each executable into a text file named Ndb.cfg and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

Previous to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the maximum length of a connection string was 1024 characters.

17.3.3.4 Defining Computers in a MySQL Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	string	[none]	...	IS

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

> **Important**
>
> The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	[none]	...	N

This is the computer's hostname or IP address.

17.3.3.5 Defining a MySQL Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

> **Note**
>
> If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	1 - 63	IS
NDB 6.1.1	unsigned	[none]	1 - 255	IS

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 63 inclusive (previous to MySQL Cluster NDB 6.1.1), or in the range 1 to

255 inclusive (MySQL Cluster NDB 6.1.1 and later). This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId` beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it now generates a warning.

- `NodeId`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	1 - 63	IS
NDB 6.1.1	unsigned	[none]	1 - 255	IS

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 63 inclusive (previous to MySQL Cluster NDB 6.1.1), or in the range 1 to 255 inclusive (MySQL Cluster NDB 6.1.1 and later). This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- `ExecuteOnComputer`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name	[none]	...	S

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

- `PortNumber`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	1186	0 - 64K	S

This is the port number on which the management server listens for configuration requests and management commands.

- HostName

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	[none]	...	N

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- LogDestination

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	{CONSOLE|SYSLOG|FILE}	[see text]	...	N

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

> **Note**
>
> Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

  - `filename`: The name of the log file.

    Prior to MySQL Cluster NDB 7.0.43 and MySQL Cluster NDB 7.1.23, the log file's default name, used if `FILE` was specified without also setting `filename`, was `logger.log`. Beginning with MySQL Cluster NDB 7.0.43 and MySQL Cluster NDB 7.1.23, the default log file name used in such cases is `ndb_nodeid_cluster.log`.

  - `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where N is the next number not yet used with this name.

  - `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the `FILE` parameter is `FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- `ArbitrationRank`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	0-2	1	0 - 2	N

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node will never be used as an arbitrator.

- `1`: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.

- `2`: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting `ArbitrationRank` to 0 on all management and SQL nodes. In MySQL Cluster NDB 7.0.7 and later releases, you can also control arbitration by overriding this parameter; to do this, set the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- `ArbitrationDelay`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	0	0 - 4294967039 (0xFFFFFEFF)	N

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `DataDir`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	path	.	...	N

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- `PortNumberStats`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	0 - 64K	N

This parameter specifies the port number used to obtain statistical information from a MySQL Cluster management server. It has no default value.

- **Wan**

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.1.1	boolean	false	true, false	N

Use WAN TCP setting as default. Introduced in MySQL Cluster NDB 6.1.1.

- **HeartbeatThreadPriority**

Beginning with MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, it is possible to use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first out) or `RR` (round robin). The policy value is followed optionally by the priority (an integer).

- **ExtraSendBufferMemory**

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.39	bytes	0	0 - 32G	N
NDB 7.1.28	bytes	0	0 - 32G	N

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

This parameter was added in MySQL Cluster NDB 7.0.39 and MySQL Cluster NDB 7.1.28. (Bug #14555359)

- **TotalSendBufferMemory**

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.0	bytes	0	256K - 4294967039 (0xFFFFFEFF)	N

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters".

- `HeartbeatIntervalMgmdMgmd`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.40	milliseconds	1500	100 - 4294967039 (0xFFFFFEFF)	N
NDB 7.1.29	milliseconds	1500	100 - 4294967039 (0xFFFFFEFF)	N

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

This parameter was added in MySQL Cluster NDB 7.0.40 and MySQL Cluster NDB 7.1.29. (Bug #16426805)

> **Note**
>
> After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.
>
> To add new management servers to a running MySQL Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 17.1.6.10, "Limitations Relating to Multiple MySQL Cluster Nodes".

17.3.3.6 Defining MySQL Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or (in MySQL Cluster NDB 6.4.0 and later) `ndbmtd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`, which must be defined in the local `[ndbd]` section.

- The parameter `NoOfReplicas`, which must be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes.

> **Note**
>
> It is no longer strictly necessary to set `NoOfReplicas` starting with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, where it acquires a default value (2). However, it remains good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where

present, `HostName`, `NodeId` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.) Parameter names and values are currently case-sensitive.

Information about configuration parameters specific to MySQL Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

Beginning with MySQL Cluster NDB 6.4.0, all of these parameters also apply to `ndbmtd` (the multi-threaded version of `ndbd`). Two additional data node configuration parameters —`MaxNoOfExecutionThreads` and `ThreadConfig`—apply to `ndbmtd` only; these have no effect when used with `ndbd`. For more information, see Multi-Threading Configuration Parameters (ndbmtd). See also Section 17.4.3, "ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)".

Identifying data nodes.   The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `Id`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	1 - 48	IS

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- `NodeId`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	1 - 48	IS

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- `ExecuteOnComputer`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name	[none]	...	S

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

- `HostName`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	localhost	...	N

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `ServerPort`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	1 - 64K	S

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

> **Note**
>
> Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`; see Section 17.3.3.5, "Defining a MySQL Cluster Management Server") so outgoing connections to that port from any data nodes should always be permitted.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

This parameter was added in MySQL Cluster NDB 6.2.0.

- `NodeGroup`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.0		[none]	0 - 65536	IS

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running MySQL Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 17.5.13.3, "Adding MySQL Cluster Data Nodes Online: Detailed Example".

This parameter was added in MySQL Cluster NDB 6.4.0.

- `NoOfReplicas`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	[none]	1 - 4	IS
NDB 6.3.25	integer	2	1 - 4	IS
NDB 7.0.6	integer	2	1 - 4	IS

This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

Prior to MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, there was no default value for `NoOfReplicas`; beginning with these versions, the default value is 2, which is the recommended setting in most common usage scenarios. (Bug #44746)

The maximum possible value is 4; *currently, only the values 1 and 2 are actually supported*.

> **Important**
>
> Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	path	.	...	IN

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	path	DataDir	...	IN

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

> **Note**
>
> This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	path	[see text]	...	IN

This parameter specifies the directory in which backups are placed.

> **Important**
>
> The string '`/BACKUP`' is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the *effective* default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster:

- `DataMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	80M	1M - 1024G	N

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes in MySQL 5.1, the data is stored on separate data pages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

Prior to MySQL Cluster NDB 7.0, the maximum record size was 8052 bytes; in MySQL Cluster NDB 7.0 and later, it is 14000 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

MySQL Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free `DataMemory`. This can also pose a problem with data node restarts on nodes that are heavily loaded with data. You can force `NDB` to create extra partitions for MySQL Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient. In MySQL Cluster 7.1.18 and later, you can also use the `MinFreePct` configuration parameter to help avoid problems with node restarts. (Bug #13436216)

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

In addition, due to the way in which new pages are allocated when the capacity of the current page is exhausted, there is an additional overhead of approximately 18.75%. When more `DataMemory` is required, more than one new page is allocated, according to the following formula:

```
number of new pages = FLOOR(number of current pages × 0.1875) + 1
```

For example, if 15 pages are currently allocated to a given table and an insert to this table requires additional storage space, the number of new pages allocated to the table is `FLOOR(15 × 0.1875) + 1 = FLOOR(2.8125) + 1 = 2 + 1 = 3`. Now 15 + 3 = 18 memory pages are allocated to the table. When the last of these 18 pages becomes full, `FLOOR(18 × 0.1875) + 1 = FLOOR(3.3750) + 1 = 3 + 1 = 4` new pages are allocated, so the total number of pages allocated to the table is now 22.

> **Note**
>
> The "18.75% + 1" overhead is no longer required beginning with MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones

- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure

- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2−4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	18M	1M - 1T	N

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. When defining a primary key or a unique index, two indexes are created, one of which is a hash index used for all tuple accesses as well as lock handling. This index is also used to enforce unique constraints.

You can estimate the size of a hash index using this formula:

```
size  = ( (fragments * 32K) + (rows * 18) )
          * replicas
```

fragments is the number of fragments, *replicas* is the number of replicas (normally 2), and *rows* is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

```
((8 * 32K) + (1000000 * 18)) * 2 = ((8 * 32768) + (1000000 * 18)) * 2
= (262144 + 18000000) * 2
= 18262144 * 2 = 36524288 bytes = ~35MB
```

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

- `StringMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	% or bytes	0	0 - 4294967039 (0xFFFFFEFF)	S
MySQL 5.1.32	% or bytes	25	0 - 4294967039 (0xFFFFFEFF)	S
MySQL 5.1.6	% or bytes	5	0 - 4294967039 (0xFFFFFEFF)	S
NDB 7.2.1	% or bytes	25	0 - 4294967039 (0xFFFFFEFF)	S

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between `0` and `100` inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than `100` is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum. (Previously, prior to MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.24, and MySQL Cluster NDB 7.0.5, the default value was 5; prior to MySQL 5.1.6, the default was 0.)

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 `Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error`, in which case you should increase this value. `25` (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

The only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is 2 × `DataMemory` for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that

such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

MinFreePct.   Beginning with MySQL Cluster NDB 7.0.29 and MySQL Cluster NDB 7.1.18, a proportion (5% by default) of data node resources including `DataMemory` and `IndexMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5) introduced in the same versions of MySQL Cluster.

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.29	unsigned	5	0 - 100	N
NDB 7.1.18	unsigned	5	0 - 100	N
NDB 7.2.3	unsigned	5	0 - 100	N

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction parameters.   The next few `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction`, added in MySQL Cluster NDB 7.0.26 and MySQL Cluster NDB 7.1.15, sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	4096	32 - 4294967039 (0xFFFFFEFF)	N

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to an SQL node requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for this parameter is

```
MaxNoOfConcurrentTransactions =
    (maximum number of tables accessed in any single transaction + 1)
    * number of cluster SQL nodes
```

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then 10 * 11 = 110 transaction records are required for this transaction, per SQL node, or 110 * 10 = 1100 transaction records total. Each data node can be expected to handle TotalNoOfConcurrentTransactions / number of data nodes. For a MySQL Cluster having 4 data nodes, this would mean setting `MaxNoOfConcurrentTransactions`

on each data node to 1100 / 4 = 275. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's MaxNoOfConcurrentTransactions is sufficient to cover a number of transaction equal to TotalNoOfConcurrentTransactions / number of node groups. If this cluster has a single node group, then `MaxNoOfConcurrentTransactions` should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for `MaxNoOfConcurrentTransactions` should always be no more than the value of `MaxNoOfConcurrentOperations`.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- `MaxNoOfConcurrentOperations`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	32K	32 - 4294967039 (0xFFFFFEFF)	N

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to `total number of concurrent operations / number of node groups`. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	UNDEFINED	32 - 4294967039 (0xFFFFFEFF)	N

By default, this parameter is calculated as 1.1 × `MaxNoOfConcurrentOperations`. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

- `MaxDMLOperationsPerTransaction`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.26	operations (DML)	4294967295	32 - 4294967295	N
NDB 7.1.15	operations (DML)	4294967295	32 - 4294967295	N

Added in MySQL Cluster NDB 7.0.26 and MySQL Cluster NDB 7.1.15, this parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set `MaxDMLOperationsPerTransaction` to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

Transaction temporary storage. The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- `MaxNoOfConcurrentIndexOperations`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	8K	0 - 4294967039 (0xFFFFFEFF)	N

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- `MaxNoOfFiredTriggers`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	4000	0 - 4294967039 (0xFFFFFEFF)	N

The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- `TransactionBufferMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	1M	1K - 4294967039 (0xFFFFFEFF)	N

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000 × 128 bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains 4000 × 16 = 62.5KB of buffer space. `Dbtc` is the module that handles transaction coordination.

Scans and buffering. There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to 10000 × 128 bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- `MaxNoOfConcurrentScans`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	256	2 - 500	N

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain MaxNoOfConcurrentScans scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of MaxNoOfConcurrentScans is 256. The maximum value is 500.

- MaxNoOfLocalScans

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	[see text]	32 - 4294967039 (0xFFFFFEFF)	N
NDB 7.2.0	integer	[see text]	32 - 4294967039 (0xFFFFFEFF)	N

Specifies the number of local scan records if many scans are not fully parallelized. In MySQL Cluster NDB 7.2.0 and later, when the number of local scan records is not provided, it is calculated as shown here:

```
4 * MaxNoOfConcurrentScans * [# data nodes] + 2
```

In MySQL Cluster NDB 7.1 and earlier, the default is calculated as the product of MaxNoOfConcurrentScans and the number of data nodes, plus 2. The minimum value is 32.

- BatchSizePerLocalScan

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	64	1 - 992	N
NDB 7.2.1	integer	256	1 - 992	N

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

BatchSizePerLocalScan has a strong connection to the BatchSize defined in the SQL nodes.

- LongMessageBuffer

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	1M	512K - 4294967039 (0xFFFFFEFF)	N
		2057		

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.4	bytes	4M	512K - 4294967039 (0xFFFFFEFF)	N
NDB 7.2.0	bytes	4M	512K - 4294967039 (0xFFFFFEFF)	N
NDB 7.1.31	bytes	64M	512K - 4294967039 (0xFFFFFEFF)	N

This is an internal buffer used for passing messages within individual nodes and between nodes. In MySQL Cluster NDB 6.4.3 and earlier, the default is 1MB; beginning with MySQL Cluster NDB 7.0.4, this increased to 4MB; the default increased to 64MB in MySQL Cluster NDB 7.1.31.

This parameter seldom needs to be changed from the default. However, when replicating a MySQL Cluster using `ndbmtd` for the data nodes, you may need to increase this value to 8MB (or possibly more) to prevent data node instability, because `ndbmtd` uses much more of this resource than `ndbd` does. Beginning with MySQL Cluster NDB 7.0.13 and MySQL Cluster NDB 7.1.2, this should no longer be necessary when using `ndbmtd` with MySQL Cluster Replication (Bug #46914).

- `MaxParallelScansPerFragment`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.23	bytes	32	1 - 4294967039 (0xFFFFFEFF)	N
NDB 7.1.12	bytes	32	1 - 4294967039 (0xFFFFFEFF)	N
NDB 7.2.0	bytes	256	1 - 4294967039 (0xFFFFFEFF)	N

Beginning with MySQL Cluster NDB 7.0.23 and MySQL Cluster NDB 7.1.12, it is possible to configure the maximum number of parallel scans (`TUP` scans and `TUX` scans) allowed before they begin queuing for serial handling. (Previously, the maximum number of parallel scans per fragment was fixed at 32.) You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

Beginning with MySQL Cluster NDB 7.2.0, the default value for this parameter is increased from 32 to 256.

Memory Allocation

`MaxAllocate`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.1.19	unsigned	32M	1M - 1G	N
NDB 6.2.3	unsigned	32M	1M - 1G	N
MySQL 5.1.20	unsigned	32M	1M - 1G	N

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where `NDB` gives `Out of memory` errors, but it is evident by examining the cluster logs or the output of `DUMP 1000` that all available memory has not yet been used, you can increase the value of this parameter (or `MaxNoOfTables`, or both) to cause `NDB` to make sufficient memory available.

This parameter was introduced in MySQL 5.1.20, MySQL Cluster NDB 6.1.12 and MySQL Cluster NDB 6.2.3.

Hash Map Size

`DefaultHashMapSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.38	LDM threads	240	0 - 3840	N
NDB 7.1.27	LDM threads	240	0 - 3840	N

Beginning with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.26, the size of the table hash maps used by `NDB` is configurable using this parameter; previously this value was hard-coded. `DefaultHashMapSize` can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table:

Value	Description / Effect
0	Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.
240	Original hash map size used by default in all MySQL Cluster NDB 7.1 and MySQL Cluster NDB 7.0 (and earlier) releases; effectively the only value prior to versions 7.0.38 and 7.1.26 (when this parameter was introduced).
3840	Larger hash map size available beginning with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.26

The primary intended use for this parameter is to facilitate upgrades and esecially downgrades between MySQL Cluster NDB 7.1 and later MySQL Cluster versions in which the larger hash map size (3840) is the default; by setting this parameter to 240 prior to performing an upgrade, you can cause the cluster to continue using the smaller size for table hash maps, in which case the tables remain compatible with earlier versions. `DefaultHashMapSize` can be set for individual data nodes, API nodes, or both, but setting it once only, in the `[ndbd default]` section of the `config.ini` file, is the recommended practice. You can also set this parameter to 0, in which case the default value is used.

After increasing this parameter, to have existing tables to take advantage of the new size, you can run `ALTER TABLE ... REORGANIZE PARTITION` on them, after which they can use the larger hash map size. This is in addition to performing a rolling restart, which makes the larger hash maps available to new tables, but does not enable existing tables to use them.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

Logging and checkpointing.   The following `[ndbd]` parameters control log and checkpoint behavior.

- `NoOfFragmentLogFiles`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	8	3 - 4294967039 (0xFFFFFEFF)	IN
MySQL 5.1.0	integer	16	3 - 4294967039 (0xFFFFFEFF)	IN

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the

first and last log files in the set (sometimes referred to as the "head" and "tail" log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A `REDO` log record is not removed until the required number of local checkpoints has been completed since that log record was inserted (prior to MySQL Cluster NDB 6.3.8, this was 3 local checkpoints; in later versions of MySQL Cluster, only 2 local checkpoints are necessary). Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

How these parameters interact and proposals for how to configure them are discussed in Section 17.3.3.13, "Configuring MySQL Cluster Parameters for Local Checkpoints".

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. Beginning with MySQL Cluster NDB 6.1.1, the size of the individual log files is configurable using the `FragmentLogFileSize` parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

> **Important**
>
> This parameter cannot be changed "on the fly"; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- `FragmentLogFileSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.1.11	bytes	16M	4M - 1G	IN

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when MySQL Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M. `FragmentLogFileSize` was added in MySQL Cluster NDB 6.1.11.

For more information about fragment log files, see the description for `NoOfFragmentLogFiles`.

- `InitFragmentLogFiles`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.19	[see values]	SPARSE	SPARSE, FULL	IN

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. Beginning with MySQL Cluster NDB 6.3.19, it is possible to override this behavior and force all bytes to be written regardless of the platform and file system type being used by mean of this parameter.

`InitFragmentLogFiles` takes one of two values:

- **SPARSE**. Fragment log files are created sparsely. This is the default value.

- **FULL**. Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the REDO log.

- MaxNoOfOpenFiles

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	40	20 - 4294967039 (0xFFFFFEFF)	N
MySQL 5.1.16	unsigned	0	20 - 4294967039 (0xFFFFFEFF)	N

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. (Prior to MySQL 5.1.16, the default was 40.) However, the minimum value to which this parameter can be set is 20.

- InitialNoOfOpenFiles

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.9	files	27	20 - 4294967039 (0xFFFFFEFF)	N

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- MaxNoOfSavedMessages

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	25	0 - 4294967039 (0xFFFFFEFF)	N

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- MaxLCPStartDelay

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.23	seconds	0	0 - 600	N
NDB 6.4.3	seconds	0	0 - 600	N

In parallel data node recovery (supported in MySQL Cluster NDB 6.3.8 and later), only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint

information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

Beginning with MySQL Cluster NDB 6.3.23 and MySQL Cluster NDB 6.4.3, it is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed.

To force such a delay, you can set `MaxLCPStartDelay`, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- `LcpScanProgressTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.40	second	60	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.1.29	second	60	0 - 4294967039 (0xFFFFFEFF)	N

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. Prior to MySQL Cluster NDB 7.0.39 and MySQL Cluster NDB 7.1.29, this interval is always 60 seconds (Bug #16630410). In MySQL Cluster NDB 7.0.39, MySQL Cluster NDB 7.1.29, and later this interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

Metadata objects.   The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as "suggestions" to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	1000	32 - 4294967039 (0xFFFFFEFF)	N

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

Prior to MySQL Cluster NDB 6.3.45, MySQL Cluster NDB 7.0.26, and MySQL Cluster NDB 7.1.15, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible (or not possible, depending on the circumstances) to create more than `MaxNoOfAttributes` attributes. (Bug #61684)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the MySQL Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be `6 * greatest_number_of_attributes = 600`.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	128	8 - 20320	N

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

Prior to MySQL Cluster NDB 6.3.45, MySQL Cluster NDB 7.0.26, and MySQL Cluster NDB 7.1.15, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible (or not possible, depending on the circumstances) to create more than `MaxNoOfTables` tables.

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

> **Note**
>
> The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfOrderedIndexes`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	128	0 - 4294967039 (0xFFFFFEFF)	N

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index

and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

> **Note**
>
> The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfUniqueHashIndexes`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	64	0 - 4294967039 (0xFFFFFEFF)	N

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

> **Note**
>
> The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfTriggers`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	768	0 - 4294967039 (0xFFFFFEFF)	N

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfIndexes`

This parameter is deprecated. You should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

- `MaxNoOfSubscriptions`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.2.10	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N
NDB 6.3.7	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N

Each `NDB` table in a MySQL Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter, which became available in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

- `MaxNoOfSubscribers`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.2.10	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N
NDB 6.3.7	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N

This parameter, added in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7, is of interest only when using MySQL Cluster Replication. The default value is 0, which is treated as `2 * MaxNoOfTables`; that is, there is one subscription per `NDB` table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three MySQL Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a master and as a slave, you should set `MaxNoOfSubscribers` equal to `3 * MaxNoOfTables`.

For more information, see Section 17.6, "MySQL Cluster Replication".

- `MaxNoOfConcurrentSubOperations`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.2.10	unsigned	256	0 - 4294967039 (0xFFFFFEFF)	N
NDB 6.3.7	unsigned	256	0 - 4294967039 (0xFFFFFEFF)	N

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

This parameter was added in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7.

Boolean parameters. The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- `LateAlloc`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.0	numeric	1	0 - 1	N

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

Added in MySQL Cluster NDB 6.4.0.

- `LockPagesInMainMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	numeric	0	0 - 2	N
MySQL 5.1.0	true|false (1|0)	0	0 - 1	N
MySQL 5.1.15	numeric	0	0 - 2	N

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, this parameter takes one of the integer values `0`, `1`, or `2`, which act as follows:

- `0`: Disables locking. This is the default value.

- `1`: Performs the lock after allocating memory for the process.

- `2`: Performs the lock before memory for the process is allocated.

Previously, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated.

> **Important**
>
> Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, it is no longer possible to use `true` or `false` for the value of this parameter; when upgrading from a previous version, you must change the value to `0`, `1`, or `2`.

Prior to MySQL Cluster NDB 6.3.31 and MySQL Cluster NDB 7.0.11, setting this parameter did not cause the stated memory to be allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. (Bug #37430)

> **Note**
>
> If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (`LockPagesInMainMemory` uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max`

> `locked memory`. For more information, see `ulimit -l` and http://linux.die.net/man/2/mlock).

> **Important**
>
> Beginning with `glibc` 2.10, `glibc` uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)
>
> The `glibc` behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to `glibc` 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)
>
> One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with `glibc`.

- `StopOnError`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	boolean	1	0, 1	N

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is `1`; this means that, by default, an error causes the data node process to halt.

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See Starting and Stopping the Agent on Linux, for more information.

- `CrashOnCorruptedTuple`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.28, 5.1.56-ndb-7.1.17	boolean	false	true, false	S
NDB 7.2.1	boolean	true	true, false	S

This parameter was introduced in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.17. When enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. By default, it is disabled.

- `Diskless`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	true|false (1|0)	false	true, false	IS

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using

diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `ODirect`

Effective Version	Type/Units	Default	Range/Values	**Restart Type**
NDB 6.1.11	boolean	false	true, false	N
NDB 6.2.3	boolean	false	true, false	N
NDB 6.3.0	boolean	false	true, false	N

Enabling this parameter causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using MySQL Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

This parameter was added in MySQL 5.1.20, MySQL Cluster NDB 6.1.11, MySQL Cluster NDB 6.2.3, and MySQL Cluster NDB 6.3.0.

`ODirect` is disabled by default.

- `RestartOnErrorInsert`

Effective Version	Type/Units	Default	Range/Values	**Restart Type**
MySQL 5.1.0	error code	2	0 - 4	N

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `CompressedBackup`

Effective Version	Type/Units	Default	Range/Values	**Restart Type**
NDB 6.3.7	boolean	false	true, false	N

Setting this parameter to `1` causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.

- `CompressedLCP`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.7	boolean	false	true, false	N

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

> ⚠️ **Important**
>
> You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	6000	70 - 4294967039 (0xFFFFFEFF)	N

To prevent the main thread from getting stuck in an endless loop at some point, a "watchdog" thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- `TimeBetweenWatchDogCheckInitial`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.20	milliseconds	6000	70 - 4294967039 (0xFFFFFEFF)	N

This is similar to the `TimeBetweenWatchDogCheck` parameter, except that `TimeBetweenWatchDogCheckInitial` controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

This parameter was added in MySQL 5.1.20.

- `StartPartialTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	30000	0 - 4294967039 (0xFFFFFEFF)	N

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- `StartPartitionedTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	60000	0 - 4294967039 (0xFFFFFEFF)	N

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If `StartPartitionedTimeout` is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- `StartFailureTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	0	0 - 4294967039 (0xFFFFFEFF)	N

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10−15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- `StartNoNodeGroupTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.24	milliseconds	15000	0 - 4294967039 (0xFFFFFEFF)	N

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then

treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is `15000` (that is, the management server waits 15 seconds). Setting this parameter equal to `0` means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

This parameter was added in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. See Section 17.5.13, "Adding MySQL Cluster Data Nodes Online", for more information.

- `HeartbeatIntervalDbDb`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	1500	10 - 4294967039 (0xFFFFFEFF)	N
NDB 7.2.0	milliseconds	5000	10 - 4294967039 (0xFFFFFEFF)	N

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

In MySQL Cluster NDB 7.2.0 and later, the default heartbeat interval is 5000 milliseconds (5 seconds). Previously, the default was 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency.

- `HeartbeatIntervalDbApi`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	1500	100 - 4294967039 (0xFFFFFEFF)	N

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared "dead," in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

- `HeartbeatOrder`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.35	numeric	0	0 - 65535	S

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.16	numeric	0	0 - 65535	S
NDB 7.1.5	numeric	0	0 - 65535	S

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle "dead" (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster.

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers `host1` and `host2`, and that these data nodes make up 2 node groups, as shown in the following table:

Node Group	Nodes Running on `host1`	Nodes Running on `host2`
Node Group 0:	Node A	Node B
Node Group 1:	Node C	Node D

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

Priot to MySQL Cluster NDB 6.3.35, MySQL Cluster NDB 7.0.16, and MySQL Cluster NDB 7.1.5, the order of heartbeat transmission between data nodes was always automatically determined by NDB. However, beginning with these versions, the `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable.

The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by NDB. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

Node	`HeartbeatOrder`
A	10
B	20

Node	**HeartbeatOrder**
C	30
D	25

To use this parameter to change the heartbeat transmission order in a running MySQL Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.

- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.1.13	milliseconds	1500	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.2.1	milliseconds	0	0 - 4294967039 (0xFFFFFEFF)	N

This parameter enables connection checking between data nodes. A data node that fails to respond within an interval of `ConnectCheckIntervalDelay` milliseconds is considered suspect, and is considered dead after two such intervals.

- `TimeBetweenLocalCheckpoints`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	number of 4-byte words, as a base-2 logarithm	20	0 - 31	N

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4×2^{20}) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- `TimeBetweenGlobalCheckpoints`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	2000	10 - 32000	N

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.2.0	milliseconds	2000	20 - 32000	N

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- `TimeBetweenEpochs`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.2.5	milliseconds	100	0 - 32000	N

This parameter defines the interval between synchronization epochs for MySQL Cluster Replication. The default value is 100 milliseconds.

`TimeBetweenEpochs` is part of the implementation of "micro-GCPs", which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- `TimeBetweenEpochsTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.22	milliseconds	4000	0 - 32000	N
MySQL 5.1.51	milliseconds	0	0 - 256000	N

This parameter defines a timeout for synchronization epochs for MySQL Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. In MySQL Cluster NDB 7.2.0 and later, the default value is 0; in other words, the timeout is disabled. This represents a change from previous versions of MySQL Cluster, in which the default value was 4000 milliseconds (4 seconds).

`TimeBetweenEpochsTimeout` is part of the implementation of "micro-GCPs", which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.7 and MySQL Cluster NDB 6.3.4.

The following changes regarding this parameter were made in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10:

- The maximum possible value for this parameter was increased from 32000 milliseconds to 256000 milliseconds.

- Setting this parameter to zero now has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both.

- The current value of this parameter and a warning are now written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP save takes longer than 10 seconds.

- `MaxBufferedEpochs`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.2.14	epochs	100	0 - 100000	N

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- `MaxBufferedEpochBytes`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.52	bytes	26214400	26214400 (0x01900000) - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.38	bytes	26214400	26214400 (0x01900000) - 4294967039 (0xFFFFFEFF)	N
NDB 7.1.27	bytes	26214400	26214400 (0x01900000) - 4294967039 (0xFFFFFEFF)	N

The total number of bytes allocated for buffering epochs by this node.

This parameter was introduced in MySQL Cluster NDB 6.3.52, MySQL Cluster NDB 7.0.38, and MySQL Cluster NDB 7.1.27. (Bug #16203623)

- `TimeBetweenInactiveTransactionAbortCheck`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	1000	1000 - 4294967039 (0xFFFFFEFF)	N

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- `TransactionInactiveTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	[see text]	0 - 4294967039 (0xFFFFFEFF)	N

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is `4G` (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- `TransactionDeadlockDetectionTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	1200	50 - 4294967039 (0xFFFFFEFF)	N

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is "dead"

- The operation has entered a lock queue

- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. In MySQL 5.1.10 and earlier versions, setting it too high could cause undesirable behavior in situations involving deadlocks and node failure. Beginning with MySQL 5.1.11, active transactions occurring during node failures are actively aborted by the MySQL Cluster Transaction Coordinator, and so high settings are no longer an issue with this parameter.

The default timeout value is 1200 milliseconds (1.2 seconds).

Prior to MySQL Cluster NDB versions 6.2.18, 6.3.24, and 7.0.5, the effective minimum for this parameter was 100 milliseconds. (Bug #44099) Beginning with these versions, the actual minimum is 50 milliseconds.

- `DiskSyncSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.12	bytes	4M	32K - 4294967039 (0xFFFFFEFF)	N

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of `TimeBetweenLocalCheckpoints`.

> **Note**
>
> When `ODirect` is enabled, it is not necessary to set `DiskSyncSize`; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

This parameter was added in MySQL 5.1.12.

- `DiskCheckpointSpeed`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.12	bytes	10M	1M - 4294967039 (0xFFFFFEFF)	N

The amount of data,in bytes per second, that is sent to disk during a local checkpoint. This allocation is shared by DML operations and backups (but not backup logging), which means that backups started during times of intensive DML may be impaired by flooding of the redo log buffer and may fail altogether if the contention is sufficiently severe.

The default value is 10M (10 megabytes per second).

This parameter was added in MySQL 5.1.12.

- `DiskCheckpointSpeedInRestart`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.12	bytes	100M	1M - 4294967039 (0xFFFFFEFF)	N

The amount of data,in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

This parameter was added in MySQL 5.1.12.

- `NoOfDiskPagesToDiskAfterRestartTUP`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	8K pages/100 milliseconds	40	1 - 4294967039 (0xFFFFFEFF)	N

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a "page" is defined as 8KB. This parameter is specified in units of 80KB per second, so setting `NoOfDiskPagesToDiskAfterRestartTUP` to a value of `20` entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. (See the entry for `IndexMemory` for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with `NoOfFragmentLogFiles`, `DataMemory`, and `IndexMemory`.

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see Section 17.3.3.13, "Configuring MySQL Cluster Parameters for Local Checkpoints".

The default value is 40 (3.2MB of data pages per second).

> **Note**
>
> This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeed` and `DiskSyncSize` instead.

- `NoOfDiskPagesToDiskAfterRestartACC`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	8K pages/100 milliseconds	20	1 - 4294967039 (0xFFFFFEFF)	N

This parameter uses the same units as `NoOfDiskPagesToDiskAfterRestartTUP` and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

> **Note**
>
> This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeed` and `DiskSyncSize`.

- `NoOfDiskPagesToDiskDuringRestartTUP` (DEPRECATED)

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	8K pages/100 milliseconds	40	1 - 4294967039 (0xFFFFFEFF)	N

This parameter is used in a fashion similar to `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

> **Note**
>
> This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize`.

- `NoOfDiskPagesToDiskDuringRestartACC` (DEPRECATED)

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	8K pages/100 milliseconds	20	1 - 4294967039 (0xFFFFFEFF)	N

2078

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

> **Note**
>
> This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize`.

- `ArbitrationTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	3000	10 - 4294967039 (0xFFFFFEFF)	N
NDB 7.2.0	milliseconds	7500	10 - 4294967039 (0xFFFFFEFF)	N

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

In MySQL Cluster NDB 7.2.0 and later, the default value is 7500 milliseconds (7.5 seconds). Previously, this was 3000 milliseconds (3 seconds).

- `Arbitration`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.7	enumeration	Default	Default, Disabled, WaitExternal	N

The `Arbitration` parameter, added in MySQL Cluster NDB 7.0.7, enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes. This is the default value.

- **Disabled.** Previously, it was possible to disable arbitration only by setting `ArbitrationRank` to 0 on all management and API nodes. Now, you can now use `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file to accomplish this task. In this case, any `ArbitrationRank` settings are ignored.

- **WaitExternal.** The `Arbitration` parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by `ArbitrationTimeout` has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that `ArbitrationTimeout` be 2 times as long as the interval required by the external cluster manager to perform arbitration.

> ⚠️ **Important**
>
> This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` is set to different values for individual data nodes.

Buffering and logging.   Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are "faked" by the `NDB` storage engine's file system abstraction layer.

- `UndoIndexBuffer`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	2M	1M - 4294967039 (0xFFFFFEFF)	N

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The `NDB` storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (`Index UNDO buffers overloaded`).

> ⚠️ **Important**
>
> It is not safe to decrease the value of this parameter during a rolling restart.

- `UndoDataBuffer`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	16M	1M - 4294967039 (0xFFFFFEFF)	N

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`Data UNDO buffers overloaded`).

> **Important**
>
> It is not safe to decrease the value of this parameter during a rolling restart.

- `RedoBuffer`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	8M	1M - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.4	bytes	32M	1M - 4294967039 (0xFFFFFEFF)	N

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a "fuzzy" checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

`RedoBuffer` sets the size of the buffer in which the REDO log is written. In MySQL Cluster NDB 6.4.3 and earlier, the default value is 8MB; beginning with MySQL Cluster NDB 7.0.4, the default is 32MB. The minimum value is 1MB.

If this buffer is too small, the `NDB` storage engine issues error code 1221 (`REDO log buffers overloaded`). For this reason, you should exercise care if you attempt to decrease the value of `RedoBuffer` as part of an online change in the cluster's configuration.

`ndbmtd` allocates a separate buffer for each LDM thread (see `ThreadConfig`). For example, with 4 LDM threads, an `ndbmtd` data node actually has 4 buffers and allocates `RedoBuffer` bytes to each one, for a total of `4 * RedoBuffer` bytes.

- `EventLogBufferSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.4	bytes	8192	0 - 64K	S

Controls the size of the circular buffer used for NDB log events within data nodes.

Added in MySQL Cluster NDB 7.0.4.

Controlling log messages.   In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16

possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `LogLevelStartup`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	1	0 - 15	N

The reporting level for events generated during startup of the process.

The default level is 1.

- `LogLevelShutdown`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	0	0 - 15	N

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- `LogLevelStatistic`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	0	0 - 15	N

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- `LogLevelCheckpoint`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	log level	0	0 - 15	N

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- `LogLevelNodeRestart`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	0	0 - 15	N

The reporting level for events generated during node restart.

The default level is 0.

- `LogLevelConnection`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	0	0 - 15	N

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- `LogLevelError`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	0	0 - 15	N

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- `LogLevelCongestion`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	levelr	0	0 - 15	N

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- `LogLevelInfo`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	integer	0	0 - 15	N

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- `MemReportFrequency`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.1.0	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N
MySQL 5.1.16	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the `DataMemory` and `IndexMemory`, respectively, set in the `config.ini` file. For

example, if `DataMemory` is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 17.5.6.2, "MySQL Cluster Log Events".

This parameter was added in MySQL Cluster 5.1.16 and MySQL Cluster NDB 6.1.0.

- `StartupStatusReportFrequency`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.0	seconds	0	0 - 4294967039 (0xFFFFFEFF)	N

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see Section 17.5.1, "Summary of MySQL Cluster Start Phases"). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time. Previous to MySQL Cluster NDB 6.4.0, only the beginning and end of the redo log file initialization process were logged. Beginning with this version, it is possible to force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

Debugging Parameters.   Beginning with MySQL Cluster NDB 6.3.36, MySQL Cluster NDB 7.0.17, and MySQL Cluster NDB 7.1.6, it is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value; currently, 0 (default - no logging) and 1 (logging enabled) are the only supported values.

Backup parameters.   The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	2M	0 - 4294967039 (0xFFFFFEFF)	N

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.23	bytes	16M	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.4	bytes	16M	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.5.1	bytes	16M	512K - 4294967039 (0xFFFFFEFF)	N

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

- `BackupLogBufferSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	2M	0 - 4294967039 (0xFFFFFEFF)	N
NDB 6.3.23	bytes	16M	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.4	bytes	16M	0 - 4294967039 (0xFFFFFEFF)	N

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 17.5.3.3, "Configuration for MySQL Cluster Backups".

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

- `BackupMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	4M	0 - 4294967039 (0xFFFFFEFF)	N

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.4	bytes	32M	0 - 4294967039 (0xFFFFFEFF)	N

This parameter is simply the sum of `BackupDataBufferSize` and `BackupLogBufferSize`.

In MySQL Cluster NDB 7.0.4 and later, the default value is 16MB + 16MB = 32MB. (Previously, it was 2MB + 2MB = 4MB.)

> **Important**
>
> If `BackupDataBufferSize` and `BackupLogBufferSize` taken together exceed the default value for `BackupMemory`, then this parameter must be set explicitly in the `config.ini` file to their sum.

- `BackupReportFrequency`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.2.3	seconds	0	0 - 4294967039 (0xFFFFFEFF)	N

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). `BackupReportFrequency` represents the time in seconds between backup status reports.

The default value is 0.

This parameter was added in MySQL Cluster NDB 6.2.3.

- `BackupWriteSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	32K	2K - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.4	bytes	256K	2K - 4294967039 (0xFFFFFEFF)	N

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 32KB; beginning with MySQL Cluster NDB 7.0.4, it is 256KB.

- `BackupMaxWriteSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	256K	2K - 4294967039 (0xFFFFFEFF)	N
MySQL 5.1.32	bytes	1M	2K - 4294967039 (0xFFFFFEFF)	N

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.2.1	bytes	1M	2K - 4294967039 (0xFFFFFEFF)	N

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 256KB; beginning with MySQL Cluster NDB 7.0.4, it is 1MB.

> **Important**
>
> When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`

- `BackupLogBufferSize >= BackupWriteSize + 16KB`

- `BackupMaxWriteSize >= BackupWriteSize`

MySQL Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts. They were introduced in MySQL Cluster NDB 6.3.4.

> **Note**
>
> To make use of these parameters, the data node process must be run as system root.

- `LockExecuteThreadToCPU`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.4	CPU ID	64K	0 - 64K	N

Previous to MySQL Cluster NDB 7.0. This parameter specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. The value of this parameter is an integer in the range 0 to 65535 (inclusive). The default is 65535.

MySQL Cluster NDB 7.0 and later (beginning with MySQL Cluster NDB 6.4.0). When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread.

When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive). The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter; beginning with in MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, you can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

Prior to MySQL Cluster NDB 7.0.18 and MySQL Cluster NDB 7.1.7, the effective maximum value recognized by this parameter as a valid CPU ID was 255; using a greater value caused thread locking to be disabled. (Bug #56185)

- LockMaintThreadsToCPU

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.4	CPU ID	64K	0 - 64K	N
NDB 6.4.0	CPU ID	[none]	0 - 64K	N

This parameter specifies the ID of the CPU assigned to handle NDBCLUSTER maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). This parameter was added in MySQL Cluster NDB 6.3.4. Prior to MySQL Cluster NDB 6.4.0, the default is 65535; in MySQL Cluster NDB 7.0 and later MySQL Cluster release series, there is no default value.

- RealtimeScheduler

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.4	boolean	false	true, false	N

Setting this parameter to 1 enables real-time scheduling of data node threads.

Prior to MySQL Cluster NDB 7.0.40 and MySQL Cluster NDB 7.1.29, this parameter did not work correctly with data nodes running ndbmtd. (Bug #16961971)

The default is 0 (scheduling disabled).

- SchedulerExecutionTimer

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.4	µs	50	0 - 11000	N

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

This parameter was added in MySQL Cluster NDB 6.3.4.

- SchedulerSpinTimer

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.4	µs	0	0 - 500	N

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

- BuildIndexThreads

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.30	numeric	0	0 - 128	S
NDB 7.0.11	numeric	0	0 - 128	S

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when the `MAX_ROWS` option has been used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multi-threaded building of ordered indexes.

This parameter was added in MySQL Cluster NDB 6.3.30 and MySQL Cluster NDB 7.0.11. Prior to MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, it was supported only when using `ndbd`; in these and later MySQL Cluster releases, `BuildIndexThreads` is also supported for data nodes running `ndbmtd` (see Bug #54521).

You can enable multi-threaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- `TwoPassInitialNodeRestartCopy`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.1.11	boolean	false	true, false	N

In MySQL Cluster NDB 7.1.11 and later, multi-threaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `TRUE`, which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

- `Numa`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.20	boolean	1	...	N
NDB 7.1.9	boolean	1	...	N

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating or by the data node process, whether the data node uses `ndbd` or `ndbmtd`. By default, `NDB` attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmtd`; this is because `nbdmtd` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.

Multi-Threading Configuration Parameters (ndbmtd). `ndbmtd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. In MySQL Cluster NDB 7.1.17 and later, a second method is also supported, whereby it is possible to set up more complex rules for `ndbmtd` multi-threading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multi-threaded data nodes.

- `MaxNoOfExecutionThreads`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.0	integer	[none]	2 - 8	IS
NDB 7.0.4	integer	2	2 - 8	IS

This parameter controls the number of execution threads used by `ndbmtd`, up to a maximum of 8 threads, 4 of which can be LDM (LQH) threads. Although this parameter is set in the `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmtd` and does not apply to `ndbd`.

Setting `MaxNoOfExecutionThreads` sets the number of threads by type as determined in the following table:

`MaxNoOfExecutionThreads` Value	LDM Threads	TC Threads	Send Threads	Receive Threads
0 .. 3	1	1	0	1
4 .. 6	2	1	0	1
7 .. 8	4	1	0	1

There is always one SUMA (replication) thread.

The thread types are described later in this section (see `ThreadConfig`).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line` *number*`: Illegal value` *value* `for parameter MaxNoOfExecutionThreads`.

For `MaxNoOfExecutionThreads`, a value of 0 or 1 is rounded up internally by `NDB` to 2, so that 2 is considered this parameter's default and minimum value.

`MaxNoOfExecutionThreads` is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use `ThreadConfig` instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multi-threaded data node process always spawns at least 4 threads, listed here:

- 1 local query handler (LDM) thread

- 1 transaction coordinator (TC) thread

- 1 receive thread

- 1 subscription manager (SUMA or replication) thread

Changing the number of LDM threads always requires a system restart, whether it is changed using this parameter or `ThreadConfig`. If the cluster's `IndexMemory` usage is greater than 50%, changing this requires an initial restart of the cluster. (A maximum of 30-35% `IndexMemory` usage is recommended in such cases.) Otherwise, resource usage and LDM thread allocation cannot be balanced between nodes, which can result in underutilized and overutilized LDM threads, and ultimately data node failures.

In MySQL Cluster NDB 7.1 and earlier, it is not possible to cause `ndbmtd` to use more than 1 TC thread. (This is possible in MySQL Cluster NDB 7.2.)

- `ThreadConfig`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.1.17	string	''	...	IS
NDB 7.2.3	string	''	...	IS

This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]

entry := type={param[,param[,...]]}

type := ldm | main | recv | rep | io | tc | watchdog

param := count=number
   | cpubind=cpu_list
   | cpuset=cpu_list
   | spintime=number
   | realtime={0|1}
```

The curly braces ({...}) surrounding the list of parameters are required, even if there is only one parameter in the list.

A _param_ (parameter) specifies any or all of the following information:

- The number of threads of the given type (`count`).

- The set of CPUs to which the threads of the given type are to be nonexclusively bound. Thsi is determined by either one of `cpubind` or `cpuset`). `cpubind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

  Only one of `cpubind` or `cpuset` can be provided in a single configuration.

- `spintime` determines the wait time in microseconds the thread spins before going to sleep.

  The default value for `spintime` is the value of the `SchedulerSpinTimer` data node configuration parameter.

  `spintime` does not apply to I/O threads or watchdog threads and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

The *type* attribute represents an NDB thread type. The thread types supported in MySQL Cluster NDB 7.1 and the range of permitted `count` values for each are provided in the following list:

- `ldm`: Local query handler (`DBLQH` kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. In MySQL Cluster NDB 7.1, the maximum is 4 such threads.

> ⚠️ **Important**
>
> Changing the number of LDM threads requires a system restart to be effective and safe for cluster operations. (This is also true when this is done using `MaxNoOfExecutionThreads`.) If `IndexMemory` usage is in excess of 50%, an initial restart of the cluster is required; a maximum of 30-35% `IndexMemory` usage is recommended in such cases. Otherwise, `IndexMemory` and `DataMemory` usage as well as the allocation of LDM threads cannot be balanced between nodes, which can ultimately lead to data node failures.

- `tc`: Transaction coordinator thread (`DBTC` kernel block) containing the state of an ongoing transaction. In MySQL Cluster NDB 7.1, there can be only 1 TC thread. (In MySQL Cluster NDB 7.2, this number is configurable.)

  Range: 1 only.

- `main`: Data dictionary and transaction coordinator (`DBDIH` and `DBTC` kernel blocks), providing schema management. This is always handled by a single dedicated thread.

  Range: 1 only.

- `recv`: Receive thread (`CMVMI` kernel block). Each receive thread handles one or more sockets for communicating with other nodes in a MySQL Cluster, with one socket per node. Previously, this was limited to a single thread, but MySQL Cluster 7.2 implements multiple receive threads (up to 8).

  Range: 1 only.

- `rep`: Replication thread (`SUMA` kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

  Range: 1 only.

- `io`: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

  Range: 1 only.

Simple examples:

```
# Example 1.

ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.
```

```
Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more CPUs for operating system and other tasks. Thus, for a host machine with 8 CPUs, you might want to use 8 CPU threads bound to 7 CPUs (leaving one for operating system and other functions), with 4 LDM threads, 1 TC thread, 1 receive thread, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 8.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=4,cpubind=1,2,3,4},main={cpubind=5}, \
io={cpubind=5},rep={cpubind=6},tc{cpubind=7},recv={cpubind=8}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

In MySQL Cluster NDB 7.1 and earlier, it is not possible to cause `ndbmtd` to use more than 1 TC thread; this capability is introduced in MySQL Cluster NDB 7.2.

Disk Data Configuration Parameters.   Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.6	bytes	64M	4M - 1T	N

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that Cluster Disk Data storage always uses N * 32 KB memory where N is some nonnegative integer.

The default value for this parameter is `64M` (2000 pages of 32 KB each).

This parameter was added in MySQL 5.1.6.

Beginning with MySQL Cluster NDB 7.1.9, you can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 17.5.10.8, "The ndbinfo diskpagebuffer Table", for more information.

- `SharedGlobalMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.2.0	bytes	128M	0 - 64T	N
MySQL 5.1.6	bytes	20M	0 - 64T	N

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, `UNDO` files, and

data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `UNDO_BUFFER_SIZE` option used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for this options by the setting of the `InitialLogFileGroup` data node configuration parameter. `SharedGlobalMemory` can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

As of MySQL Cluster NDB 7.2.0, the default value is `128M`. (Previously, this was `20M`.)

This parameter was added in MySQL 5.1.6.

- `DiskIOThreadPool`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.3	threads	8	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.7	threads	2	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.1.0	threads	2	0 - 4294967039 (0xFFFFFEFF)	N

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool`, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.**   You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set `DiskIOThreadPool` higher to enable separate threads to handle the files on each disk.

- **Disk performance and types.**   The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

This parameter was added in MySQL Cluster NDB 6.4.0. Previous to MySQL Cluster NDB 6.4.3, it was named `IOThreadPool`. Previous to MySQL Cluster NDB 7.0.7, the default value was 8. Beginning with MySQL Cluster NDB 7.0.7 and MySQL Cluster NDB 7.1.0, the default is 2.

- **Disk Data file system parameters.**   The parameters in the following list were added in MySQL Cluster NDB 6.2.17, 6.3.22, and 6.4.3 to make it possible to place MySQL Cluster Disk Data files in specific directories without the need for using symbolic links.

  - `FileSystemPathDD`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.22	filename	[see text]	...	IN

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.2.17	filename	[see text]	...	IN
NDB 6.4.3	filename	[see text]	...	IN

If this parameter is specified, then MySQL Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathDataFiles`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.22	filename	[see text]	...	IN
NDB 6.2.17	filename	[see text]	...	IN
NDB 6.4.3	filename	[see text]	...	IN

If this parameter is specified, then MySQL Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathUndoFiles`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.22	filename	[see text]	...	IN
NDB 6.2.17	filename	[see text]	...	IN
NDB 6.4.3	filename	[see text]	...	IN

If this parameter is specified, then MySQL Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see Section 17.5.12.1, "MySQL Cluster Disk Data Objects".

- **Disk Data object creation parameters.**   The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

  - `InitialLogFileGroup`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.22	string	[see text]	...	S
NDB 6.2.17	string	[see text]	...	S
NDB 6.4.3	string	[see text]	...	S

    This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

    ```
    InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

    file-specification-list:
        file-specification[; file-specification[; ...]]

    file-specification:
        filename:size
    ```

    The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

    Consider the following:

    ```
    InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
    ```

    This is equivalent to the following SQL statements:

    ```
    CREATE LOGFILE GROUP LG1
        ADD UNDOFILE 'undo1.log'
        INITIAL_SIZE 250M
        UNDO_BUFFER_SIZE 128M
        ENGINE NDBCLUSTER;

    ALTER LOGFILE GROUP LG1
        ADD UNDOFILE 'undo2.log'
        INITIAL_SIZE 150M
        ENGINE NDBCLUSTER;
    ```

    This logfile group is created when the data nodes are started with `--initial`.

    Resources for the initial log file group are taken from the global memory pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter; if this parameter is set too low and the values set in `InitialLogFileGroup` for the logfile group's initial size or undo buffer size are too high, the cluster may fail to create the default log file group when starting, or fail to start altogether.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of a MySQL Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.22	string	[see text]	...	S
NDB 6.2.17	string	[see text]	...	S
NDB 6.4.3	string	[see text]	...	S

This parameter can be used to specify a MySQL Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The `file-specification-list` uses the same syntax as shown with the `InitialLogfileGroup` parameter, the only difference being that each `file-specification` used with `InitialTablespace` corresponds to a data file. At least one must be specified in the `file-specification-list`. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of a MySQL Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
    ADD DATAFILE 'data1.dat'
    EXTENT_SIZE 8M
    INITIAL_SIZE 2G
    ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
    ADD DATAFILE 'data2.dat'
    INITIAL_SIZE 4G
    ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating MySQL Cluster Disk Data tables thereafter.

Disk Data and GCP Stop errors. Errors encountered when using Disk Data tables such as `Node nodeid killed this node because GCP stop was detected` (error 2303) are often referred to as "GCP stop errors". Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints`

tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition, adjusting the cluster configuration as discussed here can also help:

- **MySQL Cluster NDB 6.2 and 6.3.** When working with large amounts of data on disk under high load, the default value for `DiskPageBufferMemory` may not be large enough. In such cases, you should increase its value to include most of the memory available to the data nodes after accounting for index memory, data memory, internal buffers, and memory needed by the data node host operating system.

  You can use this formula as a guide:

  ```
  DiskPageBufferMemory
    = 0.8
      x (
          [total memory]
            - ([operating system memory] + [buffer memory] + DataMemory + IndexMemory)
        )
  ```

  Once you have established that sufficient memory is reserved for `DataMemory`, `IndexMemory`, NDB internal buffers, and operating system overhead, it is possible (and sometimes desirable) to allocate more than the above amount of the remainder to `DiskPageBufferMemory`.

- **MySQL Cluster NDB 7.X.** In addition to the considerations given for `DiskPageBufferMemory` as explained previously, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` data node configuration parameter determines the timeout for commits. However, beginning with MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10, it is possible to disable both types of timeouts by setting this parameter to 0.

Parameters for configuring send buffer memory allocation (MySQL Cluster NDB 7.0 and later).
Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The following data node configuration parameters were added in MySQL Cluster NDB 6.4.0 to permit the setting of limits on this memory allocation; this change is reflected by the addition of the configuration parameters `TotalSendBufferMemory` and `OverLoadLimit`, as well as a change in how the existing `SendBufferMemory` configuration parameter is used. For more information, see Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters".

- `ExtraSendBufferMemory`

  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

  This parameter was added in MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20. (Bug #13633845, Bug #11760629, Bug #53053)

- `TotalSendBufferMemory`

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

Prior to MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, this parameter did not work correctly with `ndbmtd`. (Bug #13633845)

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters".

- `ReservedSendBufferMemory`

  This parameter is present in `NDBCLUSTER` source code beginning with MySQL Cluster NDB 6.4.0. However, it is not currently enabled.

  As of MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, this parameter is deprecated, and is subject to removal in a future release of MySQL Cluster (Bug #11760629, Bug #53053).

For more detailed information about the behavior and use of `TotalSendBufferMemory` and `ReservedSendBufferMemory`, and about configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters".

> **Note**
>
> Previous to MySQL Cluster NDB 7.0, to add new data nodes to a MySQL Cluster, it was necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster (that is, you had to perform a system restart). All data node processes had to be started with the `--initial` option.
>
> Beginning with MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. See Section 17.5.13, "Adding MySQL Cluster Data Nodes Online", for more information.

Redo log over-commit handling. Beginning with MySQL Cluster NDB 7.1.10, it is possible to control the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- `RedoOverCommitCounter`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.1.10	numeric	3	0 - 4294967039 (0xFFFFFEFF)	N

  When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

`RedoOverCommitCounter` defaults to 3. Set it to 0 to disable the limit. This parameter was added in MySQL Cluster NDB 7.1.10.

- `RedoOverCommitLimit`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.1.10	seconds	20	0 - 4294967039 (0xFFFFFEFF)	N

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its `DefaultOperationRedoProblemAction` setting (it either queues the operations to be re-tried, or aborts them).

By default, `RedoOverCommitLimit` is 20 seconds. Set to 0 to disable checking for redo log flush timeouts. This parameter was added in MySQL Cluster NDB 7.1.10.

Controlling restart attempts.   Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to exercise more finely-grained control over restart attempts by data nodes when they fail to start using two data node configuration parameters added in these releases. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts, as described in the following list:

- `StartFailRetryDelay`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.37	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.18	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.1.7	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N
NDB 6.2.19	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N

Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Note

This parameter is ignored unless `StopOnError` is equal to 0.

- `MaxStartFailRetries`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.37	unsigned	3	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.18	unsigned	3	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.1.7	unsigned	3	0 - 4294967039 (0xFFFFFEFF)	N
NDB 6.2.19	unsigned	3	0 - 4294967039 (0xFFFFFEFF)	N

Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Note

This parameter is ignored unless `StopOnError` is equal to 0.

17.3.3.7 Defining SQL and Other API Nodes in a MySQL Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

Note

For a discussion of MySQL server options for MySQL Cluster, see MySQL Server Options for MySQL Cluster; for information about MySQL server system variables relating to MySQL Cluster, see MySQL Cluster System Variables.

- `Id`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	1 - 63	IS
NDB 6.1.1	unsigned	[none]	1 - 255	IS

The `Id` is an integer value used to identify the node in all cluster internal messages. Prior to MySQL Cluster NDB 6.1.1, the permitted range of values for this parameter was 1 to 63 inclusive. Beginning with MySQL Cluster NDB 6.1.1, the permitted range is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- `ConnectionMap`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.1.0	string	[none]	...	N

Specifies which data nodes to connect. Introduced in MySQL Cluster NDB 6.1.0.

- `NodeId`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	1 - 63	IS
NDB 6.1.1	unsigned	[none]	1 - 255	IS

The `NodeId` is an integer value used to identify the node in all cluster internal messages. Prior to MySQL Cluster NDB 6.1.1, the permitted range of values for this parameter was 1 to 63 inclusive. Beginning with MySQL Cluster NDB 6.1.1, the permitted range is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

> **Note**
>
> Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- `ExecuteOnComputer`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name	[none]	...	S

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

- `HostName`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	[none]	...	N

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding "slot" from any host which can establish a network connection to the management server host machine. *This differs from*

the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.

- `ArbitrationRank`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	0-2	0	0 - 2	N

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting `ArbitrationRank` to 0 on all management and SQL nodes. In MySQL Cluster NDB 7.0.7 and later releases, you can also control arbitration by overriding this parameter; to do this, set the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- `ArbitrationDelay`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	milliseconds	0	0 - 4294967039 (0xFFFFFEFF)	N

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- `BatchByteSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	32K	1024 - 1M	N
NDB 7.2.1	bytes	16K	1024 - 1M	N

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize`) and in terms of bytes (`BatchByteSize`). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 32K.

- `BatchSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	records	64	1 - 992	N
NDB 7.2.1	records	256	1 - 992	N

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- `ExtraSendBufferMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.39	bytes	0	0 - 4294967039 (0xFFFFFEFF)	N
NDB 7.1.28	bytes	0	0 - 4294967039 (0xFFFFFEFF)	N

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

This parameter was added in MySQL Cluster NDB 7.0.39 and MySQL Cluster NDB 7.1.28. (Bug #14555359)

- `HeartbeatThreadPriority`

Beginning with MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, it is possible to use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first in) or `RR` (round robin). This followed optionally by the priority (an integer).

- `MaxScanBatchSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	256K	32K - 16M	N

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- `TotalSendBufferMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.0	bytes	0	256K - 4294967039 (0xFFFFFEFF)	N

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters".

- `AutoReconnect`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.3.26	boolean	false	true, false	N
NDB 7.0.7	boolean	false	true, false	N

This parameter is available beginning with MySQL Cluster NDB 6.3.26 and MySQL Cluster NDB 7.0.7. By default, its value is `false`, which forces disconnected API nodes (including MySQL Servers acting as SQL nodes) the use a new connection to the cluster rather than attempting to re-use an existing one, which can cause problems when using dynamically-allocated node IDs. (Bug #45921)

Note

This parameter can be overridden using the NDB API. For more information, see Ndb_cluster_connection::set_auto_reconnect(), and Ndb_cluster_connection::get_auto_reconnect().

- `DefaultOperationRedoProblemAction`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.1.10	enumeration	ABORT	ABORT, QUEUE	S
NDB 7.2.1	enumeration	ABORT	ABORT, QUEUE	S

This parameter was introduced in MySQL Cluster NDB 7.1.10 (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) for controlling the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- `ABORT`: Any pending operations from aborted transactions are also aborted.

- `QUEUE`: Pending operations from transactions that were aborted are queued up to be re-tried.

Prior to MySQL Cluster NDB 7.1.26, setting this parameter did not have any effect. (Bug #15855588)

- `DefaultHashMapSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.0.38	buckets	240	0 - 3840	N
NDB 7.1.27	buckets	240	0 - 3840	N

Beginning with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.26, the size of the table hash maps used by `NDB` is configurable using this parameter; previously this value was hard-coded. `DefaultHashMapSize` can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

Value	Description / Effect
0	Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.

Value	Description / Effect
240	Original hash map size used by default in all MySQL Cluster NDB 7.1 and MySQL Cluster NDB 7.0 (and earlier) releases; effectively the only value prior to versions 7.0.38 and 7.1.26 (when this parameter was introduced).
3840	Larger hash map size available beginning with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.26

The primary intended use for this parameter is to facilitate upgrades and especially downgrades between MySQL Cluster NDB 7.1 and later MySQL Cluster versions in which the larger hash map size (3840) is the default; by setting this parameter to 240 prior to performing an upgrade, you can cause the cluster to continue using the smaller size for table hash maps, in which case the tables remain compatible with earlier versions. `DefaultHashMapSize` can be set for individual data nodes, API nodes, or both, but setting it once only, in the `[ndbd default]` section of the `config.ini` file, is the recommended practice. You can also set this parameter to 0, in which case the default value is used.

After increasing this parameter, to have existing tables to take advantage of the new size, you can run `ALTER TABLE ... REORGANIZE PARTITION` on them, after which they can use the larger hash map size. This is in addition to performing a rolling restart, which makes the larger hash maps available to new tables, but does not enable existing tables to use them.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

- Wan

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.1.1	boolean	false	true, false	N

Use WAN TCP setting as default. Introduced in MySQL Cluster NDB 6.1.1.

You can also obtain information from a MySQL server running as a MySQL Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----------------------------+---------------+
| Variable_name               | Value         |
+-----------------------------+---------------+
| Ndb_cluster_node_id         | 5             |
| Ndb_config_from_host        | 192.168.0.112 |
| Ndb_config_from_port        | 1186          |
| Ndb_number_of_storage_nodes | 4             |
+-----------------------------+---------------+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see MySQL Cluster Status Variables.

> **Note**
>
> To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

> It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

17.3.3.8 MySQL Server Options and Variables for MySQL Cluster

This section provides information about MySQL server options, server and status variables that are specific to MySQL Cluster. For general information on using these, and for other options and variables not specific to MySQL Cluster, see Section 5.1, "The MySQL Server".

For MySQL Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 17.3, "Configuration of MySQL Cluster NDB 6.1-7.1".

MySQL Server Options for MySQL Cluster

This section provides descriptions of `mysqld` server options relating to MySQL Cluster. For information about `mysqld` options not specific to MySQL Cluster, and for general information about the use of options with `mysqld`, see Section 5.1.3, "Server Command Options".

For information about command-line options used with other MySQL Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs". For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see Section 17.4, "MySQL Cluster Programs".

- `--ndb-batch-size=#`

Table 17.10 Type and value information for ndb-batch-size

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-batch-size`		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	integer	32768 / 0 - 31536000
DESCRIPTION: Size (in bytes) to use for NDB transaction batches		

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-blob-read-batch-bytes=bytes`

Table 17.11 Type and value information for ndb-blob-read-batch-bytes

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-blob-read-batch-bytes`		

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	integer	65536 / 0 - 4294967295
DESCRIPTION: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.		

This option can be used to set the size (in bytes) for batching of `BLOB` data reads in MySQL Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be read within the current transaction, any pending `BLOB` read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` read batching.

> **Note**
>
> In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

This option was introduced in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10.

- `--ndb-blob-write-batch-bytes=bytes`

Table 17.12 Type and value information for ndb-blob-write-batch-bytes

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-blob-write-batch-bytes`		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	integer	65536 / 0 - 4294967295
DESCRIPTION: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.		

This option can be used to set the size (in bytes) for batching of `BLOB` data writes in MySQL Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be written within the current transaction, any pending `BLOB` write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` write batching.

> **Note**
>
> In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

This option was introduced in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10.

- `--ndb-cluster-connection-pool=#`

Table 17.13 Type and value information for ndb-cluster-connection-pool

Command Line	System Variable	Status Variable
Option File	**Scope**	**Dynamic**
From Version	**Type**	**Default, Range**
Notes		
`ndb-cluster-connection-pool`		
Yes	Yes	Yes
Yes	Global	No
MySQL 5.1	integer	1 / 1 - 63
DESCRIPTION: Number of connections to the cluster used by MySQL		

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

> **Important**
>
> Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.
>
> Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

This option was introduced in MySQL Cluster NDB 6.2.2. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13, the value used for this option is available as a system variable (Bug #35573).

Prior to MySQL Cluster NDB 7.0.23 and MySQL Cluster NDB 7.1.12, there was also a status variable corresponding to this option; however, the status variable was removed as redundant as of these versions. (Bug #60119)

- `--ndb-connectstring=connection_string`

Table 17.14 Type and value information for ndb-connectstring

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-connectstring`		
Yes	No	No
Yes		No
MySQL 5.1	string	
DESCRIPTION: Point to the management server that distributes the cluster configuration		

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See Section 17.3.3.3, "MySQL Cluster Connection Strings", for syntax.

- `--ndb-deferred-constraints=[0|1]`

Table 17.15 Type and value information for ndb-deferred-constraints

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-deferred-constraints`		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	integer	0 / 0 - 1
DESCRIPTION: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.		

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. `0` is the default.

This option is not normally needed for operation of MySQL Cluster or MySQL Cluster Replication, and is intended primarily for use in testing.

This option was added in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.14.

- `--ndb-distribution=[KEYHASH|LINHASH]`

Table 17.16 Type and value information for ndb-distribution

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb-distribution		
Yes	Yes	No
Yes	Global	Yes
MySQL 5.1	enumeration	KEYHASH / LINHASH, KEYHASH
DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)		

Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

- `--ndb-mgmd-host=host[:port]`

Table 17.17 Type and value information for ndb-mgmd-host

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb-mgmd-host		
Yes	No	No
Yes		No
MySQL 5.1	string	localhost:1186
DESCRIPTION: Set the host (and port, if desired) for connecting to management server		

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndbcluster`

Table 17.18 Type and value information for ndbcluster

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndbcluster		
Yes	No	No

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
Yes		No
MySQL 5.1	boolean	FALSE
DESCRIPTION: Enable NDB Cluster (if this version of MySQL supports it)		
Disabled by `--skip-ndbcluster`		

The `NDBCLUSTER` storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-log-apply-status`

Table 17.19 Type and value information for ndb-log-apply-status

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-log-apply-status`		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	boolean	OFF
DESCRIPTION: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.		

Causes a slave `mysqld` to log any updates received from its immediate master to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the master. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as slaves of the current `mysqld`.

In a chain replication setup, using this option allows downstream (slave) clusters to be aware of their positions relative to all of their upstream contributors (masters).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating MySQL Cluster. This also allows a cluster acting as a master to see when its changes (epochs) have been applied to the other clusters in the circle.

This option was added in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10. It has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[0|1]`

Table 17.20 Type and value information for ndb-log-empty-epochs

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-log-empty-epochs`		
Yes	Yes	No
Yes	Global	Yes
MySQL 5.1	boolean	OFF
DESCRIPTION: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.		

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index` (Bug #49559, Bug #11757505).

Because `--ndb-log-empty-epochs=1` causes the size of `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

This option was introduced in MySQL Cluster NDB 6.3.21 and MySQL Cluster NDB 6.4.1. Prior to MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.3, setting `--ndb-log-empty-epochs=0` also caused no row to be written in `ndb_binlog_index` for an empty epoch.

- `--ndb-log-orig`

Table 17.21 Type and value information for ndb-log-orig

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-log-orig`		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	boolean	OFF
DESCRIPTION: Log originating server id and epoch in mysql.ndb_binlog_index table.		

Log the originating server ID and epoch in the `ndb_binlog_index` table.

Note that this makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see Section 17.6.4, "MySQL Cluster Replication Schema and Tables".

- `--ndb-log-transaction-id`

Table 17.22 Type and value information for ndb-log-transaction-id

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb-log-transaction-id		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	boolean	OFF
DESCRIPTION: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.		

Causes a slave `mysqld` to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, `--log-bin-use-v1-row-events` must be set to `FALSE` in order to use this option.

This option is available beginning with MySQL Cluster NDB 7.1.16 (and is not supported in mainline MySQL Server 5.1). It is required to enable MySQL Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function introduced in the same MySQL Cluster release.

The default value is `FALSE`.

For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `--ndb-nodeid=#`

Table 17.23 Type and value information for ndb-nodeid

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb-nodeid		
Yes	No	Yes
Yes	Global	No
5.0.45	integer	/ 1 - 63
5.1.5	integer	/ 1 - 255
DESCRIPTION: MySQL Cluster node ID for this MySQL server		

Set this MySQL server's node ID in a MySQL Cluster.

Prior to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option can be used *instead* of specifying the node ID as part of the connection string or in the `config.ini` file, or permitting the cluster to determine an arbitrary node ID. If you use this option, then `--ndb-nodeid` must be specified

before `--ndb-connectstring`. If `--ndb-nodeid` is used *and* a node ID is specified in the connection string, then the MySQL server cannot connect to the cluster.

Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the `--ndb-nodeid` option *overrides* any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition (regardless of the MySQL Cluster version), if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an "open" `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for MySQL Cluster SQL nodes, see Section 17.3.3.7, "Defining SQL and Other API Nodes in a MySQL Cluster".

- `--ndb_optimization_delay=milliseconds`

Table 17.24 Type and value information for ndb_optimization_delay

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb_optimization_delay`		
No	Yes	No
No	Global	Yes
MySQL 5.1	integer	10 / 0 - 100000
DESCRIPTION: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.		

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on `NDB` tables. The default is 10.

- `ndb-transid-mysql-connection-map=state`

Table 17.25 Type and value information for ndb-transid-mysql-connection-map

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-transid-mysql-connection-map`		
Yes	No	No
No		No
MySQL 5.1	enumeration	ON / ON, OFF, FORCE

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
DESCRIPTION: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name.		

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. `FORCE` keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

This option was added in MySQL Cluster NDB 7.1.17.

- `--ndb-wait-connected=`*seconds*

Table 17.26 Type and value information for ndb-wait-connected

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb-wait-connected`		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	integer	0 / 0 - 31536000
5.1.56-ndb-7.1.16, 5.1.56-ndb-7.0.27	integer	30 / 0 - 31536000
DESCRIPTION: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.		

This option sets the period of time that the MySQL server waits for connections to MySQL Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, there existed a hard-coded 30-second timeout (which was removed in these versions), and the default value for this option was `0`. Starting with these releases, the default value is `30`, and user-supplied values are handled correctly. (Bug #12543299)

- `--ndb-wait-setup=`*seconds*

Table 17.27 Type and value information for ndb-wait-setup

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb-wait-setup		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	integer	15 / 0 - 31536000
5.1.56-ndb-7.0.27, 5.1.56-ndb-7.1.16	integer	30 / 0 - 31536000
DESCRIPTION: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete.		

This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, the default value for this option was 15. In these and later releases, the default value is 30. (Bug #12543299)

- --server-id-bits=#

Table 17.28 Type and value information for server-id-bits

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
server-id-bits		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	integer	32 / 7 - 32
DESCRIPTION: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.		

This option indicates the number of least significant bits within the 32-bit server_id which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the AnyValue of an OperationOptions structure (MySQL Cluster uses the AnyValue to store the server ID).

When extracting the effective server ID from server_id for purposes such as detection of replication loops, the server ignores the remaining bits. The --server-id-bits option is used to mask out any irrelevant bits of server_id in the IO and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `--server-id-bits` option set to 32 (the default).

The value of `server_id` must be less than 2 ^ `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable was added in MySQL Cluster NDB 7.0.17 and MySQL Cluster NDB 7.1.6; it is supported only in these and later releases of MySQL Cluster. It is not supported by the standard MySQL Server.

- `--skip-ndbcluster`

Table 17.29 Type and value information for skip-ndbcluster

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`skip-ndbcluster`		
Yes	No	No
Yes		No
DESCRIPTION: Disable the NDB Cluster storage engine		

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See Section 17.3.1, "Quick Test Setup of MySQL Cluster", for an example.

MySQL Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to MySQL Cluster and the `NDB` storage engine. For system variables not specific to MySQL Cluster, see Section 5.1.4, "Server System Variables". For general information on using system variables, see Section 5.1.5, "Using System Variables".

- `have_ndbcluster`

Table 17.30 Type and value information for have_ndbcluster

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`have_ndbcluster`		
No	Yes	No
No	Global	No
MySQL 5.1	boolean	
DESCRIPTION: Whether mysqld supports NDB Cluster tables (set by --ndbcluster option)		

`YES` if `mysqld` supports `NDBCLUSTER` tables. `DISABLED` if `--skip-ndbcluster` is used.

This variable is deprecated and is removed in MySQL 5.6. Use `SHOW ENGINES` instead.

- `ndb_autoincrement_prefetch_sz`

Table 17.31 Type and value information for ndb_autoincrement_prefetch_sz

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb_autoincrement_prefetch_sz`		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	integer	32 / 1 - 256
5.0.56	integer	1 / 1 - 256
5.1.1	integer	32 / 1 - 256
5.1.23	integer	1 / 1 - 256
5.1.16-ndb-6.2.0	integer	32 / 1 - 256
5.1.23-ndb-6.2.10	integer	1 / 1 - 256
5.1.19-ndb-6.3.0	integer	32 / 1 - 256
5.1.23-ndb-6.3.7	integer	1 / 1 - 256
5.1.41-ndb-6.3.31	integer	1 / 1 - 65536
5.1.30-ndb-6.4.0	integer	32 / 1 - 256
5.1.41-ndb-7.0.11	integer	1 / 1 - 65536
DESCRIPTION: NDB auto-increment prefetch size		

Determines the probability of gaps in an autoincremented column. Set it to `1` to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. The minimum value is 1. Prior to MySQL 5.1.23, MySQL Cluster NDB 6.2.9, and MySQL Cluster NDB 6.3.7, the default value was 32; in these and all later versions, the default is 1. Prior to MySQL Cluster NDB 6.3.31 and MySQL Cluster NDB 7.0.11, the maximum value was 256; in these and all later versions of MySQL Cluster (including all MySQL Cluster NDB 7.1 releases), the maximum is 65536 (Bug #50621).

Beginning with MySQL Cluster NDB 6.2.10, MySQL Cluster NDB 6.3.7, and MySQL 5.1.23, this variable affects the number of `AUTO_INCREMENT` IDs that are fetched between statements only. Within a statement, at least 32 IDs are now obtained at a time. Also beginning with these releases, the default value is 1. (Bug #31956)

> **Important**
>
> This variable does not affect inserts performed using `INSERT ... SELECT`.

- `ndb_cache_check_time`

Table 17.32 Type and value information for ndb_cache_check_time

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_cache_check_time		
Yes	Yes	No
Yes	Global	Yes
MySQL 5.1	integer	0 / -
DESCRIPTION: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache		

The number of milliseconds that elapse between checks of MySQL Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- ndb_deferred_constraints

Table 17.33 Type and value information for ndb_deferred_constraints

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_deferred_constraints		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	integer	0 / 0 - 1
DESCRIPTION: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.		

Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable was added in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.14.

This variable is not normally needed for operation of MySQL Cluster or MySQL Cluster Replication, and is intended primarily for use in testing.

- ndb_distribution

Table 17.34 Type and value information for ndb_distribution

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_distribution		
Yes	Yes	No
Yes	Global	Yes
MySQL 5.1	enumeration	KEYHASH / LINHASH, KEYHASH
DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)		

Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

- ndb_eventbuffer_max_alloc

Table 17.35 Type and value information for ndb_eventbuffer_max_alloc

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_eventbuffer_max_alloc		
Yes	Yes	No
Yes	Global	Yes
MySQL 5.1	integer	0 / 0 - 4294967295
DESCRIPTION: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).		

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

This variable was added in MySQL Cluster NDB 7.1.29.

- ndb_extra_logging

Table 17.36 Type and value information for ndb_extra_logging

From Version	Type	Default, Range
Notes		
Yes	Yes	No
Yes	Global	Yes
MySQL 5.1	integer	0 / -
5.1.19-ndb-6.3.0	integer	1 / -
DESCRIPTION: Controls logging of MySQL Cluster schema, connection, and data distribution events in the MySQL error log		

This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log.

This variable was added in MySQL 5.1.6. Prior to MySQL Cluster NDB 6.3, the default value was 0; in MySQL Cluster NDB 6.3.0 and later, the default is 1.

- ndb_force_send

Table 17.37 Type and value information for ndb_force_send

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_force_send		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	boolean	TRUE
DESCRIPTION: Forces sending of buffers to NDB immediately, without waiting for other threads		

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- ndb_index_stat_cache_entries

Table 17.38 Type and value information for ndb_index_stat_cache_entries

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_index_stat_cache_entries		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	integer	32 / 0 - 4294967295
DESCRIPTION: Sets the granularity of the statistics by determining the number of starting and ending keys		

Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queried directly. Default value: `32`.

> **Note**
>
> If `ndb_index_stat_enable` is `OFF`, then setting this variable has no effect.

This variable is deprecated as of MySQL 5.1.19, and is removed from MySQL Cluster NDB 7.1.31 and later.

- ndb_index_stat_enable

Table 17.39 Type and value information for ndb_index_stat_enable

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_index_stat_enable		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	boolean	OFF
DESCRIPTION: Use NDB index statistics in query optimization		

Use NDB index statistics in query optimization. Defaults to `OFF` prior to MySQL Cluster NDB 7.2; `ON` is the default in MySQL Cluster NDB 7.2 and later.

- ndb_index_stat_option

Table 17.40 Type and value information for ndb_index_stat_option

Command Line	System Variable	Status Variable
Option File	**Scope**	**Dynamic**
From Version	**Type**	**Default, Range**
Notes		
ndb_index_stat_option		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	string	loop_enable=1000ms,loop_idle=1000ms,loop_b update_batch=1,read_batch=4,idle_batch=32,c check_delay=10m,delete_batch=8, clean_delay=1m,error_batch=4, error_delay=1m,evict_batch=8,evict_delay=1m, cache_lowpct=90,zero_total=0
5.1.56-ndb-7.1.17	string	loop_checkon=1000ms,loop_idle=1000ms,loop_ update_batch=1,read_batch=4,idle_batch=32,c check_delay=1m,delete_batch=8,clean_delay= error_delay=1m,evict_batch=8,evict_delay=1m, cache_lowpct=90
DESCRIPTION: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces		

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values. Note that this list must not contain any space characters.

Options not used when setting ndb_index_stat_option are not changed from their default values. For example, you can set ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'.

Time values can be optionally suffixed with h (hours), m (minutes), or s (seconds). Millisecond values can optionally be specified using ms; millisecond values cannot be specified using h, m, or s.) Integer values can be suffixed with K, M, or G.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

Name	Description	Default/Units	Minimum/Maximum
loop_enable		1000 ms	0/4G
loop_idle	Time to sleep when idle	1000 ms	0/4G
loop_busy	Time to sleep when more work is waiting	100 ms	0/4G
update_batch		1	0/4G
read_batch		4	1/4G
idle_batch		32	1/4G

Name	Description	Default/Units	Minimum/Maximum
check_batch		8	1/4G
check_delay	How often to check for new statistics	10 m	1/4G
delete_batch		8	0/4G
clean_delay		1 m	0/4G
error_batch		4	1/4G
error_delay		1 m	1/4G
evict_batch		8	1/4G
evict_delay	Clean LRU cache, from read time	1 m	0/4G
cache_limit	Maximum amount of memory in bytes used for cached index statistics by this mysqld; clean up the cache when this is exceeded.	32 M	0/4G
cache_lowpct		90	0/100
zero_total	Setting this to 1 causes all accumulating counters in ndb_index_stat_status to be reset to 0. Note that the option value is also reset to 0 when this is done.	0	0/1

ndb_index_stat_option was added in MySQL Cluster NDB 7.1.15.

- ndb_index_stat_update_freq

Table 17.41 Type and value information for ndb_index_stat_update_freq

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_index_stat_update_freq		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	integer	20 / 0 - 4294967295
DESCRIPTION: How often to query data nodes instead of the statistics cache		

How often to query data nodes instead of the statistics cache. For example, a value of 20 (the default) means to direct every 20th query to the data nodes.

> **Note**
>
> If `ndb_index_stat_cache_entries` is `0`, then setting this variable has no effect; in this case, every query is sent directly to the data nodes.

This variable is deprecated as of MySQL 5.1.19, and is removed from MySQL Cluster NDB 7.1.31 and later.

- `ndb_join_pushdown`

Table 17.42 Type and value information for ndb_join_pushdown

Command Line	System Variable	Status Variable
Option File	**Scope**	**Dynamic**
From Version	**Type**	**Default, Range**
Notes		
`ndb_join_pushdown`		
No	Yes	No
No	Both	Yes
5.1.51-ndb-7.2.0	boolean	TRUE
DESCRIPTION: Enables pushing down of joins to data nodes		

Added in MySQL Cluster NDB 7.2.0, this variable controls whether joins on `NDB` tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of `NDB` by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

Conditions for NDB pushdown joins.   In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type.

    This means that expressions such as `t1.a = t2.a + constant` cannot be pushed down, and that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.

3. Explicit locking is not supported; however, the `NDB` storage engine's characteristic implicit row-based locking is enforced.

    This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref`, `eq_ref`, or `const` access methods, or some combination of these methods.

    Outer joined child tables can only be pushed using `eq_ref`.

If the root of the pushed join is an `eq_ref` or `const`, only child tables joined by `eq_ref` can be appended. (A table joined by `ref` is likely to become the root of another pushed join.)

If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by `[LINEAR] HASH`, `LIST`, or `RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```
mysql> EXPLAIN
    ->       SELECT e.first_name, e.last_name, t.title, d.dept_name
    ->           FROM employees e
    ->           JOIN dept_emp de ON e.emp_no=de.emp_no
    ->           JOIN departments d ON d.dept_no=de.dept_no
    ->           JOIN titles t ON e.emp_no=t.emp_no\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: d
         type: ALL

          ref: employees.de.emp_no
         rows: 19
        Extra: Child of 'e' in pushed join@1
```

```
4 rows in set (0.00 sec)
```

> **Note**
>
> If inner joined child tables are joined by `ref`, *and* the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads` (all introduced in MySQL Cluster NDB 7.2.0).

2. The counters in the `ndbinfo.counters` table that belong to the `DBSPJ` kernel block. (These counters and the `DBSPJ` block were also introduced in MySQL Cluster NDB 7.2.0). See Section 17.5.10.7, "The ndbinfo counters Table", for information about these counters. See also The DBSPJ Block, in the *MySQL Cluster API Developer Guide*.

- `ndb_log_apply_status`

Table 17.43 Type and value information for ndb_log_apply_status

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb_log_apply_status`		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	boolean	OFF
DESCRIPTION: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID.		

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

This variable was added in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10.

- `ndb_log_bin`

Table 17.44 Type and value information for ndb_log_bin

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb_log_bin`		
Yes	Yes	No
No	Both	Yes

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
MySQL 5.1	boolean	ON
DESCRIPTION: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.		

Causes updates to `NDB` tables to be written to the binary log. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. `ndb_log_bin` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

This variable was added in MySQL 5.1.6.

- `ndb_log_binlog_index`

Table 17.45 Type and value information for ndb_log_binlog_index

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb_log_binlog_index`		
Yes	Yes	No
No	Global	Yes
MySQL 5.1	boolean	ON
DESCRIPTION: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.		

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to `1` (`ON`); normally, there is never any need to change this value in a production environment.

This variable was added in MySQL 5.1.6.

- `ndb_log_empty_epochs`

Table 17.46 Type and value information for ndb_log_empty_epochs

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb_log_empty_epochs`		
Yes	Yes	No
Yes	Global	Yes

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
MySQL 5.1	boolean	OFF
DESCRIPTION: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.		

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index` (Bug #49559, Bug #11757505).

- `ndb_log_orig`

Table 17.47 Type and value information for ndb_log_orig

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb_log_orig`		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	boolean	OFF
DESCRIPTION: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.		

Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

This variable was added in MySQL Cluster NDB 6.3.2.

- `ndb_log_transaction_id`

Table 17.48 Type and value information for ndb_log_transaction_id

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb_log_transaction_id`		
No	Yes	No
No	Global	No
MySQL 5.1	boolean	OFF
DESCRIPTION: Whether NDB transaction IDs are written into the binary log. (Read-only.)		

This read-only, Boolean system variable shows whether a slave `mysqld` writes NDB transaction IDs in the binary log (required to use "active-active" MySQL Cluster Replication with `NDB$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is available in MySQL Cluster NDB 7.1.16 and later. It is not supported in mainline MySQL Server 5.1.

For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `ndb_optimized_node_selection`

Table 17.49 Type and value information for ndb_optimized_node_selection

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndb_optimized_node_selection`		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	boolean	ON
5.1.22-ndb-6.3.4	integer	3 / 0 - 3
DESCRIPTION: Determines how an SQL node chooses a cluster data node to use as transaction coordinator		

Prior to MySQL Cluster NDB 6.3.4.   Causes an SQL node to use the "closest" data node as transaction coordinator. Enabled by default. Set to `0` or `OFF` to disable, in which case the SQL node uses each data node in the cluster in succession. When this option is disabled each SQL thread attempts to use a given data node 8 times before proceeding to the next one.

Beginning with MySQL Cluster NDB 6.3.4.   There are two forms of optimized node selection, described here:

1. The SQL node uses *promixity* to determine the transaction coordinator; that is, the "closest" data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be "closest" to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`; SCI connection; TCP connection from a host other than `localhost`.

2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values `0`, `1`, `2`, or `3`. `3` is the default. These values affect node selection as follows:

- `0`: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node. (This is the same "round-robin" behavior as caused by setting this option to `0` or `OFF` in previous versions of MySQL Cluster.)

- 1: Proximity to the SQL node is used to determine the transaction coordinator. (This is the same behavior as caused by setting this option to 1 or ON in previous MySQL versions.)

- 2: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.

- 3: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior in MySQL Cluster NDB 6.3.4 and later.)

> **Important**
>
> Beginning with MySQL Cluster NDB 6.3.4, it is no longer possible to set --ndb_optimized_node_selection to ON or OFF; attempting to do so causes mysqld to abort with an error.

- ndb_report_thresh_binlog_epoch_slip

Table 17.50 Type and value information for ndb_report_thresh_binlog_epoch_slip

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_report_thresh_binlog_epoch_slip		
Yes	No	No
Yes		No
MySQL 5.1	integer	3 / 0 - 256
DESCRIPTION: This is a threshold on the number of epochs to be behind before reporting binary log status		

This is a threshold on the number of epochs to be behind before reporting binary log status. For example, a value of 3 (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binary log is 3 or more, a status message is sent to the cluster log.

- ndb_report_thresh_binlog_mem_usage

Table 17.51 Type and value information for ndb_report_thresh_binlog_mem_usage

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_report_thresh_binlog_mem_usage		
Yes	No	No
Yes		No

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
MySQL 5.1	integer	10 / 0 - 10
DESCRIPTION: This is a threshold on the percentage of free memory remaining before reporting binary log status		

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of `10` (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

- ndb_table_no_logging

Table 17.52 Type and value information for ndb_table_no_logging

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_table_no_logging		
No	Yes	No
No	Session	Yes
MySQL 5.1	boolean	FALSE
DESCRIPTION: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.		

When this variable is set to `ON` or `1`, it causes `NDB` tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when ndb_table_no_logging is enabled, and continues to apply for the lifetime of the table, even if ndb_table_no_logging is later changed. Suppose that `A`, `B`, `C`, and `D` are tables that we create (and perhaps also alter), and that we also change the setting for ndb_table_no_logging as shown here:

```
SET @@ndb_table_no_logging = 1;

CREATE TABLE A ... ENGINE NDB;

CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;

ALTER TABLE B ENGINE NDB;

SET @@ndb_table_no_logging = 0;

CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;

SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables `A` and `B` are not checkpointed; `A` was created with `ENGINE NDB` and B was altered to use `NDB`, both while `ndb_table_no_logging` was enabled. However, tables `C` and `D` are logged; `C` was altered to use `NDB` and `D` was created using `ENGINE NDB`, both while `ndb_table_no_logging` was disabled. Setting `ndb_table_no_logging` back to `1` or `ON` does *not* cause table `C` or `D` to be checkpointed.

> **Note**
>
> `ndb_table_no_logging` has no effect on the creation of `NDB` table schema files; to suppress these, use `ndb_table_temporary` instead.

- `ndb_table_temporary`

Table 17.53 Type and value information for ndb_table_temporary

Command Line	System Variable	Status Variable
Option File	**Scope**	**Dynamic**
From Version	**Type**	**Default, Range**
Notes		
`ndb_table_temporary`		
No	Yes	No
No	Session	Yes
MySQL 5.1	boolean	FALSE
DESCRIPTION: NDB tables are not persistent on disk: no schema files are created and the tables are not logged		

When set to `ON` or `1`, this variable causes `NDB` tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

> **Note**
>
> Setting this variable currently has no effect in MySQL Cluster NDB 7.0 and later. This is a known issue; see Bug #34036.

- `ndb_use_copying_alter_table`

Table 17.54 Type and value information for ndb_use_copying_alter_table

Command Line	System Variable	Status Variable
Option File	**Scope**	**Dynamic**
From Version	**Type**	**Default, Range**
Notes		
`ndb_use_copying_alter_table`		
No	Yes	No
No	Both	No
DESCRIPTION: Use copying ALTER TABLE operations in MySQL Cluster		

Forces `NDB` to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

This variable was added in MySQL 5.1.12.

- ndb_version

Table 17.55 Type and value information for ndb_version

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range

No	Global	No
MySQL 5.1	string	
DESCRIPTION: Shows build information including NDB engine version in ndb-x.y.z format.		

NDB engine version in ndb-*x.y.z* format.

This variable was added in MySQL Cluster NDB 7.1.19.

- ndb_use_exact_count

Table 17.57 Type and value information for ndb_use_exact_count

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_use_exact_count		

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
No	Yes	No
No	Both	Yes
MySQL 5.1	boolean	ON
5.1.47-ndb-7.1.8	boolean	OFF
DESCRIPTION: Use exact row count when planning queries		

Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query. Prior to MySQL Cluster NDB 7.1.7, the default value for this variable was ON. Starting with MySQL Cluster NDB 7.1.8, the value of ndb_use_exact_count defaults to OFF, which allows for faster queries overall.

- ndb_use_transactions

Table 17.58 Type and value information for ndb_use_transactions

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndb_use_transactions		
Yes	Yes	No
Yes	Both	Yes
MySQL 5.1	boolean	ON
DESCRIPTION: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query		

You can disable NDB transaction support by setting this variable's values to OFF (not recommended). The default is ON.

> **Note**
>
> The setting for this variable was not honored in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. (Bug #43236)

- server_id_bits

Table 17.59 Type and value information for server_id_bits

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
server_id_bits		
Yes	Yes	No
Yes	Global	No
MySQL 5.1	integer	32 / 7 - 32
DESCRIPTION: The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value.		

The effective value of `server_id` if the server was started with the `--server-id-bits` option set to a nondefault value.

If the value of `server_id` is greater than or equal to 2 to the power of `server_id_bits`, `mysqld` refuses to start.

This system variable was added in MySQL Cluster NDB 7.0.17 and MySQL Cluster NDB 7.1.6; it is supported only in these and later releases of MySQL Cluster. `server_id_bits` is not supported by the standard MySQL Server.

- `slave_allow_batching`

Table 17.60 Type and value information for slave_allow_batching

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
slave_allow_batching		
Yes	Yes	No
Yes	Global	Yes
MySQL 5.1	boolean	off
DESCRIPTION: Turns update batching on and off for a replication slave		

Whether or not batched updates are enabled on MySQL Cluster replication slaves.

This variable is available beginning with MySQL Cluster NDB 6.2.3. It is available for `mysqld` only as supplied with MySQL Cluster or built from the MySQL Cluster sources. For more information, see Section 17.6.6, "Starting MySQL Cluster Replication (Single Replication Channel)".

- `transaction_allow_batching`

Table 17.61 Type and value information for transaction_allow_batching

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
transaction_allow_batching		
No	Yes	No
No	Session	Yes
MySQL 5.1	boolean	FALSE
DESCRIPTION: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.		

When set to `1` or `ON`, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to `0` or `OFF`; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the "before" image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

> **Important**
>
> `transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable was added in MySQL Cluster NDB 6.3.7, and is currently supported in MySQL Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database. They were added in MySQL Cluster NDB 7.1.1.

- `ndbinfo_database`

Table 17.62 Type and value information for ndbinfo_database

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
ndbinfo_database		
No	Yes	No
No	Global	No
MySQL 5.1	string	ndbinfo
DESCRIPTION: The name used for the NDB information database; read only.		

Shows the name used for the `NDB` information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time; you can set it by starting the server using `--`

`ndbinfo-database=`*name*, which sets the value shown for this variable but does not actually change the name used for the NDB information database.

- `ndbinfo_max_bytes`

Table 17.63 Type and value information for ndbinfo_max_bytes

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndbinfo_max_bytes`		
Yes	Yes	No
No	Both	Yes
MySQL 5.1	integer	0 / -
DESCRIPTION: Used for debugging only.		

Used in testing and debugging only.

- `ndbinfo_max_rows`

Table 17.64 Type and value information for ndbinfo_max_rows

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndbinfo_max_rows`		
Yes	Yes	No
No	Both	Yes
MySQL 5.1	integer	10 / -
DESCRIPTION: Used for debugging only.		

Used in testing and debugging only.

- `ndbinfo_offline`

Table 17.65 Type and value information for ndbinfo_offline

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndbinfo_offline`		
No	Yes	No
No	Global	Yes

2139

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
MySQL 5.1	boolean	OFF
DESCRIPTION: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views.		

Place the `ndbinfo` database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in `NDB`. No rows are returned from such tables (or views).

- `ndbinfo_show_hidden`

Table 17.66 Type and value information for ndbinfo_show_hidden

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndbinfo_show_hidden`		
Yes	Yes	No
No	Both	Yes
MySQL 5.1	boolean	OFF
DESCRIPTION: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.		

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

- `ndbinfo_table_prefix`

Table 17.67 Type and value information for ndbinfo_table_prefix

Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
From Version	Type	Default, Range
Notes		
`ndbinfo_table_prefix`		
Yes	Yes	No
No	Both	Yes
MySQL 5.1	string	ndb$
DESCRIPTION: The prefix to use for naming ndbinfo internal base tables		

The prefix used in naming the ndbinfo database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is "`ndb$`". You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and

does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- `ndbinfo_version`

  Table 17.68 Type and value information for ndbinfo_version

Command Line	System Variable	Status Variable
Option File	**Scope**	**Dynamic**
From Version	**Type**	**Default, Range**
Notes		
`ndbinfo_version`		
No	Yes	No
No	Global	No
MySQL 5.1	string	
DESCRIPTION: The version of the ndbinfo engine; read only.		

  Shows the version of the `ndbinfo` engine in use; read-only.

MySQL Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to MySQL Cluster and the `NDB` storage engine. For status variables not specific to MySQL Cluster, and for general information on using status variables, see Section 5.1.6, "Server Status Variables".

- `Handler_discover`

  The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_event_bytes_count`

  The number of bytes of events received by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_bytes_sent_count_session`

  Amount of data (in bytes) sent to the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_bytes_sent_count_slave`

  Amount of data (in bytes) sent to the data nodes by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_bytes_sent_count`

  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_bytes_received_count_session`

  Amount of data (in bytes) received from the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_bytes_received_count_slave`

  Amount of data (in bytes) received from the data nodes by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_bytes_received_count`

  Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_event_bytes_count_injector`

  The number of bytes of events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_event_data_count_injector`

  The number of row change events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_event_data_count`

  The number of row change events received by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_event_nondata_count_injector`

  The number of events received, other than row change events, by the NDB binary log injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_event_nondata_count`

  The number of events received, other than row change events, by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_pk_op_count_session`

  The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_pk_op_count_slave`

  The number of operations by this slave based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_pk_op_count`

  The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_pruned_scan_count_session`

  The number of scans in this client session that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_pruned_scan_count_slave`

  The number of scans by this slave that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_pruned_scan_count`

  The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_range_scan_count_session`

  The number of range scans that have been started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_range_scan_count_slave`

  The number of range scans that have been started by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_range_scan_count`

  The number of range scans that have been started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_read_row_count_session`

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_read_row_count_slave`

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_read_row_count`

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_scan_batch_count_session`

  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_scan_batch_count_slave`

  The number of batches of rows received by this slave. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_scan_batch_count`

  The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_table_scan_count_session`

  The number of table scans that have been started in this client session, including scans of internal tables,.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_table_scan_count_slave`

  The number of table scans that have been started by this slave, including scans of internal tables,.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_table_scan_count`

The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_abort_count_session`

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_abort_count_slave`

The number of transactions aborted by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_abort_count`

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_close_count_session`

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_close_count_slave`

The number of transactions closed by this slave. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_close_count`

  The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_commit_count_session`

  The number of transactions committed in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_commit_count_slave`

  The number of transactions committed by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_commit_count`

  The number of transactions committed by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_local_read_row_count_session`

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_local_read_row_count_slave`

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_local_read_row_count`

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_start_count_session`

  The number of transactions started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_start_count_slave`

  The number of transactions started by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_start_count`

  The number of transactions started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_uk_op_count_session`

  The number of operations in this client session based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_uk_op_count_slave`

  The number of operations by this slave based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_uk_op_count`

  The number of operations by this MySQL Server (SQL node) based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_exec_complete_count_session`

  The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_exec_complete_count_slave`

  The number of times a thread has been blocked by this slave while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_exec_complete_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_meta_request_count_session`

The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_meta_request_count_slave`

The number of times a thread has been blocked by this slave waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_meta_request_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_nanos_count_session`

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_nanos_count_slave`

Total time (in nanoseconds) spent by this slave waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_nanos_count`

Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_scan_result_count_session`

The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_scan_result_count_slave`

The number of times a thread has been blocked by this slave while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_scan_result_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, "NDB API Statistics Counters and Variables".

- `Ndb_cluster_node_id`

If the server is acting as a MySQL Cluster node, then the value of this variable its node ID in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

- `Ndb_config_from_host`

  If the server is part of a MySQL Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

  If the server is not part of a MySQL Cluster, then the value of this variable is an empty string.

  Prior to MySQL 5.1.12, this variable was named `Ndb_connected_host`.

- `Ndb_config_from_port`

  If the server is part of a MySQL Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

  If the server is not part of a MySQL Cluster, then the value of this variable is 0.

  Prior to MySQL 5.1.12, this variable was named `Ndb_connected_port`.

- `Ndb_conflict_fn_max`

  Used in MySQL Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to "greatest timestamp wins" conflict resolution since the last time that this `mysqld` was started.

  This variable was added in MySQL Cluster NDB 6.3.3. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `Ndb_conflict_fn_old`

  Used in MySQL Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of "same timestamp wins" conflict resolution on a given `mysqld` since the last time it was restarted.

  This variable was added in MySQL Cluster NDB 6.3.4. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `Ndb_conflict_fn_epoch`

  Used in MySQL Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `Ndb_conflict_fn_epoch_trans`

  Used in MySQL Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `Ndb_conflict_trans_row_conflict_count`

  Used in MySQL Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

  Currently, the only transactional conflict detection function supported by MySQL Cluster is NDB$EPOCH_TRANS(), so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `Ndb_conflict_trans_row_reject_count`

  Used in MySQL Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `Ndb_conflict_trans_reject_count`

  Used in MySQL Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `Ndb_conflict_trans_detect_iter_count`

  Used in MySQL Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `Ndb_conflict_trans_conflict_commit_count`

  Used in MySQL Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

- `Ndb_execute_count`

  Provides the number of round trips to the `NDB` kernel made by operations. Added in MySQL Cluster NDB 6.3.6.

- `Ndb_number_of_data_nodes`

  If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

Prior to MySQL 5.1.12, this variable was named `Ndb_number_of_storage_nodes`.

- `Ndb_pushed_queries_defined`

  The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes. Note that joins tested using `EXPLAIN` that can be pushed down contribute to this number. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pushed_queries_dropped`

  The number of joins that were pushed down to the NDB kernel but that could not be handled there. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pushed_queries_executed`

  The number of joins successfully pushed down to `NDB` and executed there. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pushed_reads`

  The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down. Note that executing `EXPLAIN` on joins that can be pushed down to `NDB` does not add to this number. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pruned_scan_count`

  This variable holds a count of the number of scans executed by `NDBCLUSTER` since the MySQL Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

  Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

  This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

- `Ndb_scan_count`

  This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the MySQL Cluster was last started.

  This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

- `Slave_heartbeat_period`

  Shows the replication heartbeat interval (in seconds) on a replication slave.

  This variable was added in MySQL Cluster NDB 6.3.4.

- `Slave_received_heartbeats`

  This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

  This variable was added in MySQL Cluster NDB 6.3.4.

17.3.3.9 MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in a MySQL Cluster. Normally it is not necessary to define TCP/IP connections; MySQL Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

> **Note**
>
> For an exception to this rule, see Section 17.3.3.10, "MySQL Cluster TCP/IP Connections Using Direct Connections".

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two MySQL Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

> **Important**
>
> Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the MySQL Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

*   `NodeId1`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	numeric	[none]	...	N

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 17.3.3.7, "Defining SQL and Other API Nodes in a MySQL Cluster".

*   `NodeId2`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	numeric	[none]	...	N

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 17.3.3.7, "Defining SQL and Other API Nodes in a MySQL Cluster".

*   `HostName1`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	[none]	...	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `HostName2`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	[none]	...	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `OverloadLimit`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.0	bytes	0	0 - 4294967039 (0xFFFFFEFF)	N

Beginning in MySQL Cluster NDB 6.4.0, this parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters", for more information.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, the effective value of this parameter was limited by the size of `SendBufferMemory`; beginning with these releases, the actual value for `OverloadLimit` (up to the stated maximum of 4G) is used instead.

- `SendBufferMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	256K	64K - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.4	unsigned	2M	256K - 4294967039 (0xFFFFFEFF)	N

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

Prior to MySQL Cluster NDB 7.0, this parameter determines a fixed amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 6.4.0, if this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in MySQL Cluster NDB 7.0 and later, see Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters".

In MySQL Cluster NDB 6.4.3 and earlier, the default size of the send buffer was 256 KB; in MySQL Cluster NDB 7.0.4 and later, it is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- `SendSignalId`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	boolean	[see text]	true, false	N

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- Checksum

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	boolean	false	true, false	N

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- PortNumber (*OBSOLETE*)

This formerly specified the port number to be used for listening for connections from other nodes. This parameter is deprecated as of MySQL 5.1.3 and should no longer be used; use the `ServerPort` data node configuration parameter for this purpose instead.

- ReceiveBufferMemory

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	64K	16K - 4294967039 (0xFFFFFEFF)	N
NDB 7.0.4	bytes	2M	16K - 4294967039 (0xFFFFFEFF)	N

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

In MySQL Cluster NDB 6.4.3 and earlier, the default value of this parameter was 64 KB; beginning with MySQL Cluster NDB 7.0.4, 2MB is the default. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- TCP_RCV_BUF_SIZE

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.1.1	unsigned	70080	1 - 2G	N

Determines the size of the receive buffer set during TCP transporter initialization. The default is recommended for most common usage cases.

`TCP_RCV_BUF_SIZE` was added in MySQL Cluster NDB 6.1.1.

- TCP_SND_BUF_SIZE

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.1.1	unsigned	71540	1 - 2G	N

Determines the size of the send buffer set during TCP transporter initialization. The default is recommended for most common usage cases.

`TCP_SND_BUF_SIZE` was added in MySQL Cluster NDB 6.1.1.

- `TCP_MAXSEG_SIZE`

Effective Version	Type/Units	Default	Range/Values	**Restart Type**
NDB 6.1.1	unsigned	0	0 - 2G	N

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

`TCP_MAXSEG_SIZE` was added in MySQL Cluster NDB 6.1.1.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

This parameter was added in MySQL Cluster NDB 6.2.0.

17.3.3.10 MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
```

```
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

17.3.3.11 MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2`, and `ShmKey`. All other parameters have default values that should work well in most cases.

> **Important**
>
> *SHM functionality is considered experimental only.* It is not officially supported in any current MySQL Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.
>
> For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- `NodeId1`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	numeric	[none]	...	N

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `NodeId2`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	numeric	[none]	...	N

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `HostName1`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	[none]	...	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `HostName2`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	[none]	...	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `OverloadLimit`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.0	bytes	0	0 - 4294967039 (0xFFFFFEFF)	N

Beginning in MySQL Cluster NDB 6.4.0, this parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters", for more information.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, the effective value of this parameter was limited by the size of `SendBufferMemory`; beginning with these releases, the actual value for `OverloadLimit` (up to the stated maximum) is used instead.

- `ShmKey`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	0 - 4294967039 (0xFFFFFEFF)	N

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- `ShmSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	bytes	1M	64K - 4294967039 (0xFFFFFEFF)	N

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- `SendSignalId`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	boolean	false	true, false	N

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	boolean	true	true, false	N

This parameter is a boolean (`Y`/`N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- `SigNum`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	0 - 4294967039 (0xFFFFFEFF)	N

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of `SigNum` is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.

17.3.3.12 SCI Transport Connections in MySQL Cluster

`[sci]` sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using `--with-ndb-sci=/your/path/to/SCI`. The `path` should point to a directory that contains at a minimum `lib` and `include` directories containing SISCI libraries and header files. (See Section 17.3.4, "Using High-Speed Interconnects with MySQL Cluster" for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between `ndbd` processes. Note also that using SCI Transporters means that the `ndbd` processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by `ndbd` processes. There should be at least one CPU per `ndbd` process, with at least one CPU left in reserve to handle operating system activities.

- `NodeId1`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	numeric	[none]	...	N

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `NodeId2`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	numeric	[none]	...	N

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

* `Host1SciId0`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	0 - 4294967039 (0xFFFFFEFF)	N

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

* `Host1SciId1`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

* `Host2SciId0`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	[none]	0 - 4294967039 (0xFFFFFEFF)	N

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).

* `Host2SciId1`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	0	0 - 4294967039 (0xFFFFFEFF)	N

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

* `HostName1`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	[none]	...	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

* `HostName2`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	name or IP address	[none]	...	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `SharedBufferSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	10M	64K - 4294967039 (0xFFFFFEFF)	N

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- `SendLimit`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	unsigned	8K	128 - 32K	N

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- `SendSignalId`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	boolean	true	true, false	N

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

Effective Version	Type/Units	Default	Range/Values	Restart Type
MySQL 5.1.0	boolean	false	true, false	N

This parameter is a boolean value, and is disabled by default. When `Checksum` is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- `OverloadLimit`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 6.4.0	bytes	0	0 - 4294967039 (0xFFFFFEFF)	N

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 17.3.3.14, "Configuring MySQL Cluster Send Buffer Parameters", for more information.

17.3.3.13 Configuring MySQL Cluster Parameters for Local Checkpoints

The parameters discussed in Logging and Checkpointing and in Data Memory, Index Memory, and String Memory that are used to configure local checkpoints for a MySQL Cluster do not exist in isolation, but rather are very much interdepedent on each other. In this section, we illustrate how these parameters—including `DataMemory`, `IndexMemory`, `NoOfDiskPagesToDiskAfterRestartTUP`, `NoOfDiskPagesToDiskAfterRestartACC`, and `NoOfFragmentLogFiles`—relate to one another in a working Cluster.

> **Important**
>
> The parameters `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC` were deprecated in MySQL 5.1.6. From MySQL 5.1.6 through 5.1.11, disk writes during LCPs took place at the maximum speed possible. Beginning with MySQL 5.1.12, the speed and throughput for LCPs are controlled using the parameters `DiskSyncSize`, `DiskCheckpointSpeed`, and `DiskCheckpointSpeedInRestart`. See Section 17.3.3.6, "Defining MySQL Cluster Data Nodes".

In this example, we assume that our application performs the following numbers of types of operations per hour:

- 50000 selects

- 15000 inserts

- 15000 updates

- 15000 deletes

We also make the following assumptions about the data used in the application:

- We are working with a single table having 40 columns.

- Each column can hold up to 32 bytes of data.

- A typical `UPDATE` run by the application affects the values of 5 columns.

- No `NULL` values are inserted by the application.

A good starting point is to determine the amount of time that should elapse between local checkpoints (LCPs). It is worth noting that, in the event of a system restart, it takes 40-60 percent of this interval to execute the REDO log—for example, if the time between LCPs is 5 minutes (300 seconds), then it should take 2 to 3 minutes (120 to 180 seconds) for the REDO log to be read.

The maximum amount of data per node can be assumed to be the size of the `DataMemory` parameter. In this example, we assume that this is 2 GB. The `NoOfDiskPagesToDiskAfterRestartTUP` parameter represents the amount of data to be checkpointed per unit time—however, this parameter is actually expressed as the number of 8K memory pages to be checkpointed per 100 milliseconds. 2 GB per 300 seconds is approximately 6.8 MB per second, or 700 KB per 100 milliseconds, which works out to roughly 85 pages per 100 milliseconds.

Similarly, we can calculate `NoOfDiskPagesToDiskAfterRestartACC` in terms of the time for local checkpoints and the amount of memory required for indexes—that is, the `IndexMemory`. Assuming that we permit 512 MB for indexes, this works out to approximately 20 8-KB pages per 100 milliseconds for this parameter.

Next, we need to determine the number of REDO log files required—that is, fragment log files—the corresponding parameter being `NoOfFragmentLogFiles`. We need to make sure that there are sufficient

REDO log files for keeping records for at least 3 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, we need only allow for 2 local checkpoints). In a production setting, there are always uncertainties—for instance, we cannot be sure that disks always operate at top speed or with maximum throughput. For this reason, it is best to err on the side of caution, so we double our requirement and calculate a number of fragment log files which should be enough to keep records covering 6 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, a number of fragment log files accommodating 4 local checkpoints should be sufficient).

It is also important to remember that the disk also handles writes to the REDO log, so if you find that the amount of data being written to disk as determined by the values of `NoOfDiskPagesToDiskAfterRestartACC` and `NoOfDiskPagesToDiskAfterRestartTUP` is approaching the amount of disk bandwidth available, you may wish to increase the time between local checkpoints.

Given 5 minutes (300 seconds) per local checkpoint, this means that we need to support writing log records at maximum speed for 6 * 300 = 1800 seconds (*MySQL Cluster NDB 6.3.8 and later*: 4 * 300 = 1200 seconds). The size of a REDO log record is 72 bytes plus 4 bytes per updated column value plus the maximum size of the updated column, and there is one REDO log record for each table record updated in a transaction, on each node where the data reside. Using the numbers of operations set out previously in this section, we derive the following:

- 50000 select operations per hour yields 0 log records (and thus 0 bytes), since `SELECT` statements are not recorded in the REDO log.

- 15000 `DELETE` statements per hour is approximately 5 delete operations per second. (Since we wish to be conservative in our estimate, we round up here and in the following calculations.) No columns are updated by deletes, so these statements consume only 5 operations * 72 bytes per operation = 360 bytes per second.

- 15000 `UPDATE` statements per hour is roughly the same as 5 updates per second. Each update uses 72 bytes, plus 4 bytes per column * 5 columns updated, plus 32 bytes per column * 5 columns—this works out to 72 + 20 + 160 = 252 bytes per operation, and multiplying this by 5 operation per second yields 1260 bytes per second.

- 15000 `INSERT` statements per hour is equivalent to 5 insert operations per second. Each insert requires REDO log space of 72 bytes, plus 4 bytes per record * 40 columns, plus 32 bytes per column * 40 columns, which is 72 + 160 + 1280 = 1512 bytes per operation. This times 5 operations per second yields 7560 bytes per second.

So the total number of REDO log bytes being written per second is approximately 0 + 360 + 1260 + 7560 = 9180 bytes. Multiplied by 1800 seconds, this yields 16524000 bytes required for REDO logging, or approximately 15.75 MB. The unit used for `NoOfFragmentLogFiles` represents a set of 4 16-MB log files—that is, 64 MB. Thus, the minimum value (3) for this parameter is sufficient for the scenario envisioned in this example, since 3 times 64 = 192 MB, or about 12 times what is required; the default value of 8 (or 512 MB) is more than ample in this case.

17.3.3.14 Configuring MySQL Cluster Send Buffer Parameters

Formerly, the NDB kernel used a send buffer whose size was fixed at 2MB for every node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused, and could result in large amounts of resources being wasted when scaling up to many API nodes.

Beginning with MySQL Cluster NDB 7.0, this problem is solved by employing a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the

send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of MySQL Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

  To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

Transporter	Maximum Send Buffer Size (bytes)
TCP	`SendBufferMemory` (default = 2M)
SCI	`SendLimit` (default = 8K) plus 16K
SHM	20K

  This enables existing configurations to function in close to the same way as they did with MySQL Cluster NDB 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`Send Buffers overloaded in NDB kernel`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** In MySQL Cluster NDB 6.3 and earlier, this TCP configuration parameter represented the amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 7.0, this value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

- **ReservedSendBufferMemory.** This optional data node parameter, if set, gives an amount of memory (in bytes) that is reserved for connections between data nodes; this memory is not allocated to send buffers used for communications with management servers or API nodes. This provides a way to protect the cluster against misbehaving API nodes that use excess send memory and thus cause failures in communications internally in the NDB kernel. If set, its the minimum permitted value for this parameters is 256KB; the maximum is 4294967039.

17.3.4 Using High-Speed Interconnects with MySQL Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The MySQL Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in Section 17.3.3.9, "MySQL Cluster TCP/IP Connections".

- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See Section 17.3.3.10, "MySQL Cluster TCP/IP Connections Using Direct Connections", for details.

- *Shared memory (SHM).* For more information about SHM, see Section 17.3.3.11, "MySQL Cluster Shared-Memory Connections".

> **Note**
>
> SHM is considered experimental only, and is not officially supported.

- *Scalable Coherent Interface (SCI)*, as described in the next section of this chapter, Section 17.3.3.12, "SCI Transport Connections in MySQL Cluster".

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in "chunks" that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by Dolphin Interconnect Solutions.

17.3.4.1 Configuring MySQL Cluster to use SCI Sockets

It is possible employing Scalable Coherent Interface (SCI) technology to achieve a significant increase in connection speeds and throughput between MySQL Cluster data and SQL nodes. To use SCI, it is necessary to obtain and install Dolphin SCI network cards and to use the drivers and other software supplied by Dolphin. You can get information on obtaining these, from Dolphin Interconnect Solutions. SCI SuperSocket or SCI Transporter support is available for 32-bit and 64-bit Linux, Solaris, Windows, and other platforms. See the Dolphin documentation referenced later in this section for more detailed information regarding platforms supported for SCI.

> **Note**
>
> Prior to MySQL 5.1.20, there were issues with building MySQL Cluster with SCI support (see Bug #25470), but these have been resolved due to work contributed by Dolphin. SCI Sockets are now correctly supported for MySQL Cluster hosts running recent versions of Linux using the `-max` builds, and versions of MySQL Cluster with SCI Transporter support can be built using either of `compile-amd64-max-sci` or `compile-pentium64-max-sci`. Both of these build scripts can be found in the `BUILD` directory of the MySQL Cluster source trees; it should not be difficult to adapt them for other platforms. Generally, all that is necessary is to compile MySQL Cluster with SCI Transporter support is to configure the MySQL Cluster build using `--with-ndb-sci=/opt/DIS`.

Once you have acquired the required Dolphin hardware and software, you can obtain detailed information on how to adapt a MySQL Cluster configured for normal TCP/IP communication to use SCI from the from the Dolphin SCI online documentation.

17.3.4.2 MySQL Cluster Interconnects and Performance

The `ndbd` process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access.**   This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.

- **Unique key access.**   Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by `ndbd`. Such requests also benefit from batching.

- **Full table scan.**   When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the `ndbd` process, which then divides the table scan into a set of parallel scans on all cluster `ndbd` processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.

- **Range scan using ordered index.**   When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

With benchmarks developed internally by MySQL for testing simple and batched primary and unique key accesses, we have found that using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the `ndbd` processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between `ndbd` processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the `ndbd` process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the `ndbd` process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the `ndbd` process will benefit by 10−70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. However, we have tested MySQL Cluster so far only with SCI sockets. See Section 17.3.4.1, "Configuring MySQL Cluster to use SCI Sockets", for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

17.4 MySQL Cluster Programs

Using and managing a MySQL Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in a MySQL Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the MySQL Cluster data, management, and SQL node processes (`ndbd`, `ndbmtd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

For information about using `mysqld` as a MySQL Cluster process, see Section 17.5.4, "MySQL Server Usage for MySQL Cluster".

Other `NDB` utility, diagnostic, and example programs are included with the MySQL Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various MySQL Cluster programs.

17.4.1 `ndbd` — The MySQL Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the MySQL Cluster data node program `ndbd`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndbd`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.69 This table describes command-line options for the ndbd program

Format	Description	Added or Removed
`--initial`	Perform initial start of ndbd, including cleaning the file system. Consult the documentation before using this option	All MySQL 5.1 based releases
`--nostart`, `-n`	Don't start ndbd immediately; ndbd waits for command to start from ndb_mgmd	All MySQL 5.1 based releases
`--daemon`, `-d`	Start ndbd as daemon (default); override with --nodaemon	All MySQL 5.1 based releases
`--nodaemon`	Do not start ndbd as daemon; provided for testing purposes	All MySQL 5.1 based releases
`--foreground`	Run ndbd in foreground, provided for debugging purposes (implies --nodaemon)	All MySQL 5.1 based releases
`--nowait-nodes=list`	Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires --ndb-nodeid to be used.	ADDED: 5.1.9
`--initial-start`	Perform partial initial start (requires --nowait-nodes)	ADDED: 5.1.11
`--bind-address=name`	Local bind address	ADDED: 5.1.12
`--install[=name]`	Used to install the data node process as a Windows service.	ADDED: NDB 7.0.16, NDB 7.1.5

Format	Description	Added or Removed
	Does not apply on non-Windows platforms.	
`--remove[=name]`	Used to remove a data node process that was previously installed as a Windows service. Does not apply on non-Windows platforms.	ADDED: NDB 7.0.16, NDB 7.1.5
`--connect-retries=#`	Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries)	ADDED: NDB 7.0.36, NDB 7.1.25
`--connect-delay=#`	Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts	ADDED: NDB 7.0.36, NDB 7.1.25

> **Note**
>
> All of these options also apply to the multi-threaded version of this program (`ndbmtd`, available in MySQL Cluster NDB 7.0 and later) and you may substitute "`ndbmtd`" for "`ndbd`" wherever the latter occurs in this section.

- `--bind-address`

Introduced	5.1.12	
Command-Line Format	`--bind-address=name`	
Permitted Values	**Type**	`string`
	Default	

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

This option was added in MySQL 5.1.12.

- `--daemon`, `-d`

Command-Line Format	`--daemon`	
Permitted Values	**Type**	`boolean`
	Default	`TRUE`

Instructs `ndbd` or `ndbmtd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

- `--nodaemon`

Command-Line Format	`--nodaemon`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Prevents `ndbd` or `ndbmtd` from executing as a daemon process. This option overrides the `--daemon` option. This is useful for redirecting output to the screen when debugging the binary.

As of MySQL Cluster NDB 7.0.8, the default behavior for `ndbd` and `ndbmtd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect. (Bug #45588)

- `--foreground`

Command-Line Format	`--foreground`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Causes `ndbd` or `ndbmtd` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

- `--initial`

Command-Line Format	`--initial`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the MySQL Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.

- When restarting the node with a new version of `ndbd`.

- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

Important

This option does *not* affect either of the following types of files:

- Backup files that have already been created by the affected node

- MySQL Cluster Disk Data files (see Section 17.5.12, "MySQL Cluster Disk Data Tables").

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of

> data occurs automatically, and requires no user intervention in a MySQL Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

Introduced	5.1.11	
Command-Line Format	`--initial-start`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

Prior to MySQL 5.1.19, it was not possible to perform DDL operations involving Disk Data tables on a partially started cluster. (See Bug #24631.)

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

This option was added in MySQL 5.1.11.

> **Important**
>
> Do not confuse this option with the `--nowait-nodes` option added for `ndb_mgmd` in MySQL Cluster NDB 7.0.10, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

Introduced	5.1.9	
Command-Line Format	`--nowait-nodes=list`	
Permitted Values	**Type**	`string`
	Default	

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

This option was added in MySQL 5.1.9.

- `--nostart`, `-n`

Command-Line Format	`--nostart`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see Section 17.5.2, "Commands in the MySQL Cluster Management Client").

- `--install[=name]`

Introduced	5.1.47-ndb-7.1.5	
Command-Line Format	`--install[=name]`	
Platform Specific	Windows	
Permitted Values	**Type**	`string`
	Default	`ndbd`

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

- `--remove[=name]`

Introduced	5.1.47-ndb-7.1.5	
Command-Line Format	`--remove[=name]`	
Platform Specific	Windows	
Permitted Values	**Type**	`string`

	Default	ndbd

Causes an ndbd process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to ndbd.

The --remove option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

- --connect-retries=#

Introduced	5.1.66-ndb-7.1.25	
Command-Line Format	--connect-retries=#	
Permitted Values	Type	numeric
	Default	12
	Min Value	0
	Max Value	65535

Determines the number of times that the data node attempts to contact a management server when starting. Setting this option to -1 causes the data node to keep trying to make contact indefinitely. The default is 12 attempts. The time to wait between attempts is controlled by the --connect-delay option.

This option was added in MySQL Cluster NDB 7.0.36 and MySQL Cluster 7.1.25.

- --connect-delay=#

Introduced	5.1.66-ndb-7.1.25	
Command-Line Format	--connect-delay=#	
Permitted Values	Type	numeric
	Default	5
	Min Value	0
	Max Value	3600

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the --connect-retries option). The default is 5 attempts.

This option was added in MySQL Cluster NDB 7.0.36 and MySQL Cluster 7.1.25.

ndbd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file.

These log files are listed below. node_id is the node's unique identifier. Note that node_id represents the node's unique identifier. For example, ndb_2_error.log is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in ndbd Error Messages.

Important

The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

  It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.

- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.

- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See Section 17.3.3.3, "MySQL Cluster Connection Strings", for additional information about this issue. Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs", describes other command-line options which can be used with `ndbd`. For information about data node configuration parameters, see Section 17.3.3.6, "Defining MySQL Cluster Data Nodes".

When `ndbd` starts, it actually initiates two processes. The first of these is called the "angel process"; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.1 in a production setting. See Section 17.1.6, "Known Limitations of MySQL Cluster".

17.4.2 `ndbinfo_select_all` — Select From ndbinfo Tables

`ndbinfo_select_all` is a client program that selects all rows and columns from one or more tables in the `ndbinfo` database. It is included with the MySQL Cluster distribution beginning with MySQL Cluster NDB 7.1.17.

Not all `ndbinfo` tables can be accessed by this program. `ndbinfo_select_all` can access the `counters`, `diskpagebuffer`, `logbuffers`, `logspaces`, `nodes`, `resources`, `threadblocks`, `threadstat`, and `transporters` tables.

To select from one or more `ndbinfo` tables using `ndbinfo_select_all`, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1  [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       33554432        262144  0
6       0       0       0       33554432        262144  0
7       0       0       0       33554432        262144  0
8       0       0       0       33554432        262144  0
== logspaces ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       268435456       0       0
5       0       0       1       268435456       0       0
5       0       0       2       268435456       0       0
5       0       0       3       268435456       0       0
6       0       0       0       268435456       0       0
6       0       0       1       268435456       0       0
6       0       0       2       268435456       0       0
6       0       0       3       268435456       0       0
7       0       0       0       268435456       0       0
7       0       0       1       268435456       0       0
7       0       0       2       268435456       0       0
7       0       0       3       268435456       0       0
8       0       0       0       268435456       0       0
8       0       0       1       268435456       0       0
```

```
8        0        0        2       268435456       0       0
8        0        0        3       268435456       0       0
shell>
```

The following table includes options that are specific to `ndbinfo_select_all`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndbinfo_select_all`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.70 This table describes command-line options for the ndbinfo_select_all program

Format	Description	Added or Removed
`--delay=#`	Set the delay in seconds between loops. Default is 5.	All MySQL 5.1 based releases

`--loops=#,`
 	
`-l`
	Set the number of times to perform the select. Default is 1.	All MySQL 5.1 based releases

`--database=db_name,`
 	
`-d`
	Name of the database where the table located.	All MySQL 5.1 based releases

`--parallelism=#,`
 	
`-p`
	Set the degree of parallelism.	All MySQL 5.1 based releases

- `--delay=seconds`

Command-Line Format	`--delay=#`	
Permitted Values	**Type**	`numeric`
	Default	5
	Min Value	0
	Max Value	`MAX_INT`

This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

- `--loops=number`, `-l` *number*

Command-Line Format	`--loops=#`	
Permitted Values	**Type**	`numeric`
	Default	1
	Min Value	0
	Max Value	`MAX_INT`

This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

17.4.3 `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)

`ndbmtd` is a multi-threaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmtd` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmtd` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmtd` differs from `ndbd`, and you should consult Section 17.4.1, "ndbd — The MySQL Cluster Data Node Daemon", for additional information about running MySQL Cluster data nodes that apply to both the single-threaded and multi-threaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmtd`. For more information about these options and parameters, see Section 17.4.1, "ndbd — The MySQL Cluster Data Node Daemon", and Section 17.3.3.6, "Defining MySQL Cluster Data Nodes", respectively.

`ndbmtd` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmtd`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an apppriate value before restarting the node if you wish for `ndbmtd` to run in multi-threaded fashion.) Similarly, an `ndbmtd` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multi-threaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Prior to MySQL Cluster NDB 7.0.6, there were known issues when using `ndbmtd` with MySQL Cluster Disk Data tables. If you wish to use multi-threaded data nodes with disk-based `NDB` tables, you should ensure that you are running MySQL Cluster NDB 7.0.6 or later (see Bug #41915 and Bug #44915)

Using `ndbmtd` differs from using `ndbd` in two key respects:

1. Because `ndbmtd` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter. For more information about this parameter and its use, see Multi-Threading Configuration Parameters (ndbmtd).

2. Trace files are generated by critical errors in `ndbmtd` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmtd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmtd` generates trace files describing what happened just prior to the error' occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the MySQL Cluster Development and Support teams. One trace file is generated for each `ndbmtd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmtd` process running as a MySQL Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If the is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmtd`. See ndbd Error Messages, for a listing of these.

> **Note**
>
> It is possible to use `ndbd` and `ndbmtd` concurrently on different data nodes in the same MySQL Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

17.4.4 `ndb_mgmd` — The MySQL Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the MySQL Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_mgmd`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.71 This table describes command-line options for the ndb_mgmd program

Format	Description	Added or Removed
`--config-file=file`, `-f`	Specify the cluster configuration file; in NDB-6.4.0 and later, needs --reload or --initial to override configuration cache if present	All MySQL 5.1 based releases
`--configdir=directory`, `--config-dir=directory`	Specify the cluster management server's configuration cache directory	ADDED: NDB 6.4.0
`--bind-address=ip_address`	Local bind address	ADDED: NDB 6.2.5, NDB 6.3.2
`--print-full-config`, `-P`	Print full configuration and exit	All MySQL 5.1 based releases
`--daemon`, `-d`	Run ndb_mgmd in daemon mode (default)	All MySQL 5.1 based releases
`--nodaemon`	Do not run ndb_mgmd as a daemon	ADDED: NDB 7.0.8
`--interactive`	Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only)	All MySQL 5.1 based releases
`--log-name=name`	A name to use when writing messages applying to this node in the cluster log.	ADDED: NDB 7.0.8
`--no-nodeid-checks`	Do not provide any node id checks	All MySQL 5.1 based releases
`--mycnf`	Read cluster configuration data from the my.cnf file	All MySQL 5.1 based releases
`--reload`	Causes the management server to compare the configuration file with its configuration cache	ADDED: NDB 6.4.0

Format	Description	Added or Removed
`--initial`	Causes the management server reload its configuration data from the configuration file, bypassing the configuration cache	ADDED: NDB 6.4.0
`--nowait-nodes=list`	Do not wait for these management nodes when starting this management server. Also requires --ndb-nodeid to be used.	ADDED: NDB 7.0.10, NDB 7.1.0
`--config-cache[=TRUE|FALSE]`	Enable the management server configuration cache; TRUE by default.	ADDED: NDB 7.0.15, NDB 7.1.4
`--install[=name]`	Used to install the management server process as a Windows service. Does not apply on non-Windows platforms.	ADDED: NDB 7.0.16, NDB 7.1.5
`--remove[=name]`	Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms.	ADDED: NDB 7.0.16, NDB 7.1.5

- `--bind-address=host[:port]`

Introduced	5.1.22-ndb-6.3.2	
Command-Line Format	`--bind-address=ip_address`	
Permitted Values	**Type**	`string`
	Default	`[none]`

When specified, this option limits management server connections by management clients to clients at the specified host name or IP address (and possibly port, if this is also specified). In such cases, a management client attempting to connect to the management server from any other address fails with the error `Unable to setup port: host:port!`

If the `port` is not specified, the management client attempts to use port 1186.

This option was added in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- `--no-nodeid-checks`

Command-Line Format	`--no-nodeid-checks`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Do not perform any checks of node IDs.

- `--configdir=dir_name`

Introduced	5.1.30-ndb-6.4.0

Command-Line Format	`--configdir=directory`	
	`--config-dir=directory` (>= 5.1.37-ndb-7.0.8)	
Permitted Values	**Type**	`file name`
	Default	`$INSTALLDIR/mysql-cluster`

In MySQL Cluster NDB 7.0 and later, specifies the cluster management server's configuration cache directory. Starting with MySQL Cluster NDB 7.0.8, `--config-dir` is accepted as an alias for this option.

- `--config-cache`

Introduced	5.1.44-ndb-7.1.4	
Command-Line Format	`--config-cache[=TRUE│FALSE]`	
Permitted Values	**Type**	`boolean`
	Default	`TRUE`

This option, whose default value is `1` (or `TRUE`, or `ON`), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see Section 17.3.3, "MySQL Cluster Configuration Files"). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`

- `--config-cache=FALSE`

- `--config-cache=OFF`

- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

This option was added in MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4.

Beginning with MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, `ndb_mgmd` no longer checks for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--config-file=filename`, `-f filename`

Command-Line Format	`--config-file=file`	
Permitted Values	**Type**	`file name`
	Default	`./config.ini`
Permitted Values (>= 5.1.30-ndb-6.4.0)	**Type**	`file name`
	Default	`[none]`

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

Beginning with MySQL Cluster NDB 6.4.0, this option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See Section 17.3.3, "MySQL Cluster Configuration Files", for more information.

Formerly, using this option together with `--initial` caused removal of the configuration cache even if the file was not found. This issue was resolved in MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.27. (Bug #1299289)

- `--mycnf`

Command-Line Format	`--mycnf`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Read configuration data from the `my.cnf` file.

- `--daemon`, `-d`

Command-Line Format	`--daemon`	
Permitted Values	**Type**	`boolean`
	Default	`TRUE`

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--interactive`

Command-Line Format	`--interactive`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other MySQL Cluster nodes.

- `--initial`

Introduced	5.1.30-ndb-6.4.0	
Command-Line Format	`--initial`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Beginning with MySQL Cluster NDB 6.4.0, configuration data is cached internally rather than being read from the cluster global configuration file each time the management server is started (see Section 17.3.3, "MySQL Cluster Configuration Files"). Using this option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

In MySQL Cluster NDB 7.0.8 and later, when starting, the management server checks for another management server in the same MySQL Cluster and tries to use its configuration data. In other words, `ndb_mgmd` ignores `--initial` unless it is the only management server running. This behavior has implications when performing a rolling restart of a MySQL Cluster with multiple management nodes. See Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster", for more information.

Formerly, using this option together with the `--config-file` option caused removal of the configuration cache even if the file was not found. Starting with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.27, the cache is cleared in such cases only if the configuration file is actually found. (Bug #1299289)

This option was introduced in MySQL Cluster NDB 6.4.0.

- `--log-name=`*name*

Introduced	5.1.37-ndb-7.0.8	
Command-Line Format	`--log-name=name`	
Permitted Values	**Type**	`string`
	Default	`MgmtSrvr`

Provides a name to be used for this node in the cluster log.

This option was added in MySQL Cluster NDB 7.0.8.

- `--nodaemon`

Introduced	5.1.37-ndb-7.0.8
Command-Line Format	`--nodaemon`
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Instructs `ndb_mgmd` not to start as a daemon process.

As of MySQL Cluster NDB 7.0.8, the default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms. (Bug #45588)

- `--print-full-config`, `-P`

Command-Line Format	`--print-full-config`
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file` (`-f`) option.

- `--reload`

Introduced	5.1.30-ndb-6.4.0
Command-Line Format	`--reload`
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Beginning with MySQL Cluster NDB 6.4.0, configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 17.3.3, "MySQL Cluster Configuration Files"). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

In MySQL Cluster NDB 7.0.8 and later, when starting, the management server checks for another management server in the same MySQL Cluster and tries to use its configuration data. In other words, `ndb_mgmd` ignores `--reload` unless it is the only management server running. This behavior has implications when performing a rolling restart of a MySQL Cluster with multiple management nodes. See Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster", for more information.

This option was introduced in MySQL Cluster NDB 6.4.0.

- `--nowait-nodes`

Introduced	5.1.39-ndb-7.1.0	
Command-Line Format	`--nowait-nodes=list`	
Permitted Values	**Type**	`numeric`
	Default	
	Min Value	`1`
	Max Value	`255`

When starting a MySQL Cluster is configured with two management nodes and running MySQL Cluster NDB 7.0 and later, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 192.168.0.101

[ndbd]
NodeId = 2
HostName = 192.168.0.102

[ndbd]
NodeId = 3
HostName = 192.168.0.103

[ndbd]
NodeId = 4
HostName = 192.168.0.104

[ndb_mgmd]
NodeId = 10
HostName = 192.168.0.150

[ndb_mgmd]
NodeId = 11
HostName = 192.168.0.151

[api]
NodeId = 20
HostName = 192.168.0.200

[api]
NodeId = 21
HostName = 192.168.0.201
```

Assume that you wish to start this cluster using only the management server having node ID `10` and running on the host having the IP address 192.168.0.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware

failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 192.168.0.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 192.168.0.150,192.168.0.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as MySQL Cluster SQL nodes connected to this cluster. See Section 17.3.3.3, "MySQL Cluster Connection Strings", for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` (or `ndbmtd` in MySQL Cluster NDB 7.0 and later) to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same MySQL Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

> **Note**
>
> When you later start the "missing" management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

This option was introduced in MySQL Cluster NDB 7.0.10 and MySQL Cluster NDB 7.1.0.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 17.3.3.3, "MySQL Cluster Connection Strings", for information about using connection strings. Section 17.4.4, "`ndb_mgmd` — The MySQL Cluster Management Server Daemon", describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, *node_id* is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 17.3, "Configuration of MySQL Cluster NDB 6.1-7.1", discusses how to set up this file.

- `ndb_`*`node_id`*`_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 17.5, "Management of MySQL Cluster".

  By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_`*`node_id`*`_cluster.log.`*`seq_id`*, where *`seq_id`* is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

- `ndb_`*`node_id`*`_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.

- `ndb_`*`node_id`*`.pid` is the process ID file used when running the management server as a daemon.

- `--install[=`*`name`*`]`

Introduced	5.1.47-ndb-7.1.5
Command-Line Format	`--install[=name]`
Platform Specific	Windows
Permitted Values	**Type** `string`
	Default `ndb_mgmd`

  Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

  It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

  The `--install` option has no effect on non-Windows platforms.

  This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

- `--remove[=`*`name`*`]`

Introduced	5.1.47-ndb-7.1.5
Command-Line Format	`--remove[=name]`
Platform Specific	Windows
Permitted Values	**Type** `string`
	Default `ndb_mgmd`

  Causes an `ndb_mgmd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndb_mgmd`.

  The `--remove` option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

17.4.5 `ndb_mgm` — The MySQL Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following table includes options that are specific to the MySQL Cluster management client program `ndb_mgm`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_mgm`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.72 This table describes command-line options for the ndb_mgm program

Format	Description	Added or Removed
`--try-reconnect=#`, `-t`	Set the number of times to retry a connection before giving up; synonym for --connect-retries	All MySQL 5.1 based releases
`--execute=name`, `-e`	Execute command and exit	All MySQL 5.1 based releases

- `--execute=command`, `-e command`

Command-Line Format	`--execute=name`

This option can be used to send a command to the MySQL Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"

shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See Section 4.2.4, "Using Options on the Command Line".

> **Note**
>
> If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks.

> Either single or double quotation marks may be used. If the management client
> command contains no space characters, the quotation marks are optional.

- `--try-reconnect=`*`number`*

Command-Line Format	`--try-reconnect=#`	
Permitted Values	**Type**	`integer`
	Default	`3`
	Min Value	`0`
	Max Value	`4294967295`

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds
until it succeeds. By using this option, it is possible to limit the number of attempts to *`number`* before
giving up and reporting an error instead.

Additional information about using `ndb_mgm` can be found in Section 17.5.2, "Commands in the MySQL
Cluster Management Client".

17.4.6 `ndb_blob_tool` — Check and Repair BLOB and TEXT columns of MySQL Cluster Tables

This tool, which is available in MySQL Cluster NDB 7.0.4 and later, can be used to check for and remove
orphaned BLOB column parts from `NDB` tables, as well as to generate a file listing any orphaned parts. It is
sometimes useful in diagnosing and repairing corrupted or damaged `NDB` tables containing `BLOB` or `TEXT`
columns.

The basic syntax for `ndb_blob_tool` is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or
more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause
`ndb_blob_tool` to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a
dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking `ndb_blob_tool`. In addition, you can optionally
follow the table name with the (comma-separated) names of one or more `BLOB` or `TEXT` columns from that
table. If no columns are listed, the tool works on all of the table's `BLOB` and `TEXT` columns. If you need to
specify a database, use the `--database` (`-d`) option.

The `--verbose` option provides additional information in the output about the tool's progress.

The following table includes options that are specific to `ndb_blob_tool`. Additional descriptions follow
the table. For options common to most MySQL Cluster programs (including `ndb_blob_tool`), see
Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster
Programs".

Table 17.73 This table describes command-line options for the ndb_blob_tool program

Format	Description	Added or Removed
`--check-orphans`	Check for orphan blob parts	ADDED: NDB 7.0.4
`--database=db_name,`	Database to find the table in.	ADDED: NDB 7.0.4

Format	Description	Added or Removed
`-d`		
`--delete-orphans`	Delete orphan blob parts	ADDED: NDB 7.0.4
`--dump-file=file`	Write orphan keys to specified file	ADDED: NDB 7.0.4
`--verbose`,	Verbose output	ADDED: NDB 7.0.4
`-v`		

- `--check-orphans`

Introduced	5.1.32-ndb-7.0.4	
Command-Line Format	`--check-orphans`	
Permitted Values (>= 5.1.32-ndb-7.0.4)	**Type**	`boolean`
	Default	`FALSE`

Check for orphaned BLOB parts in MySQL Cluster tables.

- `--database=db_name`, `-d`

Introduced	5.1.32-ndb-7.0.4	
Command-Line Format	`--database=db_name`	
Permitted Values (>= 5.1.32-ndb-7.0.4)	**Type**	`string`
	Default	`[none]`

Specify the database to find the table in.

- `--delete-orphans`

Introduced	5.1.32-ndb-7.0.4	
Command-Line Format	`--delete-orphans`	
Permitted Values (>= 5.1.32-ndb-7.0.4)	**Type**	`boolean`
	Default	`FALSE`

Remove orphaned BLOB parts from MySQL Cluster tables.

- `--dump-file=file`

Introduced	5.1.32-ndb-7.0.4	
Command-Line Format	`--dump-file=file`	
Permitted Values (>= 5.1.32-ndb-7.0.4)	**Type**	`file name`
	Default	`[none]`

Writes a list of orphaned BLOB column parts to `file`. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- `--verbose`

Introduced	5.1.32-ndb-7.0.4
Command-Line Format	`--verbose`

Permitted Values (>= 5.1.32-ndb-7.0.4)	Type	`boolean`
	Default	`FALSE`

Provide extra information in the tool's output regarding its progress.

Example

First we create an `NDB` table in the `test` database, using the `CREATE TABLE` statement shown here:

```
USE test;

CREATE TABLE btest (
    c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    c1 TEXT,
    c2 BLOB
)   ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, `ndb_blob_tool` generates the following output:

```
shell> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected

NDBT_ProgramExit: 0 - OK
```

The tool reports that there are no `NDB` BLOB column parts associated with column `c1`, even though `c1` is a `TEXT` column. This is due to the fact that, in an `NDB` table, only the first 256 bytes of a `BLOB` or `TEXT` column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no `BLOB` column parts are created by `NDB` for this column. See Section 11.7, "Data Type Storage Requirements", for more information.

17.4.7 `ndb_config` — Extract MySQL Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: a MySQL Cluster management node, or its `config.ini` or `my.cnf` file. By default, the management node is the source for the configuration data; to override the default, execute ndb_config with the `--config-file` or `--mycnf` option. Beginning with MySQL Cluster NDB 7.0.27 and MySQL

Cluster NDB 7.1.16, it is also possible to use a data node as the source by specifying its node ID using `--config_from_node=node_id`.

Beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, `ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

Beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, you can filter the results by section (`DB`, `SYSTEM`, or `CONNECTIONS`) using one of the options `--nodes`, `--system`, or `--connections`.

The following table includes options that are specific to `ndb_config`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_config`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.74 This table describes command-line options for the ndb_config program

Format	Description	Added or Removed
`--nodes`	Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with --system or --connections.	All MySQL 5.1 based releases
`--connections`	Print connections information ([tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file) only. Cannot be used with --system or --nodes.	All MySQL 5.1 based releases

`--query=string,`
 	
`-q`
	One or more query options (attributes)	All MySQL 5.1 based releases

`--host=name`	Specify host	All MySQL 5.1 based releases
`--type=name`	Specify node type	All MySQL 5.1 based releases

`--nodeid,`
 	
`--id`
	Get configuration of node with this ID	All MySQL 5.1 based releases

`--fields=string,`
 	
`-f`
	Field separator	All MySQL 5.1 based releases

`--rows=string,`
 	
`-r`
	Row separator	All MySQL 5.1 based releases

`--config-file=file_name`	Set the path to config.ini file	All MySQL 5.1 based releases
`--mycnf`	Read configuration data from my.cnf file	All MySQL 5.1 based releases
`-c`	Short form for --ndb-connectstring	ADDED: 5.1.12
`--configinfo`	Dumps information about all NDB configuration parameters in text format with default, maximum,	ADDED: NDB 6.3.25, NDB 7.0.6

Format	Description	Added or Removed
	and minimum values. Use with --xml to obtain XML output.	
`--configinfo --xml`	Use --xml with --configinfo to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values.	ADDED: NDB 6.3.25, NDB 7.0.6
`--system`	Print SYSTEM section information only (see ndb_config --configinfo output). Cannot be used with --nodes or --connections.	ADDED: NDB 7.0.27, NDB 7.1.16
`--config_from_node=#`	Obtain configuration data from the node having this ID (must be a data node).	ADDED: NDB 7.0.27, NDB 7.1.16

- `--usage`, `--help`, or `-?`

Command-Line Format	`--help`
	`--usage`

Causes `ndb_config` to print a list of available options, and then exit.

- `--config_from_node=#`

Introduced	5.1.56-ndb-7.1.16	
Command-Line Format	`--config_from_node=#`	
Permitted Values	Type	`numeric`
	Default	`none`
	Min Value	`1`
	Max Value	`48`

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

`--config_from_node` was added in MySQL Cluster NDB 7.0.27 and MySQL NDB 7.1.16.

- `--version`, `-V`

Command-Line Format	`--version`

Causes `ndb_config` to print a version information string, and then exit.

- `--ndb-connectstring=`*`connection_string`*

Command-Line Format	`--ndb-connectstring=connectstring`
	`--connect-string=connectstring`

Permitted Values	Type	string
	Default	localhost:1186

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 17.3.3.3, "MySQL Cluster Connection Strings", and defaults to `localhost:1186`.

The use of `-c` as a short version for this option is supported for `ndb_config` beginning with MySQL 5.1.12.

- `--config-file=path-to-file`

Command-Line Format	--config-file=file_name	
Permitted Values	Type	file name
	Default	

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--mycnf`

Command-Line Format	--mycnf	
Permitted Values	Type	boolean
	Default	FALSE

Read configuration data from the `my.cnf` file.

- `--query=query-options`, `-q query-options`

Command-Line Format	--query=string	
Permitted Values	Type	string
	Default	

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `id` (node ID), type (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` returns the node ID, node type, `DataMemory`, and `IndexMemory` for each node.

> **Note**
>
> If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=hostname`

Command-Line Format	--host=name	
Permitted Values	Type	string
	Default	

Specifies the host name of the node for which configuration information is to be obtained.

> **Note**
>
> While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all MySQL Cluster configuration values relating to hosts, or verify that all MySQL Cluster hosts handle `localhost` in the same fashion.

- `--id=node_id`

  `--nodeid=node_id`

Command-Line Format	`--ndb-nodeid=#`	
Permitted Values	**Type**	`numeric`
	Default	`0`

Either of these options can be used to specify the node ID of the node for which configuration information is to be obtained. `--nodeid` is the preferred form.

- `--nodes`

Command-Line Format	`--nodes`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Tells `ndb_config` to print information relating only to parameters defined in an `[ndbd]` or `[ndbd default]` section of the cluster configuration file (see Section 17.3.3.6, "Defining MySQL Cluster Data Nodes"). Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, this option had no affect.

This option is mutually exclusive with `--connections` and `--system`; only one of these 3 options can be used.

- `--connections`

Command-Line Format	`--connections`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[sci]`, `[sci default]`, `[shm]`, or `[shm default]` sections of the cluster configuration file (see Section 17.3.3.9, "MySQL Cluster TCP/IP Connections", Section 17.3.3.12, "SCI Transport Connections in MySQL Cluster", and Section 17.3.3.11, "MySQL Cluster Shared-Memory Connections", for more information). This option existed prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, but had no affect before then.

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- `--system`

Introduced	5.1.56-ndb-7.1.16
Command-Line Format	`--system`
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Tells `ndb_config` to print `SYSTEM` information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with `****** SYSTEM ******`) in the output of `ndb_config --configinfo`. The `--system` option was introduced in MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

- `--type=node_type`

Command-Line Format	`--type=name`
Permitted Values	**Type**	`enumeration`
	Default	`[none]`
	Valid Values	`ndbd`
		`mysqld`
		`ndb_mgmd`

Filters results so that only configuration values applying to nodes of the specified `node_type` (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--fields=delimiter`, `-f delimiter`

Command-Line Format	`--fields=string`
Permitted Values	**Type**	`string`
	Default	

Specifies a `delimiter` string used to separate the fields in the result. The default is "`,`" (the comma character).

> **Note**
>
> If the `delimiter` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--rows=separator`, `-r separator`

Command-Line Format	`--rows=string`
Permitted Values	**Type**	`string`
	Default	

Specifies a `separator` string used to separate the rows in the result. The default is a space character.

> **Note**
>
> If the `separator` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--configinfo`

The `--configinfo` option, added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, causes `ndb_config` to dump a list of each MySQL Cluster configuration parameter supported by the MySQL Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage

- The section of the `config.ini` file where the parameter may be used

- The parameter's data type or unit of measurement

- Where applicable, the parameter's default, minimum, and maximum values

- MySQL Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo

****** SYSTEM ******

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

****** DB ******

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

…
```

- `--configinfo --xml`

Introduced	5.1.34-ndb-7.0.6	
Command-Line Format	`--configinfo --xml`	
Permitted Values	**Type**	`boolean`
	Default	`false`

You can obtain the output of `ndb_config --configinfo` as XML by adding the `--xml` option (like the `--configinfo` option, available beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6). A portion of the resulting output is shown in this example:

```
shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.1.77-ndb-7.1.37"
                 ndbversion="458758" ndbversionmajor="7" ndbversionminor="0"
                 ndbversionbuild="6">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
           mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
           type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
           type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="NDBD">
    <param name="MaxNoOfSubscriptions"
           comment="Max no of subscriptions (default 0 == MaxNoOfTables)"
           type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="MaxNoOfSubscribers"
           comment="Max no of subscribers (default 0 == 2 * MaxNoOfTables)"
           type="unsigned" default="0" min="0" max="4294967039"/>

    …

  </section>

  …

</configvariables>
```

Note

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, the XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition (also beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10), the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
       restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or "rolling" restart of the cluster), but the `restart` attribute is included only if

the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

> ⚠️ **Important**
>
> The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the MySQL Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running MySQL Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` or `--xml` is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. *However, this behavior is not guaranteed and is subject to change at any time.* In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the MySQL Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

Examples

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
8:mysqld
9:mysqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (`:`), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
192.168.0.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' : ' -r '\n'
1 : 192.168.0.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 192.168.0.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 192.168.0.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 192.168.0.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

17.4.8 `ndb_cpcd` — Automate Testing for NDB Development

This utility is found in the `libexec` directory. It is part of an internal automated test framework used in testing and debugging MySQL Cluster. Because it can control processes on remote systems, it is not advisable to use `ndb_cpcd` in a production cluster.

The source files for `ndb_cpcd` may be found in the directory `storage/ndb/src/cw/cpcd`, in the MySQL Cluster source tree.

Deprecated feature.   As of MySQL Cluster NDB 7.0, this program is deprecated and no longer actively maintained. It is subject to removal in a future MySQL Cluster version.

17.4.9 `ndb_delete_all` — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given `NDB` table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

Usage

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_delete_all`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.75 This table describes command-line options for the ndb_delete_all program

Format	Description	Added or Removed
`--database=dbname`, `-d`	Name of the database in which the table is found	All MySQL 5.1 based releases
`--transactional`, `-t`	Perform the delete in a single transaction (may run out of operations)	All MySQL 5.1 based releases
`--tupscan`	Run tup scan	All MySQL 5.1 based releases
`--diskscan`	Run disk scan	All MySQL 5.1 based releases

- `--transactional`, `-t`

  Use of this option causes the delete operation to be performed as a single transaction.

> **Warning**
>
> With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

17.4.10 ndb_desc — Describe NDB Tables

ndb_desc provides a detailed description of one or more NDB tables.

Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
```

(*MySQL Cluster NDB 7.0.36 and later; MySQL Cluster NDB 7.1.25 and later:*)

```
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with ndb_desc are listed later in this section.

Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
    ('','guppy', 35, 2), ('','tuna', 2500, 150000),
    ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
    ('','grouper', 900, 125000), ('','puffer', 250, 2500);
```

Output from ndb_desc:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: 9
K Value: 6

NDBT_ProgramExit: 0 - OK
```

Information about multiple tables can be obtained in a single invocation of ndb_desc by using their names, separated by spaces. All of the tables must be in the same database.

Beginning with MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25, it is possible to obtain additional information about a specific index using the --table (short form: -t) option introduced in these versions and supplying the name of the index as the first argument to ndb_desc, as shown here:

```
shell> ./ndb_desc uk -d test -t fish
-- uk --
Version: 3
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 3
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
FragmentCount: 4
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex

NDBT_ProgramExit: 0 - OK
```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see NDB Schema Object Versions.

The `Extent_space` and `Free extent_space` columns were added in MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8. They are applicable only to `NDB` tables having columns on disk; for tables having only in-memory columns, these columns always contain the value `0`.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_1.log'
    INITIAL_SIZE 16M
    UNDO_BUFFER_SIZE 2M
    ENGINE NDB;

ALTER LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_2.log'
    INITIAL_SIZE 12M
    ENGINE NDB;

CREATE TABLESPACE ts_1
    ADD DATAFILE 'data_1.dat'
    USE LOGFILE GROUP lg_1
    INITIAL_SIZE 32M
    ENGINE NDB;

ALTER TABLESPACE ts_1
    ADD DATAFILE 'data_2.dat'
    INITIAL_SIZE 48M
    ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see Section 17.5.12.1, "MySQL Cluster Disk Data Objects", as well as Section 13.1.14, "CREATE LOGFILE GROUP Syntax", and Section 13.1.18, "CREATE TABLESPACE Syntax".)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```
CREATE TABLE fish (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
    ('','guppy', 35, 2), ('','tuna', 2500, 150000),
    ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
    ('','grouper', 900, 125000), ('','puffer', 250, 2500);
```

When run against this version of the table, `ndb_desc` displays the following output:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 3
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 321
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex
-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory ...
0          2          2             32768             ...
1          4          4             32768             ...

... Frag varsized memory  Extent_space  Free extent_space
... 32768                 0             0
... 32768                 0             0

NDBT_ProgramExit: 0 - OK
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

The following table includes options that are specific to `ndb_desc`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_desc`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.76 This table describes command-line options for the ndb_desc program

Format	Description	Added or Removed
--blob-info, -b	Include partition information for BLOB tables in output. Requires that the -p option also be used	ADDED: NDB 6.3.32, NDB 7.0.13, NDB 7.1.2
--database=dbname, -d	Name of database containing table	All MySQL 5.1 based releases
--extra-node-info, -n	Include partition-to-data-node mappings in output. Requires that the -p option also be used	ADDED: NDB 6.2.19, NDB 6.3.33, NDB 7.0.14, NDB 7.1.2

Format	Description	Added or Removed
`--extra-partition-info`, `-p`	Display information about partitions	All MySQL 5.1 based releases
`--retries=#`, `-r`	Number of times to retry the connection (once per second)	All MySQL 5.1 based releases
`--table=tbl_name`, `-t`	Specify the table in which to find an index. When this option is used, -p and -n have no effect and are ignored.	ADDED: NDB 7.0.36, NDB 7.1.25
`--unqualified`, `-u`	Use unqualified table names	All MySQL 5.1 based releases

- `--blob-info`, `-b`

  Include information about subordinate `BLOB` and `TEXT` columns.

  Use of this option also requires the use of the `--extra-partition-info` (`-p`) option.

  This option was added in MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2.

- `--database=`*db_name*, `-d`

  Specify the database in which the table should be found.

- `--extra-node-info`, `-n`

  Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in MySQL Cluster.

  Use of this option also requires the use of the `--extra-partition-info` (`-p`) option.

  This option was added in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.2.

- `--extra-partition-info`, `-p`

  Print additional information about the table's partitions.

- `--retries=#`, `-r`

  Try to connect this many times before giving up. One connect attempt is made per second.

- `--table=`*tbl_name*, `-t`

  Specify the table in which to look for an index.

  This option was added in MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25.

- `--unqualified`, `-u`

  Use unqualified table names.

17.4.11 `ndb_drop_index` — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an `NDB` table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

Usage

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named *index* from the *table* in the *database*.

The following table includes options that are specific to `ndb_drop_index`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_drop_index`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.77 This table describes command-line options for the ndb_drop_index program

Format	Description	Added or Removed
`--database=dbname`, `-d`	Name of the database in which the table is found	All MySQL 5.1 based releases

> **Warning**
>
> *Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server.* If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *******
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.1.77-ndb-7.1.37

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+------------------+
| Tables_in_ctest1 |
+------------------+
| a                |
| bt1              |
| bt2              |
| dogs             |
| employees        |
| fish             |
+------------------+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
```

```
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see Section 17.4.12, "`ndb_drop_table` — Drop an NDB Table") to drop the table.

17.4.12 `ndb_drop_table` — Drop an NDB Table

`ndb_drop_table` drops the specified `NDB` table. (If you try to use this on a table created with a storage engine other than `NDB`, the attempt fails with the error `723: No such table exists`.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an `NDB` table.

Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to `ndb_drop_table`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_drop_table`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.78 This table describes command-line options for the ndb_drop_table program

Format	Description	Added or Removed
`--database=dbname`, `-d`	Name of the database in which the table is found	All MySQL 5.1 based releases

17.4.13 `ndb_error_reporter` — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster.*

The following table includes command options specific to the MySQL Cluster program `ndb_error_reporter`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_error_reporter`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

`ndb_error_reporter` did not support the `--help` option prior to MySQL Cluster NDB 6.3.52, MySQL Cluster NDB 7.0.40, and MySQL Cluster NDB 7.1.29 (Bug #11756666, Bug #48606). The `--connection-timeout --dry-scp`, and `--skip-nodegroup` options were also added in these releases (Bug #16602002).

Table 17.79 This table describes command-line options for the ndb_error_reporter program

Format	Description	Added or Removed
`--connection-timeout=timeout`	Number of seconds to wait when connecting to nodes before timing out.	ADDED: NDB 6.3.52, NDB 7.0.40, NDB 7.1.29
`--dry-scp`	Disable scp with remote hosts; used only for testing.	ADDED: NDB 6.3.52, NDB 7.0.40, NDB 7.1.29

Format	Description	Added or Removed
`--fs`	Include file system data in error report; can use a large amount of disk space	All MySQL 5.1 based releases
`--skip-nodegroup=nodegroup_id`	Skip all nodes in the node group having this ID.	ADDED: NDB 6.3.52, NDB 7.0.40, NDB 7.1.29

Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- `--connection-timeout=timeout`

Introduced	5.1.72-ndb-7.1.29	
Command-Line Format	`--connection-timeout=timeout`	
Permitted Values	**Type**	`integer`
	Default	0

Wait this many seconds when trying to connect to nodes before timing out.

- `--dry-scp`

Introduced	5.1.72-ndb-7.1.29	
Command-Line Format	`--dry-scp`	
Permitted Values	**Type**	`boolean`
	Default	`TRUE`

Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

- `--fs`

Command-Line Format	`--fs`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

- `--skip-nodegroup=nodegroup_id`

Introduced	5.1.72-ndb-7.1.29	
Command-Line Format	`--connection-timeout=timeout`	
Permitted Values	**Type**	`integer`
	Default	`0`

Skip all nodes belong to the node group having the supplied node group ID.

17.4.14 `ndb_index_stat` — NDB Index Statistics Utility

`ndb_index_stat` provides per-fragment statistical information about indexes on `NDB` tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

Usage

To obtain basic index statistics about a given `NDB` table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database` (`-d`) option:

```
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an `NDB` table named `mytable` in the `test` database:

```
shell> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
sampleVersion:3 loadTime:1399585986 sampleCount:1994 keyBytes:7976
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000

NDBT_ProgramExit: 0 - OK
```

`sampleVersion` is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes sampleVersion to be incremented.

`loadTime` shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

`sampleCount` is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).

`sampleCount` can be compared with the cardinality of `SHOW INDEX` or `INFORMATION_SCHEMA.STATISTICS`, although the latter two provide a view of the table as a whole, while `ndb_index_stat` provides a per-fragment average.

`keyBytes` is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so `keyBytes` can be calculated in this case as shown here:

```
    keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from `INFORMATION_SCHEMA.COLUMNS` (this requires a MySQL Server and a MySQL client application).

`totalBytes` is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of `ndb_index_stat`.

The `--verbose` option provides some additional output, as shown here:

```
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected

NDBT_ProgramExit: 0 - OK

shell>
```

Options

The following table includes options that are specific to the MySQL Cluster `ndb_index_stat` utility.
Additional descriptions are listed following the table. For options common to most MySQL Cluster
programs (including `ndb_index_stat`), see Section 17.4.26, "Options Common to MySQL Cluster
Programs — Options Common to MySQL Cluster Programs".

Table 17.80 This table describes command-line options for the ndb_index_stat program

Format	Description	Added or Removed
`--database=name`, `-d`	Name of the database containing the table.	All MySQL 5.1 based releases
`--delete`	Delete index statistics for the given table, stopping any auto-update previously configured.	All MySQL 5.1 based releases
`--update`	Update index statistics for the given table, restarting any auto-update previously configured.	All MySQL 5.1 based releases
`--dump`	Print the query cache.	All MySQL 5.1 based releases
`--query=#`	Perform a number of random range queries on first key attr (must be int unsigned).	All MySQL 5.1 based releases
`--sys-drop`	Drop any statistics tables and events in NDB kernel (all statistics are lost)	All MySQL 5.1 based releases
`--sys-create`	Create all statistics tables and events in NDB kernel, if none of them already exist	All MySQL 5.1 based releases
`--sys-create-if-not-exist`	Create any statistics tables and events in NDB kernel that do not already exist.	All MySQL 5.1 based releases
`--sys-create-if-not-valid`	Create any statistics tables or events that do not already exist in the NDB kernel. after dropping any that are invalid.	All MySQL 5.1 based releases

Format	Description	Added or Removed
`--sys-check`	Verify that NDB system index statistics and event tables exist.	All MySQL 5.1 based releases
`--sys-skip-tables`	Do not apply sys-* options to tables.	All MySQL 5.1 based releases
`--sys-skip-events`	Do not apply sys-* options to events.	All MySQL 5.1 based releases
`--verbose`, `-v`	Turn on verbose output	All MySQL 5.1 based releases
`--loops=#`	Set the number of times to perform a given command. Default is 0.	All MySQL 5.1 based releases

ndb_index_stat statistics options.   The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see ndb_index_stat system options).

- `--database=`*name*`, -d `*name*

Command-Line Format	`--database=name`	
Permitted Values	**Type**	`string`
	Default	`[none]`
	Min Value	
	Max Value	

The name of the database that contains the table being queried.

- `--delete`

Command-Line Format	`--delete`	
Permitted Values	**Type**	`boolean`
	Default	`false`
	Min Value	
	Max Value	

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- `--update`

Command-Line Format	`--update`	
Permitted Values	**Type**	`boolean`
	Default	`false`
	Min Value	

	Max Value	

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- `--dump`

Command-Line Format	`--dump`	
Permitted Values	**Type**	`boolean`
	Default	`false`
	Min Value	
	Max Value	

Dump the contents of the query cache.

- `--query=#`

Command-Line Format	`--query=#`	
Permitted Values	**Type**	`numeric`
	Default	`0`
	Min Value	`0`
	Max Value	`MAX_INT`

Perform random range queries on first key attribute (must be int unsigned).

ndb_index_stat system options. The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see ndb_index_stat statistics options).

- `--sys-drop`

Command-Line Format	`--sys-drop`	
Permitted Values	**Type**	`boolean`
	Default	`false`
	Min Value	
	Max Value	

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

- `--sys-create`

Command-Line Format	`--sys-create`	
Permitted Values	**Type**	`boolean`

Default	`false`
Min Value	
Max Value	

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- `sys-create-if-not-exist`

Command-Line Format	`--sys-create-if-not-exist`	
Permitted Values	**Type**	`boolean`
	Default	`false`
	Min Value	
	Max Value	

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- `--sys-create-if-not-valid`

Command-Line Format	`--sys-create-if-not-valid`	
Permitted Values	**Type**	`boolean`
	Default	`false`
	Min Value	
	Max Value	

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- `--sys-check`

Command-Line Format	`--sys-check`	
Permitted Values	**Type**	`boolean`
	Default	`false`
	Min Value	
	Max Value	

Verify that all required system statistics tables and events exist in the NDB kernel.

- `--sys-skip-tables`

Command-Line Format	`--sys-skip-tables`

Permitted Values	Type	boolean
	Default	false
	Min Value	
	Max Value	

Do not apply any `--sys-*` options to any statistics tables.

- `--sys-skip-events`

Command-Line Format	`--sys-skip-events`	
Permitted Values	Type	boolean
	Default	false
	Min Value	
	Max Value	

Do not apply any `--sys-*` options to any events.

- `--verbose`

Command-Line Format	`--verbose`	
Permitted Values	Type	boolean
	Default	false
	Min Value	
	Max Value	

Turn on verbose output.

- `--loops=#`

Command-Line Format	`--loops=#`	
Permitted Values	Type	numeric
	Default	0
	Min Value	0
	Max Value	MAX_INT

Repeat commands this number of times (for use in testing).

17.4.15 `ndb_print_backup_file` — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

Usage

```
ndb_print_backup_file file_name
```

file_name is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 17.5.3.1, "MySQL Cluster Backup Concepts".

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

17.4.16 `ndb_print_file` — Print NDB Disk Data File Contents

`ndb_print_file` obtains information from a MySQL Cluster Disk Data file.

Usage

```
ndb_print_file [-v] [-q] file_name+
```

file_name is the name of a MySQL Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_file` must be run on a MySQL Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

`ndb_print_file` supports the following options:

- `-v`: Make output verbose.

- `-q`: Suppress output (quiet mode).

- `--help`, `-h`, `-?`: Print help message.

  This option did not work correctly prior to MySQL Cluster NDB 7.1.33. (Bug #17069285)

For more information, see Section 17.5.12, "MySQL Cluster Disk Data Tables".

17.4.17 `ndb_print_schema_file` — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

Usage

```
ndb_print_schema_file file_name
```

file_name is the name of a cluster schema file. For more information about cluster schema files, see MySQL Cluster Data Node File System Directory Files.

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

17.4.18 `ndb_print_sys_file` — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from a MySQL Cluster system file.

Usage

```
ndb_print_sys_file file_name
```

file_name is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see MySQL Cluster Data Node File System Directory Files.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

17.4.19 `ndbd_redo_log_reader` — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndbd_redo_log_reader` is intended for use primarily by MySQL Cluster developers and Support personnel in debugging and diagnosing problems.

This utility was made available as part of default builds beginning with MySQL Cluster NDB 6.1.3. It remains under development, and its syntax and behavior are subject to change in future releases. For this reason, it should be considered experimental at this time.

The C++ source files for `ndbd_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the MySQL Cluster program `ndbd_redo_log_reader`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndbd_redo_log_reader`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.81 This table describes command-line options for the ndbd_redo_log_reader program

Format	Description	Added or Removed
`-noprint`	Do not print records	All MySQL 5.1 based releases
`-nocheck`	Do not check records for errors	All MySQL 5.1 based releases
`--help`	Print usage information	ADDED: NDB 6.3.53, NDB 7.0.41, NDB 7.1.30

Usage

```
ndbd_redo_log_reader file_name [options]
```

`file_name` is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the redo log files matches the pattern `ndb_#_fs/D#/LCP/#/T#F#.Data`. In each case, the `#` represents a number (not necessarily the same number). For more information, see MySQL Cluster Data Node File System Directory Files.

The name of the file to be read may be followed by one or more of the options listed here:

Command-Line Format	`-noprint`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

  `-noprint`: Do not print the contents of the log file.

Command-Line Format	`-nocheck`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

  `-nocheck`: Do not check the log file for errors.

Introduced	5.1.73-ndb-7.1.30
Command-Line Format	`--help`

  `--help`: Print usage information.

  Added in MySQL Cluster NDB 6.3.53, MySQL Cluster NDB 7.0.41, and MySQL Cluster NDB 7.1.30. (Bug #11749591, Bug #36805)

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndbd_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

17.4.20 `ndb_restore` — Restore a MySQL Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see Section 17.5.3.2, "Using The MySQL Cluster

Management Client to Create a Backup"). This is equal to the number of data nodes in the cluster at the time that the backup was created.

> **Note**
>
> Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 17.5.8, "MySQL Cluster Single User Mode", for more information.

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_restore`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_restore`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.82 This table describes command-line options for the ndb_restore program

Format	Description	Added or Removed
`--connect`, `-c`	Alias for --connectstring.	All MySQL 5.1 based releases
`--nodeid=#`, `-n`	Restore backup files to node with this ID	All MySQL 5.1 based releases
`--backupid=#`, `-b`	Restore from the backup with the given ID	All MySQL 5.1 based releases
`--restore_data`, `-r`	Restore table data and logs into NDB Cluster using the NDB API	All MySQL 5.1 based releases
`--restore_meta`, `-m`	Restore metadata to NDB Cluster using the NDB API	All MySQL 5.1 based releases
`--no-upgrade`, `-u`	Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes	ADDED: 5.1.19
`--promote-attributes`, `-A`	Allow attributes to be promoted when restoring data from backup	ADDED: NDB 6.3.8
`--preserve-trailing-spaces`, `-P`	Allow preservation of trailing spaces (including padding) when promoting fixed-width string types to variable-width types	ADDED: NDB 6.3.8
`--no-restore-disk-objects`, `-d`	Do not restore objects relating to Disk Data	ADDED: 5.1.6
`--restore_epoch`, `-e`	Restore epoch info into the status table. Convenient on a MySQL Cluster replication slave for starting replication. The row in mysql.ndb_apply_status with id 0 will be updated/inserted.	All MySQL 5.1 based releases

Format	Description	Added or Removed
`--skip-table-check`, `-s`	Skip table structure check during restoring of data	ADDED: 5.1.17
`--parallelism=#`, `-p`	Number of parallel transactions to use while restoring data	All MySQL 5.1 based releases
`--print`	Print metadata, data and log to stdout (equivalent to --print_meta --print_data --print_log)	All MySQL 5.1 based releases
`--print_meta`	Print metadata to stdout	All MySQL 5.1 based releases
`--print_data`	Print data to stdout	All MySQL 5.1 based releases
`--print_log`	Print to stdout	All MySQL 5.1 based releases
`--backup_path=dir_name`	Path to backup files directory	ADDED: 5.1.17, NDB 6.1.5
`--dont_ignore_systab_0`, `-f`	Do not ignore system table during restore. Experimental only; not for production use	All MySQL 5.1 based releases
`--ndb-nodegroup-map=map`, `-z`	Nodegroup map for NDBCLUSTER storage engine. Syntax: list of (source_nodegroup, destination_nodegroup)	All MySQL 5.1 based releases
`--fields-enclosed-by=char`	Fields are enclosed with the indicated character	ADDED: 5.1.18
`--fields-terminated-by=char`	Fields are terminated by the indicated character	ADDED: 5.1.18
`--fields-optionally-enclosed-by`	Fields are optionally enclosed with the indicated character	ADDED: 5.1.18
`--lines-terminated-by=char`	Lines are terminated by the indicated character	ADDED: 5.1.18
`--hex`	Print binary types in hexadecimal format	ADDED: 5.1.18
`--tab=dir_name`, `-T dir_name`	Creates a tab-separated .txt file for each table in the given path	ADDED: 5.1.18
`--append`	Append data to a tab-delimited file	ADDED: 5.1.18
`--progress-frequency=#`	Print status of restoration each given number of seconds	All MySQL 5.1 based releases
`--no-binlog`	If a mysqld is connected and using binary logging, do not log the restored data	ADDED: NDB 6.2.16, NDB 6.3.16
`--verbose=#`	Level of verbosity in output	All MySQL 5.1 based releases
`--include-databases=db-list`	List of one or more databases to restore (excludes those not named)	ADDED: NDB 6.3.22, NDB 6.4.3
`--exclude-databases=db-list`	List of one or more databases to exclude (includes those not named)	ADDED: NDB 6.3.22, NDB 6.4.3

Format	Description	Added or Removed
`--include-tables=table-list`	List of one or more tables to restore (excludes those in same database that are not named); each table reference must include the database name	ADDED: NDB 6.3.22, NDB 6.4.3
`--exclude-tables=table-list`	List of one or more tables to exclude (includes those in the same database that are not named); each table reference must include the database name	ADDED: NDB 6.3.22, NDB 6.4.3
`--exclude-missing-columns`	Causes columns from the backup version of a table that are missing from the version of the table in the database to be ignored.	ADDED: NDB 6.3.26, NDB 7.0.7
`--exclude-missing-tables`	Causes tables from the backup that are missing from the database to be ignored.	ADDED: NDB 7.1.33
`--disable-indexes`	Causes indexes from a backup to be ignored; may decrease time needed to restore data.	ADDED: NDB 6.3.31, NDB 7.0.11, NDB 7.1.2
`--rebuild-indexes`	Causes multi-threaded rebuilding of ordered indexes found in the backup. Number of threads used is determined by setting BuildIndexThreads parameter.	ADDED: NDB 6.3.31, NDB 7.0.11, NDB 7.1.2
`--skip-broken-objects`	Causes missing blob tables in the backup file to be ignored.	ADDED: NDB 6.3.40, NDB 7.0.21, NDB 7.1.10
`--skip-unknown-objects`	Causes schema objects not recognized by ndb_restore to be ignored when restoring a backup made from a newer MySQL Cluster version to an older version.	ADDED: NDB 6.3.34, NDB 7.0.15, NDB 7.1.4
`--rewrite-database=olddb,newdb`	Restores to a database with a different name than the original	ADDED: NDB 6.3.41, NDB 7.0.22, NDB 7.1.11
`--lossy-conversions`, `-L`	Allow lossy conversions of column values (type demotions or changes in sign) when restoring data from backup	ADDED: NDB 7.1.11
`--restore-privilege-tables`	Restore MySQL privilege tables that were previously moved to NDB.	ADDED: NDB 7.2.0
`--exclude-intermediate-sql-tables[=TRUE|FALSE]`	If TRUE (the default), do not restore any intermediate tables (having names prefixed with '#sql-') that were left over from copying ALTER TABLE operations.	ADDED: NDB 7.1.31

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
      [-m] -r --backup_path=/path/to/backup/files
```

Normally, when restoring from a MySQL Cluster backup, `ndb_restore` requires at a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup_path` options.

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server. (See Section 17.3.3.3, "MySQL Cluster Connection Strings", for information on connection strings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection "slot" to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see Section 17.3.3.7, "Defining SQL and Other API Nodes in a MySQL Cluster").

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

The `--nodeid` or `-n` is used to specify the node ID of the data node on which the backup should be restored.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--restore_meta` (`-m`) option. Restoring the metdata need be done only on a single data node; this is sufficient to restore it to the entire cluster. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore.)

It is possible to restore data without restoring table metadata. Prior to MySQL 5.1.17, `ndb_restore` did not perform any checks of table schemas; if a table was altered between the time the backup was taken and when `ndb_restore` was run, `ndb_restore` would still attempt to restore the data to the altered table.

Beginning with MySQL 5.1.17, the default behavior is for `ndb_restore` to fail with an error if table data do not match the table schema; this can be overridden using the `--skip-table-check` or `-s` option. Prior to MySQL 5.1.21, if this option is used, then `ndb_restore` attempts to fit data into the existing table schema, but the result of restoring a backup to a table schema that does not match the original is unspecified.

Beginning with MySQL Cluster NDB 6.3.35, MySQL Cluster NDB 7.0.16, and MySQL Cluster NDB 7.1.5, some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)

- Different `STORAGE` settings (`MEMORY`, `DISK`)

- Different default values

- Different distribution key settings

Beginning with MySQL Cluster NDB 6.3.8, `ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a "larger, similar" type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See Replication of Columns Having Different Data Types, for a table of type conversions currently supported by attribute promotion.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.

2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

Prior to MySQL Cluster NDB 7.0.40 and MySQL Cluster NDB 7.1.29, conversions between character data types and `TEXT` or `BLOB` were not handled correctly (Bug #17325051).

Prior to MySQL Cluster NDB 7.1.32, demotion of `TEXT` to `TINYTEXT` was not handled correctly (Bug #18875137).

When converting between character data types and `TEXT` or `BLOB`, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an `INT` column to `BIGINT` while promoting a `VARCHAR` column to `TEXT` in the same invocation of `ndb_restore`.

Converting between `TEXT` columns using different character sets is not supported. Beginning with MySQL Cluster NDB 7.1.32, it is expressly disallowed (Bug #18875137).

When performing conversions of character or binary types to `TEXT` or `BLOB` with `ndb_restore`, you may notice that it creates and uses one or more staging tables named `table_name$ST`*node_id*. These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

`--lossy-conversions`, `-L`

Introduced	5.1.51-ndb-7.1.11	
Command-Line Format	`--lossy-conversions`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

This option was added in MySQL Cluster NDB 7.1.11.

The `--preserve-trailing-spaces` option is also available beginning with MySQL Cluster NDB 6.3.8. This option (short form `-R`) causes trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR` or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

> **Note**
>
> Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

The `-b` option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See Section 17.5.3.2, "Using The MySQL Cluster Management Client to Create a Backup".)

> **Important**
>
> When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

`--restore_epoch` (short form: `-e`) adds (or restores) epoch information to the cluster replication status table. This is useful for starting replication on a MySQL Cluster replication slave. When this option is used, the row in the `mysql.ndb_apply_status` having `0` in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See Section 17.6.9, "MySQL Cluster Backups With MySQL Cluster Replication".)

`--restore_data`

This option causes `ndb_restore` to output `NDB` table data and logs.

`--restore_meta`

This option causes `ndb_restore` to print `NDB` table metadata. Generally, you need only use this option when restoring the first data node of a cluster; additional data nodes can obtain the metadata from the first one.

`--restore-privilege-tables`

`ndb_restore` does not by default restore distributed MySQL privilege tables (MySQL Cluster NDB 7.2.0 and later). This option causes `ndb_restore` to restore the privilege tables.

This works only if the privilege tables were converted to `NDB` before the backup was taken. For more information, see Section 17.5.14, "Distributed MySQL Privileges for MySQL Cluster".

`--backup_path`

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup_path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup_path=`.

> **Note**
>
> Previous to MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, the path to the backup directory was specified as shown here, with `backup_path=` being optional:
>
> ```
> [backup_path=]/path/to/backup/files
> ```
>
> Beginning with MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, this syntax changed to `--backup_path=/path/to/backup/files`, to conform more closely with options used by other MySQL programs; `--backupid` is required, and there is no short form for this option.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID `12`, created in a cluster with two database nodes having the node IDs `2` and `3`, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each database node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See Section 17.2.7, "Upgrading and Downgrading MySQL Cluster", for more information.

> **Important**
>
> It is not possible to restore a backup made from a newer version of MySQL Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer MySQL Cluster version to do so.
>
> For example, to restore a cluster backup taken from a cluster running MySQL Cluster NDB 7.1.8 to a cluster running MySQL Cluster NDB 7.0.16, you must use the `ndb_restore` that comes with the MySQL Cluster NDB 7.1.8 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

  `--no-upgrade`

Formerly, when using `ndb_restore` to restore a backup made from a MySQL 5.0 cluster to a 5.1 cluster, `VARCHAR` columns were not resized and were recreated using the 5.0 fixed format. Beginning with MySQL 5.1.19, `ndb_restore` recreates such `VARCHAR` columns using MySQL Cluster 5.1's variable-width format. Also beginning with MySQL 5.1.19, this behavior can be overridden using the `--no-upgrade` option (short form: `-u`) when running `ndb_restore`.

  `--print_data`

The `--print_data` option causes `ndb_restore` to direct its output to `stdout`.

`TEXT` and `BLOB` column values are always truncated to the first 256 bytes in the output; this cannot currently be overridden when using `--print_data`.

Beginning with MySQL 5.1.18, several additional options are available for use with the `--print_data` option in generating data dumps, either to `stdout`, or to a file. These are similar to some of the options used with `mysqldump`, and are shown in the following list:

- `--tab`, `-T`

Introduced	5.1.18	
Command-Line Format	`--tab=dir_name`	
Permitted Values	**Type**	`directory name`

This option causes `--print_data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--fields-enclosed-by=string`

Introduced	5.1.18	
Command-Line Format	`--fields-enclosed-by=char`	
Permitted Values	**Type**	`string`
	Default	

Each column values are enclosed by the string passed to this option (regardless of data type; see next item).

- `--fields-optionally-enclosed-by=string`

Introduced	5.1.18	
Command-Line Format	`--fields-optionally-enclosed-by`	
Permitted Values	**Type**	`string`
	Default	

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=string`

Introduced	5.1.18	
Command-Line Format	`--fields-terminated-by=char`	
Permitted Values	**Type**	`string`
	Default	`\t (tab)`

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- `--hex`

Introduced	5.1.18
Command-Line Format	`--hex`

If this option is used, all binary values are output in hexadecimal format.

- `--fields-terminated-by=string`

Introduced	5.1.18
Command-Line Format	`--fields-terminated-by=char`

Permitted Values	Type	`string`
	Default	`\t (tab)`

This option specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--append`

Introduced	5.1.18
Command-Line Format	`--append`

When used with the `--tab` and `--print_data` options, this causes the data to be appended to any existing files having the same names.

> **Note**
>
> If a table has no explicit primary key, then the output generated when using the `--print_data` option includes the table's hidden primary key.

`--print_meta`

This option causes `ndb_restore` to print all metadata to `stdout`.

`--print_log`

The `--print_log` option causes `ndb_restore` to output its log to `stdout`.

`--print`

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print_data`, `--print_meta`, and `--print_log` options together.

> **Note**
>
> Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to a MySQL Cluster.

`--dont_ignore_systab_0`

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the `NDB` system table that is present in the backup. `--dont_ignore_systab_0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

`--ndb-nodegroup-map`, `-z`

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form *source_node_group, target_node_group*.

`--no-binlog`

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs. Available beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.16.

`--no-restore-disk-objects`, `-d`

This option stops `ndb_restore` from restoring any MySQL Cluster Disk Data objects, such as tablespaces and log file groups; see Section 17.5.12, "MySQL Cluster Disk Data Tables", for more information about these. Added in MySQL 5.1.6.

`--parallelism=#`, `-p`

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

`--progress-frequency=N`

Print a status report each *N* seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

`--verbose=#`

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

Beginning with MySQL 5.1.18, it is possible to restore only selected databases, or selected tables from a single database, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

* All tables from one or more databases

* One or more tables from a single database

`--include-databases=db_name[,db_name][,...]`

Introduced	5.1.32-ndb-6.4.3	
Command-Line Format	`--include-databases=db-list`	
Permitted Values	**Type**	`string`
	Default	

`--include-tables=db_name.tbl_name[,db_name.tbl_name][,...]`

Introduced	5.1.32-ndb-6.4.3	
Command-Line Format	`--include-tables=table-list`	
Permitted Values	**Type**	`string`
	Default	

Beginning with MySQL Cluster NDB 6.3.22 and MySQL Cluster NDB 6.4.3, you can (and should) use instead the `--include-databases` option or the `--include-tables` option for restoring only specific databases or tables, respectively. `--include-databases` takes a comma-delimited list of databases to be restored. `--include-tables` takes a comma-delimited list of tables (in `database.table` format) to be restored.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from a MySQL Cluster backup:

Option Used	Result
`--include-databases=db1`	Only tables in database `db1` are restored; all tables in all other databases are ignored
`--include-databases=db1,db2` (or `--include-databases=db1 --include-databases=db2`)	Only tables in databases `db1` and `db2` are restored; all tables in all other databases are ignored
`--include-tables=db1.t1`	Only table `t1` in database `db1` is restored; no other tables in `db1` or in any other database are restored
`--include-tables=db1.t2,db2.t1` (or `--include-tables=db1.t2 --include-tables=db2.t1`)	Only the table `t2` in database `db1` and the table `t1` in database `db2` are restored; no other tables in `db1`, `db2`, or any other database are restored

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

> **Note**
>
> Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, multiple `--include-*` options were not handled correctly, and the result of the options shown in the previous example was that only the tables `db3.t1` and `db3.t2` were actually restored. (Bug #48907)

`--exclude-databases=`*db_name*`[,`*db_name*`][,...]`

Introduced	5.1.32-ndb-6.4.3	
Command-Line Format	`--exclude-databases=db-list`	
Permitted Values	**Type**	`string`
	Default	

`--exclude-tables=`*db_name.tbl_name*`[,`*db_name.tbl_name*`][,...]`

Introduced	5.1.32-ndb-6.4.3	
Command-Line Format	`--exclude-tables=table-list`	
Permitted Values	**Type**	`string`
	Default	

Beginning with MySQL Cluster NDB 6.3.22 and MySQL Cluster NDB 6.4.3, it is possible to prevent one or more databases or tables from being restored using the `ndb_restore` options `--exclude-databases` and `--exclude-tables`. `--exclude-databases` takes a comma-delimited list of one or

more databases which should not be restored. `--exclude-tables` takes a comma-delimited list of one or more tables (using `database.table` format) which should not be restored.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` usng `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from a MySQL Cluster backup:

Option Used	Result
`--exclude-databases=db1`	All tables in all databases except `db1` are restored; no tables in `db1` are restored
`--exclude-databases=db1,db2` (or `--exclude-databases=db1 --exclude-databases=db2`)	All tables in all databases except `db1` and `db2` are restored; no tables in `db1` or `db2` are restored
`--exclude-tables=db1.t1`	All tables except `t1` in database `db1` are restored; all other tables in `db1` are restored; all tables in all other databases are restored
`--exclude-tables=db1.t2,db2.t1` (or `--exclude-tables=db1.t2 --exclude-tables=db2.t1`)	All tables in database `db1` except for `t2` and all tables in database `db2` except for table `t1` are restored; no other tables in `db1` or `db2` are restored; all tables in all other databases are restored

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

Note

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, multiple `--exclude-*` options were not handled correctly, with the result that the options shown in the previous example caused ndb_restore to exclude only the tables `db3.t1` and `db3.t2`. (Bug #48907)

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.

- All `--include-*` and `--exclude-*` options are evaluated in the order passed to ndb_restore, from right to left.

- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table "wins".

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

> **Note**
>
> Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, it was not possible to use `--include-databases` or `--include-tables` together with `--exclude-databases` or `--exclude-tables`, as these combinations were evaluated inconsistently. (Bug #48907)

`--exclude-missing-columns`

Introduced	5.1.35-ndb-7.0.7
Command-Line Format	`--exclude-missing-columns`

Beginning with MySQL Cluster NDB 6.3.26 and MySQL Cluster NDB 7.0.7, it is also possible to restore only selected table columns using the `--exclude-missing-columns` option. When this option is used, `ndb_restore` ignores any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the options described in the previous paragraph to do so, then restore data to the remaining tables using a complementary set of these options.

`--exclude-missing-tables`

Introduced	5.1.73-ndb-7.1.33
Command-Line Format	`--exclude-missing-tables`

Beginning with MySQL Cluster NDB 7.1.33, it is also possible to restore only selected tables columns using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

`--disable-indexes`

Introduced	5.1.41-ndb-7.1.2
Command-Line Format	`--disable-indexes`

Beginning with MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.2, you can use this option with `ndb_restore` to disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multi-threaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

`--rebuild-indexes`

Introduced	5.1.41-ndb-7.1.2
Command-Line Format	`--rebuild-indexes`

Beginning with MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.2, you can use this option with `ndb_restore` to cause multi-threaded rebuilding of the ordered indexes while

restoring a native `NDB` backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwith can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `DiskCheckpointSpeed` to provide additional disk bandwidth to redo logging, or reducing the `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`DiskCheckpointSpeed`), in order to free space more quickly.

`--skip-broken-objects`

Introduced	5.1.51-ndb-7.1.10
Command-Line Format	`--skip-broken-objects`

This option causes `ndb_restore` to ignore corrupt tables while reading a native `NDB` backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

This option was added in MySQL Cluster NDB 6.3.40, MySQL Cluster NDB 7.0.21, and MySQL Cluster NDB 7.1.10.

`--skip-unknown-objects`

Introduced	5.1.44-ndb-7.1.4
Command-Line Format	`--skip-unknown-objects`

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native `NDB` backup. This can be used for restoring a backup made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

This option was added in MySQL Cluster NDB 6.3.34, MySQL Cluster NDB 7.0.15, and MySQL Cluster NDB 7.1.4.

`--rewrite-database=old_dbname,new_dbname`

Introduced	5.1.51-ndb-7.1.11	
Command-Line Format	`--rewrite-database=olddb,newdb`	
Permitted Values	**Type**	`string`
	Default	`none`

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it

contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

> **Important**
>
> When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

This option was added in MySQL Cluster NDB 6.3.41, MySQL Cluster NDB 7.0.22, and MySQL Cluster NDB 7.1.11.

• `--exclude-intermediate-sql-tables[=TRUE|FALSE]`

Introduced	5.1.73-ndb-7.1.31
Command-Line Format	`--exclude-intermediate-sql-tables[=TRUE|FALSE]`
Permitted Values	**Type** `boolean`
	Default `TRUE`

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from such operations. This option is `TRUE` by default.

The `--exclude-intermediate-sql-tables` option was introduced in MySQL Cluster NDB 7.1.31. (Bug #17882305)

Error reporting.
`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may able to recover from them. Beginning with MySQL 5.1.12, it reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

> **Important**
>
> After using `ndb_restore` to initialize a MySQL Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually. To cause

the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node
before running `START SLAVE`. This is a known issue in MySQL Cluster.

17.4.21 `ndb_select_all` — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an `NDB` table to `stdout`.

Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

The following table includes options that are specific to the MySQL Cluster native backup restoration
program `ndb_select_all`. Additional descriptions follow the table. For options common to most MySQL
Cluster programs (including `ndb_select_all`), see Section 17.4.26, "Options Common to MySQL
Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.83 This table describes command-line options for the ndb_select_all program

Format	Description	Added or Removed
`--database=dbname`, `-d`	Name of the database in which the table is found	All MySQL 5.1 based releases
`--parallelism=#`, `-p`	Degree of parallelism	All MySQL 5.1 based releases
`--lock=#`, `-l`	Lock type	All MySQL 5.1 based releases
`--order=index`, `-o`	Sort resultset according to index whose name is supplied	All MySQL 5.1 based releases
`--descending`, `-z`	Sort resultset in descending order (requires order flag)	All MySQL 5.1 based releases
`--header`, `-h`	Print header (set to 0|FALSE to disable headers in output)	All MySQL 5.1 based releases
`--useHexFormat`, `-x`	Output numbers in hexadecimal format	All MySQL 5.1 based releases
`--delimiter=char`, `-D`	Set a column delimiter	All MySQL 5.1 based releases
`--disk`	Print disk references (useful only for Disk Data tables having nonindexed columns)	All MySQL 5.1 based releases
`--rowid`	Print rowid	All MySQL 5.1 based releases
`--gci`	Include GCI in output	All MySQL 5.1 based releases
`--gci64`	Include GCI and row epoch in output	All MySQL 5.1 based releases
`--tupscan`,	Scan in tup order	All MySQL 5.1 based releases

Format	Description	Added or Removed

`-t`
 	
`--nodata`
	Do not print table column data	All MySQL 5.1 based releases

- `--database=`*dbname*, `-d` *dbname*

  Name of the database in which the table is found. The default value is `TEST_DB`.

- `parallelism=#`, `-p #`

  Specifies the degree of parallelism.

- `--lock=`*lock_type*, `-l` *lock_type*

  Employs a lock when reading the table. Possible values for *lock_type* are:

  - `0`: Read lock

  - `1`: Read lock with hold

  - `2`: Exclusive read lock

  There is no default value for this option.

- `--order=`*index_name*, `-o` *index_name*

  Orders the output according to the index named *index_name*.

  > **Note**
  >
  > This is the name of an index, not of a column; the index must have been explicitly named when created.

- `--descending`, `-z`

  Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--header=FALSE`

  Excludes column headers from the output.

- `--useHexFormat -x`

  Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--delimiter=`*character*, `-D` *character*

  Causes the *character* to be used as a column delimiter. Only table data columns are separated by this delimiter.

  The default delimiter is the tab character.

- `--disk`

  Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--rowid`

  Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--gci`

  Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See Section 17.1, "MySQL Cluster Overview", and Section 17.5.6.2, "MySQL Cluster Log Events", for more information about checkpoints.

- `--gci64`

  Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- `--tupscan`, `-t`

  Scan the table in the order of the tuples.

- `--nodata`

  Causes any table data to be omitted.

Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
| id | name      |
+----+-----------+
|  3 | shark     |
|  6 | puffer    |
|  2 | tuna      |
|  4 | manta ray |
|  5 | grouper   |
|  1 | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned

NDBT_ProgramExit: 0 - OK
```

All string values are enclosed by square brackets ("[...]") in the output of `ndb_select_all`. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
    id INT(11) NOT NULL AUTO_INCREMENT,
```

```
    name VARCHAR(25) NOT NULL,
    breed VARCHAR(50) NOT NULL,
    PRIMARY KEY pk (id),
    KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
    ('', 'Lassie', 'collie'),
    ('', 'Scooby-Doo', 'Great Dane'),
    ('', 'Rin-Tin-Tin', 'Alsatian'),
    ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional ndb_select_all options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI     id name            breed         DISK_REF
834461  2  [Scooby-Doo]    [Great Dane]  [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878  4  [Rosscoe]       [Mutt]        [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463  3  [Rin-Tin-Tin]   [Alsatian]    [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657  1  [Lassie]        [Collie]      [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned

NDBT_ProgramExit: 0 - OK
```

> **Note**
>
> In earlier MySQL Cluster NDB 7.0 and 7.1 releases, ndb_select_all did not print
> any output for NULL values as it did in MySQL Cluster NDB 6.3 and earlier release
> series. This issue was fixed in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB
> 7.1.11. (Bug #60045)

17.4.22 ndb_select_count — Print Row Counts for NDB Tables

ndb_select_count prints the number of rows in one or more NDB tables. With a single table, the result is
equivalent to that obtained by using the MySQL statement SELECT COUNT(*) FROM tbl_name.

Usage

```
ndb_select_count [-c connection_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

The following table includes options that are specific to the MySQL Cluster native backup restoration
program ndb_select_count. Additional descriptions follow the table. For options common to most
MySQL Cluster programs (including ndb_select_count), see Section 17.4.26, "Options Common to
MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.84 This table describes command-line options for the ndb_select_count program

Format	Description	Added or Removed
--database=dbname, -d	Name of the database in which the table is found	All MySQL 5.1 based releases
--parallelism=#, -p	Degree of parallelism	All MySQL 5.1 based releases
--lock=#,	Lock type	All MySQL 5.1 based releases

Format	Description	Added or Removed
`-l`		

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

17.4.23 `ndb_show_tables` — Display List of NDB Tables

`ndb_show_tables` displays a list of all `NDB` database objects in the cluster. By default, this includes not only both user-created tables and `NDB` system tables, but `NDB`-specific indexes, internal triggers, and MySQL Cluster Disk Data objects as well.

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_show_tables`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_show_tables`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.85 This table describes command-line options for the ndb_show_tables program

Format	Description	Added or Removed
`--database=string`, `-d`	Specifies the database in which the table is found	All MySQL 5.1 based releases
`--loops=#`, `-l`	Number of times to repeat output	All MySQL 5.1 based releases
`--type=#`, `-t`	Limit output to objects of this type	All MySQL 5.1 based releases
`--unqualified`, `-u`	Do not qualify table names	All MySQL 5.1 based releases
`--parsable`, `-p`	Return output suitable for MySQL LOAD DATA INFILE statement	All MySQL 5.1 based releases
`--show-temp-status`	Show table temporary flag	All MySQL 5.1 based releases

Usage

```
ndb_show_tables [-c connection_string]
```

- `--database`, `-d`

  Specifies the name of the database in which the tables are found.

- `--loops`, `-l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--parsable`, `-p`

Using this option causes the output to be in a format suitable for use with `LOAD DATA INFILE`.

- `--show-temp-status`

If specified, this causes temporary tables to be displayed.

- `--type`, `-t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- `1`: System table
- `2`: User-created table
- `3`: Unique hash index

Any other value causes all `NDB` database objects to be listed (the default).

- `--unqualified`, `-u`

If specified, this causes unqualified object names to be displayed.

> **Note**
>
> Only user-created MySQL Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using `NDB` API applications such as `ndb_select_all` (see Section 17.4.21, "`ndb_select_all` — Print Rows from an NDB Table").

17.4.24 `ndb_size.pl` — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the `NDBCLUSTER` storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for MySQL Cluster.

- A working installation of Perl.

- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)

- Previous to MySQL 5.1.18, `ndb_size.pl` also required the `HTML::Template` module and an associated template file `share/mysql/ndb_size.tmpl`. Beginning with MySQL 5.1.18, `ndb_size.tmpl` is no longer needed (or included).

- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

The following table includes options that are specific to the MySQL Cluster program `ndb_size.pl`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_size.pl`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.86 This table describes command-line options for the ndb_size.pl program

Format	Description	Added or Removed
`--database=dbname`	The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server)	All MySQL 5.1 based releases
`--hostname[:port]`	Specify host and optional port as host[:port]	All MySQL 5.1 based releases
`--socket=file_name`	Specify a socket to connect to	ADDED: NDB 6.2.5
`--user=string`	Specify a MySQL user name	All MySQL 5.1 based releases
`--password=string`	Specify a MySQL user password	All MySQL 5.1 based releases
`--format=string`	Set output format (text or HTML)	All MySQL 5.1 based releases
`--excludetables=tbl_list`	Skip any tables in a comma-separated list of tables	All MySQL 5.1 based releases
`--excludedbs=db_list`	Skip any databases in a comma-separated list of databases	All MySQL 5.1 based releases
`--savequeries=file`	Saves all queries to the database into the file specified	All MySQL 5.1 based releases
`--loadqueries=file`	Loads all queries from the file specified; does not connect to a database	All MySQL 5.1 based releases
`--real_table_name=table`	Designates a table to handle unique index size calculations	ADDED: NDB 6.2.5

Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
       [--user=user] [--password=password]  \
       [--help|-h] [--format={html|text}] \
       [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name (and possibly a port as well) can be specified using `--hostname`; the default is `localhost`. Beginning with MySQL Cluster NDB 6.3.49, MySQL Cluster NDB 7.0.32, and MySQL Cluster NDB 7.1.21, you can specify a port in addition to the host using *host*:*port* format for the value of `--hostname`. The default port number is 3306. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format`

option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
--------------------------------------------------
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1

test.t1
-------

DataMemory for Columns (* means varsized DataMemory):
          Column Name            Type  Varsized  Key  4.1  5.0   5.1

                                            --        --         --
         Total Index DM/Row                 16        16         16

IndexMemory for Indexes:
            Index Name       4.1       5.0       5.1
               PRIMARY        33        16        16
                              --        --        --
         Indexes IM/Row       33        16        16

Summary (for THIS table):
                              4.1       5.0       5.1
      Fixed Overhead DM/Row    12        12        16
            NULL Bytes/Row      4         4         4
            DataMemory/Row     96        96        48
                  (Includes overhead, bitmap and indexes)

  Varsize Overhead DM/Row        0         0         8
  Varsize NULL Bytes/Row         0         0         4
     Avg Varside DM/Row          0         0        16

              No. Rows           0         0         0

       Rows/32kb DM Page       340       340       680
Fixedsize DataMemory (KB)        0         0         0

Rows/32kb Varsize DM Page        0         0      2040
  Varsize DataMemory (KB)        0         0         0

       Rows/8kb IM Page        248       512       512
         IndexMemory (KB)        0         0         0

Parameter Minimum Requirements
------------------------------
* indicates greater than default

            Parameter     Default        4.1          5.0          5.1
       DataMemory (KB)      81920          0            0            0
     NoOfOrderedIndexes       128          1            1            1
            NoOfTables        128          1            1            1
        IndexMemory (KB)    18432          0            0            0
   NoOfUniqueHashIndexes       64          0            0            0
```

NoOfAttributes	1000	3	3	3
NoOfTriggers	768	5	5	5

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using can be saved to a file using `--savequeries`; a file containing such arrays to be read in during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.

- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.

- The `IndexMemory` and `DataMemory` required per table and table row.

> **Note**
>
> Prior to MySQL 5.1.23, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.7, `ndb_size.pl` was invoked as shown here:
>
> ```
> perl ndb_size.pl db_name hostname username password > file_name.html
> ```
>
> For more information about this change, see Bug #28683 and Bug #28253.

17.4.25 `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.

- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.

- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.

- `STARTING`: The node's `ndbd` process has started, but the node has not yet joined the cluster.

- `STARTED`: The node is operational, and has joined the cluster.

- `SHUTTING_DOWN`: The node is shutting down.

- `SINGLE USER MODE`: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_waiter`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_waiter`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.87 This table describes command-line options for the ndb_waiter program

Format	Description	Added or Removed
`--no-contact`, `-n`	Wait for cluster to reach NO CONTACT state	All MySQL 5.1 based releases
`--not-started`	Wait for cluster to reach NOT STARTED state	All MySQL 5.1 based releases
`--single-user`	Wait for cluster to enter single user mode	All MySQL 5.1 based releases
`--timeout=#`, `-t`	Wait this many seconds, then exit whether or not cluster has reached desired state; default is 2 minutes (120 seconds)	All MySQL 5.1 based releases
`--nowait-nodes=list`	List of nodes not to be waited for.	ADDED: NDB 6.2.1
`--wait-nodes=list`, `-w`	List of nodes to be waited for.	ADDED: NDB 6.3.34, NDB 7.0.15, NDB 7.1.4

Usage

```
ndb_waiter [-c connection_string]
```

Additional Options

- `--no-contact`, `-n`

  Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--not-started`

  Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--timeout=seconds`, `-t seconds`

  Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- `--single-user`

  The program waits for the cluster to enter single user mode.

- `--nowait-nodes=list`

  When this option is used, ndb_waiter does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --nowait-nodes=1,3,7-9
```

> **⚠ Important**
>
> Do *not* use this option together with the `--wait-nodes` option.

This option was added in MySQL Cluster NDB 6.2.1.

- `--wait-nodes=`*list*`, -w` *list*

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --wait-nodes=2,4-6,10
```

> **⚠ Important**
>
> Do *not* use this option together with the `--nowait-nodes` option.

This option was added in MySQL Cluster NDB 6.3.34, 7.0.15, and 7.1.4.

Sample Output.   Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by "`...`") are omitted.

```
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...
```

```
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

NDBT_ProgramExit: 0 - OK
```

> **Note**
>
> If no connection string is specified, then `ndb_waiter` tries to connect to a
> management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

17.4.26 Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs

All MySQL Cluster programs accept the options described in this section, with the following exceptions:

- `mysqld`

- `ndb_print_backup_file`

- `ndb_print_schema_file`

- `ndb_print_sys_file`

Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with `mysqld`. You can use the `--help` option with any MySQL Cluster program—with the exception of `ndb_print_backup_file`, `ndb_print_schema_file`, and `ndb_print_sys_file`—to view a list of the options which the program supports.

The options in the following table are common to all MySQL Cluster executables (except those noted previously in this section).

Table 17.88 This table describes command-line options common to all MySQL Cluster programs

Format	Description	Added or Removed
`--help`, `--usage`, `-?`	Display help message and exit	All MySQL 5.1 based releases

Format	Description	Added or Removed
`--character-sets-dir=dir_name`	Directory where character sets are installed	All MySQL 5.1 based releases
`--core-file`	Write core on errors (defaults to TRUE in debug builds)	All MySQL 5.1 based releases
`--debug=options`	Enable output from debug calls. Can be used only for versions compiled with debugging enabled	All MySQL 5.1 based releases

`--ndb-connectstring=connectstring`
 	
`--connect-string=connectstring`,
 	
`-c`
	Set connection string for connecting to ndb_mgmd. Syntax: [nodeid=<id>;] [host=]<hostname>[:<port>]. Overrides entries specified in NDB_CONNECTSTRING or my.cnf.	All MySQL 5.1 based releases

`--ndb-mgmd-host=host[:port]`	Set the host (and port, if desired) for connecting to management server	All MySQL 5.1 based releases
`--ndb-nodeid=#`	Set node id for this node	All MySQL 5.1 based releases
`--ndb-optimized-node-selection`	Select nodes for transactions in a more optimal way	All MySQL 5.1 based releases
`--ndb-shm`	Allow for optimization using shared memory connections where available (was EXPERIMENTAL, later REMOVED)	REMOVED: NDB 7.0.16, NDB 7.1.5
`--version`, `-V`	Output version information and exit	All MySQL 5.1 based releases

For options specific to individual MySQL Cluster programs, see Section 17.4, "MySQL Cluster Programs".

See MySQL Server Options for MySQL Cluster, for `mysqld` options relating to MySQL Cluster.

- `--help`, `--usage`, `-?`

Command-Line Format	`--help`
	`--usage`

Prints a short list with descriptions of the available command options.

- `--character-sets-dir=`*name*

Command-Line Format	`--character-sets-dir=dir_name`	
Permitted Values	**Type**	`directory name`
	Default	

Tells the program where to find character set information.

- `--ndb-connectstring=`*connection_string*, `--connect-string=`*connection_string*, `-c` *connection_string*

Command-Line Format	`--ndb-connectstring=connectstring`	
	`--connect-string=connectstring`	
Permitted Values	Type	`string`
	Default	`localhost:1186`

This option takes a MySQL Cluster connection string that specifies the management server for the application to connect to, as shown here:

```
shell> ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see Section 17.3.3.3, "MySQL Cluster Connection Strings".

- `--core-file`

Command-Line Format	`--core-file`	
Permitted Values	Type	`boolean`
	Default	`FALSE`

Write a core file if the program dies. The name and location of the core file are system-dependent. (For MySQL Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If MySQL Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- `--debug[=options]`

Command-Line Format	`--debug=options`	
Permitted Values	Type	`string`
	Default	`d:t:O,/tmp/ndb_restore.trace`

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--ndb-mgmd-host=host[:port]`

Command-Line Format	`--ndb-mgmd-host=host[:port]`	
Permitted Values	Type	`string`
	Default	`localhost:1186`

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

Command-Line Format	`--ndb-nodeid=#`	
Permitted Values	Type	`numeric`

	Default	0

Sets this node's MySQL Cluster node ID. *The range of permitted values depends on the node's type (data, management, or API) and the MySQL Cluster software version.* See Section 17.1.6.2, "Limits and Differences of MySQL Cluster from Standard MySQL Limits", for more information.

- `--ndb-optimized-node-selection`

Command-Line Format	`--ndb-optimized-node-selection`	
Permitted Values	**Type**	`boolean`
	Default	`TRUE`

Optimize selection of nodes for transactions. Enabled by default.

- `--version`, `-V`

Command-Line Format	`--version`

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster.

See Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster"), for more information.

- `--ndb-shm`

Removed	5.1.47-ndb-7.1.5	
Command-Line Format	`--ndb-shm`	
Permitted Values	**Type**	`boolean`
	Default	`FALSE`

In older versions of MySQL Cluster, this experimental option allowed the application to use shared memory for optimization when available. `--ndb-shm` was removed from all MySQL Cluster programs beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster 7.1.5.

17.5 Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in Section 17.3, "Configuration of MySQL Cluster NDB 6.1-7.1", and Section 17.4, "MySQL Cluster Programs".

The next few sections cover the management of a running MySQL Cluster.

For information about security issues relating to management and deployment of a MySQL Cluster, see Section 17.5.11, "MySQL Cluster Security Issues".

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.)

The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

In MySQL Cluster NDB 7.1.1 and later, detailed information about cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see Section 17.5.10, "The ndbinfo MySQL Cluster Information Database".

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by MySQL Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the `SESSION_STATUS` table or the `GLOBAL_STATUS` table (in the `INFORMATION_SCHEMA` database). By comparing the values of the status variables before and after the execution of an SQL statement that acts on `NDB` tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of MySQL Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex MySQL Cluster management tasks, such as starting, stopping, or restarting a MySQL Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to MySQL Cluster. See MySQL™ Cluster Manager 1.3.6 User Manual, for more information.

17.5.1 Summary of MySQL Cluster Start Phases

This section provides a simplified outline of the steps involved when MySQL Cluster data nodes are started. More complete information can be found in MySQL Cluster Start Phases, in the *NDB Internals Guide.*

These phases are the same as those reported in the output from the *node_id* `STATUS` command in the management client (see Section 17.5.2, "Commands in the MySQL Cluster Management Client"). In MySQL Cluster NDB 7.1.1 and later, these start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

Start types.   There are several different startup types and modes, as shown in the following list:

- **Initial start.**   The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

  > **Note**
  >
  > Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.**   The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node restart.**   This is the online restart of a cluster node while the cluster itself is running.

- **Initial node restart.**   This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

Setup and initialization (phase -1).   Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID

2. Fetch configuration data

3. Allocate ports to be used for inter-node communications

4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

Freeing unused node IDs.   Normally, in the event of a problem with the node, the node disconnects from the management server, the socket used for the connection is closed, and the reserved node ID is freed. However, if a node is disconnected abruptly—for example, due to a hardware failure in one of the cluster hosts, or because of network issues—the normal closing of the socket by the operating system may not take place. In this case, the node ID continues to be reserved and not released until a TCP timeout occurs 10 or so minutes later.

To take care of this problem, you can use `PURGE STALE SESSIONS`. Running this statement forces all reserved node IDs to be checked; any that are not being used by nodes actually connected to the cluster are then freed.

Beginning with MySQL 5.1.11, timeout handling of node ID assignments is implemented. This performs the ID usage checks automatically after approximately 20 seconds, so that `PURGE STALE SESSIONS` should no longer be necessary in a normal Cluster start.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.**   The `NDBFS` and `NDBCNTR` blocks start (see NDB Kernel Blocks). Data node file systems are cleared on those data nodes that were started with `--initial` option.

- **Phase 1.**   In this stage, all remaining `NDB` kernel blocks are started. MySQL Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

  > **Note**
  >
  > When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.**   The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.

- **Phase 3.**   The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.

- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

  For a system restart:

  - Read schema or schemas.

  - Read data from the local checkpoint.

  - Apply all redo information until the latest restorable global checkpoint has been reached.

  For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.

- **Phase 6.** In this phase, node groups are defined and set up.

- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as `Started`. It is now possible for API nodes (including SQL nodes) to connect to the cluster.

- **Phase 8.** If this is a system restart, all indexes are rebuilt (by `DBDIH`).

- **Phase 9.** The node internal startup variables are reset.

- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.

- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA* *handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

17.5.2 Commands in the MySQL Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 17.5.6, "Event Reports Generated in MySQL Cluster"; commands for creating backups and restoring from them are provided in Section 17.5.3, "Online Backup of MySQL Cluster".

Using ndb_mgm with MySQL Cluster Manager. MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for a MySQL Cluster that is under MySQL Cluster Manager control. it is recommended *not* to use the `ndb_mgm` command-line client that comes with the MySQL Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see MySQL Cluster Manager Process Commands.

The management client has the following basic commands. In the listing that follows, *node_id* denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`

  Displays information on all available commands.

- `CONNECT` *`connection-string`*

  Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- `SHOW`

  Displays information on the cluster's status. Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`.

  Beginning with MySQL Cluster NDB 6.2.8 and MySQL Cluster NDB 6.3.6, the output from this command indicates when the cluster is in single user mode (status `SINGLE USER MODE`).

  Prior to MySQL Cluster NDB 7.0.26 and MySQL Cluster NDB 7.1.5, in a cluster having multiple management nodes, this command displayed information only for data nodes that were actually connected to the current management server; in addition, management servers could not find each other until all nodes had been started. Beginning with these versions, such issues are fixed (see Bug #12352191), and management nodes can be additionally be reported with status `RESUME` or `CONNECTED`.

- *`node_id`* `START`

  Brings online the data node identified by *`node_id`* (or all data nodes).

  `ALL START` works on all data nodes only, and does not affect management nodes.

  > **Important**
  >
  > To use this command to bring a data node online, the data node must have been started using `--nostart` or `-n`.

- *`node_id`* `STOP [-a] [-f]`

  Stops the data or management node identified by *`node_id`*.

  > **Note**
  >
  > `ALL STOP` works to stop all data nodes only, and does not affect management nodes.

  A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

  The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

  Normally, `STOP` fails if the result would cause an incomplete cluster. The `-f` option, added in MySQL Cluster NDB 7.0.19 and MySQL Cluster NDB 7.1.8, forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

  > **Warning**
  >
  > Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete

> cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in `NDB`.

- `node_id RESTART [-n] [-i] [-a] [-f]`

  Restarts the data node identified by `node_id` (or all data nodes).

  Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

  > **Note**
  >
  > Backup files and Disk Data files are not removed when this option is used.

  Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

  Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

  Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option, added in MySQL Cluster NDB 7.0.19 and MySQL Cluster NDB 7.1.8, forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- `node_id STATUS`

  Displays status information for the data node identified by `node_id` (or for all data nodes).

  Beginning with MySQL Cluster NDB 6.2.8 and MySQL Cluster NDB 6.3.6, the output from this command indicates when the cluster is in single user mode.

- `node_id REPORT report-type`

  Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

  Currently, there are three accepted values for `report-type`:

  - `BackupStatus` provides a status report on a cluster backup in progress

  - `MemoryUsage` displays how much data memory and index memory is being used by each data node as shown in this example:

    ```
    ndb_mgm> ALL REPORT MEMORY

    Node 1: Data usage is 5%(177 32K pages of total 3200)
    Node 1: Index usage is 0%(108 8K pages of total 12832)
    Node 2: Data usage is 5%(177 32K pages of total 3200)
    Node 2: Index usage is 0%(108 8K pages of total 12832)
    ```

In MySQL Cluster NDB 7.1.1 and later, this information is also available from the `ndbinfo.memoryusage` table.

- `EventLog` reports events from the event log buffers of one or more data nodes.

`report-type` is case-insensitive and "fuzzy"; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

Prior to MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26, `ALL REPORT BackupStatus` did not work correctly with multi-threaded data nodes. (Bug #15908907)

The `REPORT` command was introduced in MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

- `ENTER SINGLE USER MODE node_id`

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is permitted to access the database.

Currently, it is not possible for data nodes to join a MySQL Cluster while it is running in single user mode. (Bug #20395)

- `EXIT SINGLE USER MODE`

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

> **Note**
>
> It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- `QUIT`, `EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- `CREATE NODEGROUP nodeid[, nodeid, ...]`

Creates a new MySQL Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to a MySQL Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each MySQL Cluster node group must have the same number of nodes). In other words, if the MySQL Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

This command was introduced in MySQL Cluster NDB 6.4.0. For more information, see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online".

- `DROP NODEGROUP` *`nodegroup_id`*

Drops the MySQL Cluster node group with the given *`nodegroup_id`*.

This command can be used to drop a node group from a MySQL Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3    @10.100.2.67  (5.1.77-ndb-7.1.37, no nodegroup)
```

Prior to MySQL Cluster NDB 7.0.4, the `SHOW` output was not updated correctly following `DROP NODEGROUP`. (Bug #43413)

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.

2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

   `TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

`DROP NODEGROUP` was introduced in MySQL Cluster NDB 6.4.0. For more information, see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online".

Additional commands.   A number of other commands available in the `ndb_mgm` client are described elsewhere, as shown in the following list:

- `START BACKUP` is used to perform an online backup in the `ndb_mgm` client; the `ABORT BACKUP` command is used to cancel a backup already in progress. For more information, see Section 17.5.3, "Online Backup of MySQL Cluster".

- The `CLUSTERLOG` command is used to perform various logging functions. See Section 17.5.6, "Event Reports Generated in MySQL Cluster", for more information and examples.

- For testing and diagnostics work, the client also supports a `DUMP` command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see MySQL Cluster Internals.

- In older versions of MySQL Cluster (prior to MySQL 5.1.11), it could sometimes be necessary to force the management server to check connections to the data nodes to ensure that dropped connections were not missed. This could be done using the `PURGE STALE SESSIONS` command. Newer versions now perform this check automatically, so that the command is no longer needed. See Section 17.5.1, "Summary of MySQL Cluster Start Phases", for more information.

17.5.3 Online Backup of MySQL Cluster

The next few sections describe how to prepare for and then to create a MySQL Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a "native" MySQL Cluster backup. (For information about the creation of backups with `mysqldump`, see Section 4.5.4, "`mysqldump` — A Database Backup Program".) Restoration of MySQL Cluster backups is done using the `ndb_restore` utility provided with the MySQL Cluster distribution; for information about `ndb_restore` and its use in restoring MySQL Cluster backups, see Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup".

17.5.3.1 MySQL Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables

- **Table records.** The data actually stored in the database tables at the time that the backup was made

- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_id.ctl`

  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

  A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

17.5.3.2 Using The MySQL Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 17.5.3.3, "Configuration for MySQL Cluster Backups".)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `Backup failed: file already exists`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, backup IDs greater than 2147483648 (2^{31}) were not supported correctly. (Bug #43042) Beginning with these versions, the maximum possible backup ID is 4294967296 (2^{32}).

> **Note**
>
> Prior to MySQL Cluster NDB 7.0.5, when starting a backup using `ndb_mgm -e "START BACKUP"`, the `backup_id` was required. (Bug #31754)

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

* If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

* With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

* `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

Beginning with MySQL Cluster NDB 6.4.0, a `snapshot_option` can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous MySQL Cluster releases.

> **Note**
>
> If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a *wait_option* and a *snapshot_option* are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (ndb_mgm), if it not running already.

2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

backup_id is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, *backup_id* is the unique identifier for this particular backup, and *node_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking ndb_mgm with the -e or --execute option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given *backup_id* are stored in a subdirectory named `BACKUP-`*backup_id* in the backup directory.

Cancelling backups.   To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.

2. Execute this command:

   ```
   ndb_mgm> ABORT BACKUP backup_id
   ```

   The number *backup_id* is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup `*backup_id*` started from node `*management_node_id*).

3. The management client acknowledges the abort request with `Abort of backup `*backup_id*` ordered`.

   > **Note**
   >
   > At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

   ```
   Node 1: Backup 3 started from 5 has been aborted.
     Error: 1321 - Backup aborted by user request: Permanent error: User defined error
   Node 3: Backup 3 started from 5 has been aborted.
     Error: 1323 - 1323: Permanent error: Internal error
   Node 2: Backup 3 started from 5 has been aborted.
     Error: 1323 - 1323: Permanent error: Internal error
   Node 4: Backup 3 started from 5 has been aborted.
     Error: 1323 - 1323: Permanent error: Internal error
   ```

   In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

   > **Note**
   >
   > There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

   The `Backup `*backup_id*` started from node `*management_node_id*` has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

> **Note**
>
> If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

17.5.3.3 Configuration for MySQL Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

  The amount of memory used to buffer data before it is written to disk.

- `BackupLogBufferSize`

  The amount of memory used to buffer log records before these are written to disk.

- `BackupMemory`

  The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- `BackupWriteSize`

  The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- `BackupMaxWriteSize`

  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in Backup Parameters.

17.5.3.4 MySQL Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

> **Important**
>
> If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

`NDB` does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is "hot", restoring a MySQL Cluster from backup is not a 100% "hot" process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

17.5.4 MySQL Server Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the `NDBCLUSTER` storage engine, as it is in the precompiled binaries available from

http://dev.mysql.com/downloads/. If you build MySQL from source, you must invoke `configure` with one of the options to enable `NDBCLUSTER` storage engine support:

- `--with-plugins=ndbcluster`

- `--with-plugins=max`

- `--with-plugins=max-no-innodb`

(`--with-ndbcluster` also works to enable `NDBCLUSTER` support, but is deprecated and so produces a `configure` warning as of MySQL 5.1.9.)

For information about other MySQL server options and variables relevant to MySQL Cluster in addition to those discussed in this section, see Section 17.3.3.8, "MySQL Server Options and Variables for MySQL Cluster".

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.

- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an `NDB`-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID

- The host name or IP address for the management server (MGM node)

- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 17.3.3.3, "MySQL Cluster Connection Strings", for more information on connection strings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
     Id: 1
   User: system user
   Host:
     db:
Command: Daemon
   Time: 1
  State: Waiting for event from ndbcluster
   Info: NULL
```

> **Important**
>
> To participate in a MySQL Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with `NDB` tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as `NDB` tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in a MySQL Cluster, you must restart the server *without* the `--ndbcluster` option.

17.5.5 Performing a Rolling Restart of a MySQL Cluster

This section discusses how to perform a *rolling restart* of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

Configuration change.
To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

MySQL Cluster software upgrade or downgrade. To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a "rolling upgrade" (or "rolling downgrade", when reverting to an older version of MySQL Cluster).

Change on node host. To make changes in the hardware or operating system on which one or more MySQL Cluster node processes are running.

System reset (cluster reset).
To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd`, or possibly `ndbmtd` in MySQL Cluster NDB 7.0 and later) with the `--initial` option, which forces the data node to clear its file system and to reload all MySQL Cluster data and metadata from the other data nodes.

- Create a backup using the `ndb_mgm` client `BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

  See Section 17.5.3, "Online Backup of MySQL Cluster", and Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup", for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA INFILE`.

Resource Recovery.
To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other MySQL Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them.

   (If there are multiple management servers and you are using MySQL Cluster NDB 7.0.8 or later, see Rolling restarts with multiple management servers (MySQL Cluster NDB 7.0.8 and later).)

2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

The specifics for implementing a given rolling upgrade depend upon the changes being made. A more detailed view of the process is presented here:

Figure 17.8 MySQL Cluster Rolling Restarts By Type

In the previous diagram, the **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. On Windows (MySQL Cluster NDB 7.1.3 and later), you can also use the system `NET START` and `NET STOP` commands or the Windows Service Manager to start and stop nodes which have been installed as Windows services (see Section 17.2.2.4, "Installing MySQL Cluster Processes as Windows Services").

Restart indicates that the process may be restarted using the `ndb_mgm` management client `RESTART` command (see Section 17.5.2, "Commands in the MySQL Cluster Management Client").

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10. When performing an upgrade or downgrade of the cluster software, you must upgrade or downgrade the management nodes first, then the data nodes, and finally the SQL nodes. Doing so in any other order may leave the cluster in an unusable state.

MySQL Cluster NDB 6.3.29 and later; MySQL Cluster NDB 7.0.10 and later. MySQL Cluster supports a more flexible order for upgrading the cluster nodes. When upgrading a cluster running MySQL Cluster NDB 6.3.29 or later, or a cluster that is running MySQL Cluster NDB 7.0.10 or later, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different MySQL Cluster releases is neither intended nor supported for constant, long-term use in a production setting.

- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.

- For MySQL Cluster NDB 6.3, the ability to upgrade API nodes in any order relative to upgrading management nodes and data nodes is supported only for MySQL Cluster NDB 6.3.29 and later; for MySQL Cluster NDB 7.0, it supported only for MySQL Cluster NDB 7.0.10 and later. This means that, if you are upgrading from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 release, the "old" `NDB` engine version must be 6.3.29 or later, and the "new" `NDB` engine version must be 7.0.10 or later.

- When upgrading the cluster from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 release: Once you have started upgrading the API nodes, you should not perform DDL operations until all management nodes and data nodes have been upgraded. DML operations should be unaffected, and can continue while the upgrade is in progress.

  However, it is possible to perform DDL from an "old" (NDB 6.3 version) API node as long as the master data node is also running the "old" version of MySQL Cluster. You should keep in mind that a data node restart could result in the master node running a "new" (NDB 7.0 version) binary while one or more data nodes are still using the "old" (NDB 6.3) version; in this situation, no DDL can be performed from *any* API node, because the master data node is no longer using an NDB 6.3 binary, but the cluster still contains nodes which are not yet using NDB 7.0. For this reason, we recommend that you avoid performing DDL at any time while the upgrade is in progress.

- Features specific to the "new" version must not be used until all management nodes and data nodes have been upgraded.

  This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of MySQL Cluster in general.)

See also Bug #48528 and Bug #49163.

Rolling restarts with multiple management servers (MySQL Cluster NDB 7.0.8 and later). A change in MySQL Cluster NDB 7.0.8 in the way in which management nodes obtain configuration data makes it necessary to alter the procedure previously outlined, when performing a rolling restart of a MySQL Cluster with multiple management nodes. (Previously, a management node checked only its own configuration cache, but in MySQL Cluster NDB 7.0.8 and later, `ndb_mgmd` also checks to see if any other

management node is running, and, if so, tries to use that node's configuration data.) To keep this from occurring, and to force `ndb_mgmd` to reread its configuration file, perform the following steps:

1. Stop all MySQL Cluster `ndb_mgmd` processes.

2. Update all `config.ini` files.

3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.

4. If you started the first `ndb_mgmd` with the `--initial` option, you must also start any remaining `ndb_mgmd` processes using `--initial`.

   Regardless of any other options used when starting the first `ndb_mgmd`, you should not start any remaining `ndb_mgmd` processes after the first one using `--reload`.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

See also Bug #45495 and Bug #46488.

MySQL Cluster NDB 7.0.24 and later; MySQL Cluster NDB 7.1.13 and later. When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See Section 17.5.10.13, "The ndbinfo nodes Table".

17.5.6 Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

  By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where `node_id` is the node ID of the management server) in the management server's `DataDir`.

  Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See Section 17.3.3.5, "Defining a MySQL Cluster Management Server", for more information about these parameters.

- *Node logs* are local to each node.

  Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.

- *Priority*: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates "most important" and 15 "least important."

- *Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Data usage is 2%(76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Data usage is 2%(58 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Data usage is 2%(74 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 4: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 1: Node 9: API 5.1.77-ndb-7.1.37
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 2: Node 9: API 5.1.77-ndb-7.1.37
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 3: Node 9: API 5.1.77-ndb-7.1.37
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 4: Node 9: API 5.1.77-ndb-7.1.37
2007-01-26 19:59:22 [MgmSrvr] ALERT    -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT    -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.

- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.

- The severity of the event.

- The ID of the node reporting the event.

- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

17.5.6.1 MySQL Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log. In the listing that follows, `node_id` denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CLUSTERLOG ON`

  Turns the cluster log on.

- `CLUSTERLOG OFF`

  Turns the cluster log off.

- `CLUSTERLOG INFO`

Provides information about cluster log settings.

- `node_id` `CLUSTERLOG` `category=threshold`

  Logs `category` events with priority less than or equal to `threshold` in the cluster log.

- `CLUSTERLOG FILTER` `severity_level`

  Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
`STARTUP`	**7**
`SHUTDOWN`	**7**
`STATISTICS`	**7**
`CHECKPOINT`	**7**
`NODERESTART`	**7**
`CONNECTION`	**7**
`ERROR`	**15**
`INFO`	**7**

The `STATISTICS` category can provide a great deal of useful data. See Section 17.5.6.3, "Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client", for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

Note

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

Severity Level Value	Severity	Description
1	`ALERT`	A condition that should be corrected immediately, such as a corrupted system database
2	`CRITICAL`	Critical conditions, such as device errors or insufficient resources
3	`ERROR`	Conditions that should be corrected, such as configuration errors
4	`WARNING`	Conditions that are not errors, but that might require special handling

Severity Level Value	Severity	Description
5	`INFO`	Informational messages
6	`DEBUG`	Debugging messages used for `NDBCLUSTER` development

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER`—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

> ⚠️ **Important**
>
> Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in a MySQL Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

17.5.6.2 MySQL Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean "Global Checkpoint" and "Local Checkpoint", respectively.

CONNECTION Events

These events are associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
`Connected`	8	`INFO`	Data nodes connected
`Disconnected`	8	`ALERT`	Data nodes disconnected
`CommunicationClosed`	8	`INFO`	SQL node or data node connection closed
`CommunicationOpened`	8	`INFO`	SQL node or data node connection open
`ConnectedApiVersion`	8	`INFO`	Connection using API version

CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Event	Priority	Severity Level	Description
`GlobalCheckpointStarted`	9	`INFO`	Start of GCP: REDO log is written to disk
`GlobalCheckpointCompleted`	10	`INFO`	GCP finished

Event	Priority	Severity Level	Description
LocalCheckpointStarted	7	INFO	Start of LCP: data written to disk
LocalCheckpointCompleted	7	INFO	LCP completed normally
LCPStoppedInCalcKeepGci	0	ALERT	LCP stopped
LCPFragmentCompleted	11	INFO	LCP on a fragment has been completed
UndoLogBlocked	7	INFO	UNDO logging blocked; buffer near overflow
RedoStatus	7	INFO	Redo status

STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
NDBStartStarted	1	INFO	Data node start phases initiated (all nodes starting)
NDBStartCompleted	1	INFO	Start phases completed, all data nodes
STTORRYRecieved	15	INFO	Blocks received after completion of restart
StartPhaseCompleted	4	INFO	Data node start phase X completed
CM_REGCONF	3	INFO	Node has been successfully included into the cluster; shows the node, managing node, and dynamic ID
CM_REGREF	8	INFO	Node has been refused for inclusion in the cluster; cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
FIND_NEIGHBOURS	8	INFO	Shows neighboring data nodes
NDBStopStarted	1	INFO	Data node shutdown initiated
NDBStopCompleted	1	INFO	Data node shutdown complete
NDBStopForced	1	ALERT	Forced shutdown of data node
NDBStopAborted	1	INFO	Unable to shut down data node normally
StartREDOLog	4	INFO	New redo log started; GCI keep X, newest restorable GCI Y
StartLog	10	INFO	New log started; log part X, start MB Y, stop MB Z
UNDORecordsExecuted	15	INFO	Undo records executed
StartReport	4	INFO	Report started
LogFileInitStatus	7	INFO	Log file initialization status
LogFileInitCompStatus	7	INFO	Log file completion status
StartReadLCP	10	INFO	Start read for local checkpoint
ReadLCPComplete	10	INFO	Read for local checkpoint completed

Event	Priority	Severity Level	Description
RunRedo	8	INFO	Running the redo log
RebuildIndex	10	INFO	Rebuilding indexes

NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
NR_CopyDict	7	INFO	Completed copying of dictionary information
NR_CopyDistr	7	INFO	Completed copying distribution information
NR_CopyFragsStarted	7	INFO	Starting to copy fragments
NR_CopyFragDone	10	INFO	Completed copying a fragment
NR_CopyFragsCompleted	7	INFO	Completed copying all fragments
NodeFailCompleted	8	ALERT	Node failure phase completed
NODE_FAILREP	8	ALERT	Reports that a node has failed
ArbitState	6	INFO	Report whether an arbitrator is found or not; there are seven different possible outcomes when seeking an arbitrator, listed here: • Management server restarts arbitration thread [state=X] • Prepare arbitrator node X [ticket=Y] • Receive arbitrator node X [ticket=Y] • Started arbitrator node X [ticket=Y] • Lost arbitrator node X - process failure [state=Y] • Lost arbitrator node X - process exit [state=Y] • Lost arbitrator node X <error msg> [state=Y]
ArbitResult	2	ALERT	Report arbitrator results; there are eight different possible results for arbitration attempts, listed here: • Arbitration check failed: less than 1/2 nodes left • Arbitration check succeeded: node group majority • Arbitration check failed: missing node group • Network partitioning: arbitration required

Event	Priority	Severity Level	Description
			• Arbitration succeeded: affirmative response from node X • Arbitration failed: negative response from node X • Network partitioning: no arbitrator available • Network partitioning: no arbitrator configured
GCP_TakeoverStarted	7	INFO	GCP takeover started
GCP_TakeoverCompleted	7	INFO	GCP takeover complete
LCP_TakeoverStarted	7	INFO	LCP takeover started
LCP_TakeoverCompleted	7	INFO	LCP takeover complete (state = X)
ConnectCheckStarted	6	INFO	Connection check started
ConnectCheckCompleted	6	INFO	Connection check completed
NodeFailRejected	6	ALERT	Node failure phase failed

STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
TransReportCounters	8	INFO	Report transaction statistics, including numbers of transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
OperationReportCounters	8	INFO	Number of operations
TableCreated	7	INFO	Report number of tables created
JobStatistic	9	INFO	Mean internal job scheduling statistics
ThreadConfigLoop	9	INFO	Number of thread configuration loops
SendBytesStatistic	9	INFO	Mean number of bytes sent to node X
ReceiveBytesStatistic	9	INFO	Mean number of bytes received from node X
MemoryUsage	5	INFO	Data and index memory usage (80%, 90%, and 100%)
MTSignalStatistics	9	INFO	Multi-threaded signals

SCHEMA Events

These events relate to MySQL Cluster schema operations.

Event	Priority	Severity	Description
CreateSchemaObject	8	INFO	Schema objected created
AlterSchemaObject	8	INFO	Schema object updated

Event	Priority	Severity	Description
`DropSchemaObject`	8	`INFO`	Schema object dropped

ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
`TransporterError`	2	`ERROR`	Transporter error
`TransporterWarning`	8	`WARNING`	Transporter warning
`MissedHeartbeat`	8	`WARNING`	Node X missed heartbeat number Y
`DeadDueToHeartbeat`	8	`ALERT`	Node X declared "dead" due to missed heartbeat
`WarningEvent`	2	`WARNING`	General warning event
`SubscriptionStatus`	4	`WARNING`	Change in subscription status

INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
`SentHeartbeat`	12	`INFO`	Sent heartbeat
`CreateLogBytes`	11	`INFO`	Create log: Log part, log file, size in MB
`InfoEvent`	2	`INFO`	General informational event
`EventBufferStatus`	7	`INFO`	Event buffer status

> **Note**
>
> `SentHeartbeat` events are available only if MySQL Cluster was compiled with `VM_TRACE` enabled.

SINGLEUSER Events

These events are associated with entering and exiting single user mode.

Event	Priority	Severity	Description
`SingleUser`	7	`INFO`	Entering or exiting single user mode

BACKUP Events

These events provide information about backups being created or restored.

Event	Priority	Severity	Description
`BackupStarted`	7	`INFO`	Backup started
`BackupStatus`	7	`INFO`	Backup status
`BackupCompleted`	7	`INFO`	Backup completed
`BackupFailedToStart`	7	`ALERT`	Backup failed to start
`BackupAborted`	7	`ALERT`	Backup aborted by user

Event	Priority	Severity	Description
`RestoreStarted`	7	`INFO`	Started restoring from backup
`RestoreMetaData`	7	`INFO`	Restoring metadata
`RestoreData`	7	`INFO`	Restoring data
`RestoreLog`	7	`INFO`	Restoring log files
`RestoreCompleted`	7	`INFO`	Completed restoring from backup
`SavedEvent`	7	`INFO`	Event saved

17.5.6.3 Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client

The `NDB` management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

Transaction coordinator statistics.   Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion

- By communication proximity

- (*Beginning with MySQL Cluster NDB 6.3.4*:) By supplying a data placement hint when the transaction is started

> **Note**
>
> You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.**   This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

> **Note**
>
> Transactions do not migrate between TCs.

- **Commit count.**   This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.

- **Read count.**   This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.

- **Simple read count.**   This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval. This is a subset of `Read count`. Prior to

MySQL CLuster NDB 7.0, the value of `Simple read count` was incremented at a different point in time from `Read count`, which could cause it to lag behind `Read count` slightly, so that it was possible that `Simple read count` was not equal to `Read count` for some reporting interval, even if all reads made during that time were in fact simple reads. In MySQL Cluster NDB 7.0 and later, `NDB` uses a single signal (`TCKEYREQ`) containing all information necessary to forward the request, so these counts should no longer appear to be misaligned in such cases.

- **Write count.**   This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

> **Note**
>
> A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.**   This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

  Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.

- **Concurrent Operations.**   This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

  The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is `(2 * MaxNoOfConcurrentOperations) + 16 + MaxNoOfConcurrentTransactions`. (For more information about these configuration parameters, see the *Transaction Parameters* section of Section 17.3.3.6, "Defining MySQL Cluster Data Nodes".)

- **Abort count.**   This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, `Abort count` can sometimes be greater than `Trans count`.

- **Scans.**   This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).

- **Range scans.**   This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

Local query handler statistics (Operations).   There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

> **Note**
>
> A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

Process scheduler statistics.   In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of a MySQL Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.

2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.

3. Execute (in a loop) any messages in the job buffer.

4. Send any distributed messages that were generated by executing the messages in the job buffer.

5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.**   This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.

- **Mean send size and Mean receive size.**   These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

> **Note**
>
> Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the MySQL Cluster.

For more information about MySQL Cluster management client commands relating to logging and reporting, see Section 17.5.6.1, "MySQL Cluster Logging Management Commands".

17.5.7 MySQL Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on `NDB` transporter errors.

17.5.7.1 MySQL Cluster: Messages in the Cluster Log

The following table lists the most common `NDB` cluster log messages. For information about the cluster log, log events, and event types, see Section 17.5.6, "Event Reports Generated in MySQL Cluster". These

log messages also correspond to log event types in the MGM API; see The Ndb_logevent_type Type, for related information of interest to Cluster API developers.

Log Message	Description	Event Name	Event Type	Priority	Severity
Node `mgm_node_id`: Node `data_node_id` Connected	The data node having node ID `node_id` has connected to the management server (node `mgm_node_id`).	`Connected`	`Connection`	8	`INFO`
Node `mgm_node_id`: Node `data_node_id` Disconnected	The data node having node ID `data_node_id` has disconnected from the management server (node `mgm_node_id`).	`Disconnected`	`Connection`	8	`ALERT`
Node `data_node_id`: Communication to Node `api_node_id` closed	The API node or SQL node having node ID `api_node_id` is no longer communicating with data node `data_node_id`.	`CommunicationClosed`	`Connection`	8	`INFO`
Node `data_node_id`: Communication to Node `api_node_id` opened	The API node or SQL node having node ID `api_node_id` is now communicating with data node `data_node_id`.	`CommunicationOpened`	`Connection`	8	`INFO`
Node `mgm_node_id`: Node `api_node_id`: API `version`	The API node having node ID `api_node_id` has connected to management node `mgm_node_id` using `NDB` API version `version` (generally the same as the MySQL version number).	`ConnectedApiVersion`	`Connection`	8	`INFO`
Node `node_id`: Global checkpoint `gci` started	A global checkpoint with the ID `gci` has been started; node `node_id` is the master responsible	`GlobalCheckpointStarted`	`Checkpoint`	9	`INFO`

Log Message	Description	Event Name	Event Type	Priority	Severity
	for this global checkpoint.				
Node *node_id*: Global checkpoint *gci* completed	The global checkpoint having the ID *gci* has been completed; node *node_id* was the master responsible for this global checkpoint.	GlobalCheckpointCompleted	Checkpoint	10	INFO
Node *node_id*: Local checkpoint *lcp* started. Keep GCI = *current_gci* oldest restorable GCI = *old_gci*	The local checkpoint having sequence ID *lcp* has been started on node *node_id*. The most recent GCI that can be used has the index *current_gci*, and the oldest GCI from which the cluster can be restored has the index *old_gci*.	LocalCheckpointStarted	Checkpoint	7	INFO
Node *node_id*: Local checkpoint *lcp* completed	The local checkpoint having sequence ID *lcp* on node *node_id* has been completed.	LocalCheckpointCompleted	Checkpoint	8	INFO

17.5.7.2 MySQL Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [all: %s connected: %s no-wait: %s]

- Waiting until nodes: %s connects, nodes [all: %s connected: %s no-wait: %s]

- Waiting %u sec for nodes %s to connect, nodes [all: %s connected: %s no-wait: %s]

- Waiting for non partitioned start, nodes [all: %s connected: %s missing: %s no-wait: %s]

- Waiting %u sec for non partitioned start, nodes [all: %s connected: %s missing: %s no-wait: %s]

- Initial start with nodes %s [missing: %s no-wait: %s]

- Start with all nodes %s

- Start with nodes %s [missing: %s no-wait: %s]

- Start potentially partitioned with nodes %s [missing: %s no-wait: %s]

- Unknown startreport: 0x%x [%s %s %s %s]

17.5.7.3 MySQL Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

Error Code	Error Name	Error Text
0x00	**TE_NO_ERROR**	No error
0x01	**TE_ERROR_CLOSING_SOCKET**	Error found during closing of socket
0x02	**TE_ERROR_IN_SELECT_BEFORE_ACCEPT**	Error found before accept. The transporter will retry
0x03	**TE_INVALID_MESSAGE_LENGTH**	Error found in message (invalid message length)
0x04	**TE_INVALID_CHECKSUM**	Error found in message (checksum)
0x05	**TE_COULD_NOT_CREATE_SOCKET**	Error found while creating socket(can't create socket)
0x06	**TE_COULD_NOT_BIND_SOCKET**	Error found while binding server socket
0x07	**TE_LISTEN_FAILED**	Error found while listening to server socket
0x08	**TE_ACCEPT_RETURN_ERROR**	Error found during accept(accept return error)
0x0b	**TE_SHM_DISCONNECT**	The remote node has disconnected
0x0c	**TE_SHM_IPC_STAT**	Unable to check shm segment
0x0d	**TE_SHM_UNABLE_TO_CREATE_SEGMENT**	Unable to create shm segment
0x0e	**TE_SHM_UNABLE_TO_ATTACH_SEGMENT**	Unable to attach shm segment
0x0f	**TE_SHM_UNABLE_TO_REMOVE_SEGMENT**	Unable to remove shm segment
0x10	**TE_TOO_SMALL_SIGID**	Sig ID too small
0x11	**TE_TOO_LARGE_SIGID**	Sig ID too large
0x12	**TE_WAIT_STACK_FULL**	Wait stack was full
0x13	**TE_RECEIVE_BUFFER_FULL**	Receive buffer was full
0x14	**TE_SIGNAL_LOST_SEND_BUFFER_FULL**	Send buffer was full,and trying to force send fails
0x15	**TE_SIGNAL_LOST**	Send failed for unknown reason(signal lost)

Error Code	Error Name	Error Text
0x16	**TE_SEND_BUFFER_FULL**	The send buffer was full, but sleeping for a while solved
0x0017	**TE_SCI_LINK_ERROR**	There is no link from this node to the switch
0x18	**TE_SCI_UNABLE_TO_START_SEQUENCE**	Could not start a sequence, because system resources are exumed or no sequence has been created
0x19	**TE_SCI_UNABLE_TO_REMOVE_SEQUENCE**	Could not remove a sequence
0x1a	**TE_SCI_UNABLE_TO_CREATE_SEQUENCE**	Could not create a sequence, because system resources are exempted. Must reboot
0x1b	**TE_SCI_UNRECOVERABLE_DATA_TFX_ERROR**	Tried to send data on redundant link but failed
0x1c	**TE_SCI_CANNOT_INIT_LOCALSEGMENT**	Cannot initialize local segment
0x1d	**TE_SCI_CANNOT_MAP_REMOTESEGMENT**	Cannot map remote segment
0x1e	**TE_SCI_UNABLE_TO_UNMAP_SEGMENT**	Cannot free the resources used by this segment (step 1)
0x1f	**TE_SCI_UNABLE_TO_REMOVE_SEGMENT**	Cannot free the resources used by this segment (step 2)
0x20	**TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT**	Cannot disconnect from a remote segment
0x21	**TE_SHM_IPC_PERMANENT**	Shm ipc Permanent error
0x22	**TE_SCI_UNABLE_TO_CLOSE_CHANNEL**	Unable to close the sci channel and the resources allocated

17.5.8 MySQL Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. Beginning with MySQL Cluster NDB 7.1.1, you can also check the `status` column of the `ndbinfo.nodes` table (see Section 17.5.10.13, "The ndbinfo nodes Table", for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

> **Note**
>
> When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

• Method 1:

  1. Finish all single user mode transactions

  2. Issue the `EXIT SINGLE USER MODE` command

  3. Restart the cluster's data nodes

• Method 2:

  Restart database nodes prior to entering single user mode.

17.5.9 Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

• `SHOW ENGINE NDB STATUS`, `SHOW ENGINE NDBCLUSTER STATUS`

  The output of this statement contains information about the server's connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

  See Section 13.7.5.16, "SHOW ENGINE Syntax", for a usage example and more detailed information.

• `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See Section 13.7.5.17, "SHOW ENGINES Syntax", for more detailed information.

> **Note**
>
> In MySQL 5.1 and later, this statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES` table, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

  This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database (available beginning with MySQL 5.1.5). Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

  ```
  mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
      ->    WHERE ENGINE LIKE 'NDB%';
  +---------+
  | support |
  +---------+
  | ENABLED |
  +---------+
  ```

  See Section 20.6, "The INFORMATION_SCHEMA ENGINES Table", for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

  This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

  ```
  mysql> SHOW VARIABLES LIKE 'NDB%';
  +-----------------------------------+-------+
  | Variable_name                     | Value |
  +-----------------------------------+-------+
  | ndb_autoincrement_prefetch_sz     | 32    |
  | ndb_cache_check_time              | 0     |
  | ndb_extra_logging                 | 0     |
  | ndb_force_send                    | ON    |
  | ndb_index_stat_cache_entries      | 32    |
  | ndb_index_stat_enable             | OFF   |
  | ndb_index_stat_update_freq        | 20    |
  | ndb_report_thresh_binlog_epoch_slip | 3   |
  | ndb_report_thresh_binlog_mem_usage | 10   |
  | ndb_use_copying_alter_table       | OFF   |
  | ndb_use_exact_count               | ON    |
  | ndb_use_transactions              | ON    |
  +-----------------------------------+-------+
  ```

  See Section 5.1.4, "Server System Variables", for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';`

  This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
    ->   WHERE VARIABLE_NAME LIKE 'NDB%';
+------------------------------------+----------------+
| VARIABLE_NAME                      | VARIABLE_VALUE |
+------------------------------------+----------------+
| NDB_AUTOINCREMENT_PREFETCH_SZ      | 32             |
| NDB_CACHE_CHECK_TIME               | 0              |
| NDB_EXTRA_LOGGING                  | 0              |
| NDB_FORCE_SEND                     | ON             |
| NDB_INDEX_STAT_CACHE_ENTRIES       | 32             |
| NDB_INDEX_STAT_ENABLE              | OFF            |
| NDB_INDEX_STAT_UPDATE_FREQ         | 20             |
| NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP | 3             |
| NDB_REPORT_THRESH_BINLOG_MEM_USAGE | 10             |
| NDB_USE_COPYING_ALTER_TABLE        | OFF            |
| NDB_USE_EXACT_COUNT                | ON             |
| NDB_USE_TRANSACTIONS               | ON             |
+------------------------------------+----------------+
```

Unlike the case with the SHOW command, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
    ->   FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
    ->   WHERE VARIABLE_NAME = 'ndb_force_send';
+----------------+
| VARIABLE_VALUE |
+----------------+
| ON             |
+----------------+
```

See Section 20.9, "The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables", and Section 5.1.4, "Server System Variables", for more information.

- SHOW STATUS LIKE 'NDB%'

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
+--------------------------+---------------+
| Variable_name            | Value         |
+--------------------------+---------------+
| Ndb_cluster_node_id      | 10            |
| Ndb_config_from_host     | 192.168.0.103 |
| Ndb_config_from_port     | 1186          |
| Ndb_number_of_data_nodes | 4             |
+--------------------------+---------------+
```

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| Ndb_cluster_node_id      | 0     |
| Ndb_config_from_host     |       |
| Ndb_config_from_port     | 0     |
| Ndb_number_of_data_nodes | 0     |
```

```
+-------------------------+-------+
```

See also Section 13.7.5.37, "SHOW STATUS Syntax".

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';`

  Beginning with MySQL 5.1.12, this statement provides similar output to the `SHOW` command discussed in the previous item. However, unlike the case with `SHOW STATUS`, it is possible using the `SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

  See Section 20.8, "The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables", for more information.

Beginning with MySQL Cluster NDB 7.1.1, you can also query the tables in the `ndbinfo` information database for real-time data about many MySQL Cluster operations. See Section 17.5.10, "The ndbinfo MySQL Cluster Information Database".

17.5.10 The ndbinfo MySQL Cluster Information Database

`ndbinfo` is a database containing information specific to MySQL Cluster, available beginning with MySQL Cluster NDB 7.1.1.

This database contains a number of tables, each providing a different sort of data about MySQL Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with MySQL Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+------------+----------+----------------+---------+---------+
| Name       | Status   | Type           | Library | License |
+------------+----------+----------------+---------+---------+
| binlog     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| partition  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ARCHIVE    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| BLACKHOLE  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| CSV        | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| FEDERATED  | DISABLED | STORAGE ENGINE | NULL    | GPL     |
| MEMORY     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| InnoDB     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MyISAM     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MRG_MYISAM | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ndbcluster | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ndbinfo    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
+------------+----------+----------------+---------+---------+
12 rows in set (0.00 sec)
```

You can also do this by checking the output of `SHOW ENGINES` for a row that has `ndbinfo` for `Engine` and `YES` for `Support`, as shown here (emphasized text):

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: ndbcluster
     Support: YES
     Comment: Clustered, fault-tolerant tables
```

```
Transactions: YES
          XA: NO
   Savepoints: NO
*************************** 2. row ***************************
      Engine: MRG_MYISAM
     Support: YES
     Comment: Collection of identical MyISAM tables
Transactions: NO
          XA: NO
   Savepoints: NO
*************************** 3. row ***************************
      Engine: ndbinfo
     Support: YES
     Comment: MySQL Cluster system information storage engine
Transactions: NO
          XA: NO
   Savepoints: NO
*************************** 4. row ***************************
      Engine: CSV
     Support: YES
     Comment: CSV storage engine
Transactions: NO
          XA: NO
   Savepoints: NO
*************************** 5. row ***************************
      Engine: MEMORY
     Support: YES
     Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
          XA: NO
   Savepoints: NO
*************************** 6. row ***************************
      Engine: FEDERATED
     Support: NO
     Comment: Federated MySQL storage engine
Transactions: NULL
          XA: NULL
   Savepoints: NULL
*************************** 7. row ***************************
      Engine: ARCHIVE
     Support: YES
     Comment: Archive storage engine

          XA: NO
   Savepoints: NO
*************************** 8. row ***************************
      Engine: InnoDB
     Support: YES
     Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
          XA: YES
   Savepoints: YES
*************************** 9. row ***************************
      Engine: MyISAM
     Support: DEFAULT
     Comment: Default engine as of MySQL 3.23 with great performance
Transactions: NO
          XA: NO
   Savepoints: NO
*************************** 10. row ***************************
      Engine: BLACKHOLE
     Support: YES
     Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
          XA: NO
   Savepoints: NO
10 rows in set (0.00 sec)
```

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| test               |
+--------------------+
4 rows in set (0.00 sec)
```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to a MySQL Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` "tables" are actually views generated from internal `NDB` tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, `ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+----------------------+
| Tables_in_ndbinfo    |
+----------------------+
| blocks               |
| cluster_operations   |
| cluster_transactions |
| config_params        |
| counters             |
| diskpagebuffer       |
| logbuffers           |
| logspaces            |
| memoryusage          |
| nodes                |
| resources            |
| server_operations    |
| server_transactions  |
| threadblocks         |
| threadstat           |
```

```
| transporters         |
+----------------------+
16 rows in set (0.04 sec)
```

The `diskpagebuffer` table was added in MySQL Cluster NDB 7.1.9.

The `cluster_operations`, `cluster_transactions`, `server_operations`, `server_transactions`, `threadblocks`, and `threadstat` tables were added in MySQL Cluster NDB 7.1.17.

In early versions of MySQL Cluster NDB 7.1, there was an additional `pools` table in the `ndbinfo` database; however, this table was removed in MySQL Cluster NDB 7.1.3.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```
mysql> SELECT * FROM memoryusage;
+---------+---------------------+--------+------------+------------+-------------+
| node_id | memory_type         | used   | used_pages | total      | total_pages |
+---------+---------------------+--------+------------+------------+-------------+
|       5 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       5 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       5 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
|       6 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       6 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       6 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
+---------+---------------------+--------+------------+------------+-------------+
6 rows in set (0.02 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
    >      FROM memoryusage
    >      WHERE memory_type = 'Data memory';
+-----------------------------+
| Data Memory Used, All Nodes |
+-----------------------------+
|                        6460 |
+-----------------------------+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
    >      FROM memoryusage
    >      WHERE memory_type = 'Index memory';
+-----------------------------+
| Total IndexMemory Available |
+-----------------------------+
|                       25664 |
+-----------------------------+
1 row in set (0.33 sec)
```

`ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+
| node_id | uptime | status  | start_phase |
+---------+--------+---------+-------------+
|       1 |  13602 | STARTED |           0 |
|       2 |     16 | STARTED |           0 |
```

```
+---------+--------+---------+-------------+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

Beginning with MySQL Cluster NDB 7.1.7, `mysqldump` ignores `ndbinfo` entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

MySQL Cluster also maintains tables in the `INFORMATION_SCHEMA` information database, including the `FILES` table which contains information about files used for MySQL Cluster Disk Data storage. For more information, see Section 20.26, "INFORMATION_SCHEMA Tables for MySQL Cluster".

17.5.10.1 The ndbinfo arbitrator_validity_detail Table

The `arbitrator_validity_detail` table shows the view that each data node in the cluster of the arbitrator. It is a subset of the `membership` table.

The following table provides information about the columns in the `arbitrator_validity_detail` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
node_id	integer	This node's node ID
arbitrator	integer	Node ID of arbitrator
arb_ticket	string	Internal identifier used to track arbitration
arb_connected	Yes or No	Whether this node is connected to the arbitrator
arb_state	Enumeration (see text)	Arbitration state

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitrator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the `arbitrator`.

Like the `membership` and `arbitrator_validity_summary` tables, this table was added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26.

17.5.10.2 The ndbinfo arbitrator_validity_summary Table

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The following table provides information about the columns in the `arbitrator_validity_summary` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
arbitrator	integer	Node ID of arbitrator

Column Name	Type	Description
arb_ticket	string	Internal identifier used to track arbitration
arb_connected	Yes or No	Whether this arbitrator is connected to the cluster
consensus_count	integer	Number of data nodes that see this node as arbitrator

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The `arbitrator` column shows the arbitrator's node ID.

`arb_ticket` is the internal identifier used by this arbitrator.

`arb_connected` shows whether this node is connected to the cluster as an arbitrator.

Like the `membership` and `arbitrator_validity_detail` tables, this table was added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26.

17.5.10.3 The ndbinfo blocks Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the `blocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
block_number	integer	Block number
block_name	string	Block name

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different MySQL Cluster releases.

17.5.10.4 The ndbinfo cluster_operations Table

The `cluster_operations` table provides a per-operation (stateful primary key op) view of all activity in the MySQL Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The following table provides information about the columns in the `cluster_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
node_id	integer	Node ID of reporting LQH block

Column Name	Type	Description
block_instance	integer	LQH block instance
transid	integer	Transaction ID
operation_type	string	Operation type (see text for possible values)
state	string	Operation state (see text for possible values)
tableid	integer	Table ID
fragmentid	integer	Fragment ID
client_node_id	integer	Client node ID
client_block_ref	integer	Client block reference
tc_node_id	integer	Transaction coordinator node ID
tc_block_no	integer	Transaction coordinator block number
tc_block_instance	integer	Transaction coordinator block instance

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The operation_type column can take any one of the values READ, READ-SH, READ-EX, INSERT, UPDATE, DELETE, WRITE, UNLOCK, REFRESH, SCAN, SCAN-SH, SCAN-EX, or <unknown>.

The state column can have any one of the values ABORT_QUEUED, ABORT_STOPPED, COMMITTED, COMMIT_QUEUED, COMMIT_STOPPED, COPY_CLOSE_STOPPED, COPY_FIRST_STOPPED, COPY_STOPPED, COPY_TUPKEY, IDLE, LOG_ABORT_QUEUED, LOG_COMMIT_QUEUED, LOG_COMMIT_QUEUED_WAIT_SIGNAL, LOG_COMMIT_WRITTEN, LOG_COMMIT_WRITTEN_WAIT_SIGNAL, LOG_QUEUED, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_RELEASE_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFTER_ABORT, WAIT_ATTR, WAIT_SCAN_AI, WAIT_TUP, WAIT_TUPKEYINFO, WAIT_TUP_COMMIT, or WAIT_TUP_TO_ABORT. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb $dblqh_tcconnect_state table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of ndb_show_tables.

The fragid is the same as the partition number seen in the output of ndb_desc --extra-partition-info (short form -p).

In client_node_id and client_block_ref, client refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

17.5.10.5 The ndbinfo cluster_transactions Table

The cluster_transactions table shows information about all ongoing transactions in a MySQL Cluster.

The following table provides information about the columns in the cluster_transactions table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
node_id	integer	Node ID of transaction coordinator
block_instance	integer	TC block instance
transid	integer	Transaction ID
state	string	Operation state (see text for possible values)
count_operations	integer	Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)
outstanding_operations	integer	Operations still being executed in local data management blocks
inactive_seconds	integer	Time spent waiting for API
client_node_id	integer	Client node ID
client_block_ref	integer	Client block reference

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

17.5.10.6 The ndbinfo config_params Table

The `config_params` table is a static table which provides the names and internal ID numbers of all MySQL Cluster configuration parameters.

The following table provides information about the columns in the `config_params` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
param_number	integer	The parameter's internal ID number
param_name	string	The name of the parameter

Although this is a static table, its content can vary between MySQL Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

17.5.10.7 The ndbinfo counters Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The following table provides information about the columns in the `counters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
`node_id`	integer	The data node ID
`block_name`	string	Name of the associated NDB kernel block (see NDB Kernel Blocks).
`block_instance`	integer	Block instance
`counter_id`	integer	The counter's internal ID number; normally an integer between 1 and 10, inclusive.
`counter_name`	string	The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.
`val`	integer	The counter's value

Each counter is associated with a particular NDB kernel block. Prior to MySQL Cluster NDB 7.2.0, this was limited to either the `DBLQH` kernel block or the `DBTC` kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block (see The DBLQH Block). A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in `DBLQH` per operation in `DBTC`. For writes, there is one operation counted per replica.

The `ATTRINFO`, `TRANSACTIONS`, `COMMITS`, `READS`, `LOCAL_READS`, `SIMPLE_READS`, `WRITES`, `LOCAL_WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the DBTC (transaction co-ordinator) kernel block (see The DBTC Block).

`LOCAL_WRITES` and `LOCAL_READS` are primary-key operations using a transaction coordinator in a node that also holds the primary replica of the record.

The `READS` counter includes all reads. `LOCAL_READS` includes only those reads of the primary replica on the same node as this transaction coordinator. `SIMPLE_READS` includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are "simple" from the point of view of the TC block; since they hold no locks they are not durable, and once `DBTC` has routed them to the relevant LQH block, it holds no state for them.

`ATTRINFO` keeps a count of the number of times an interpreted program is sent to the data node. See NDB Protocol Messages, for more information about `ATTRINFO` messages in the `NDB` kernel.

MySQL Cluster NDB 7.2.0, as part of its implementation of distributed pushed-down joins, adds the `LOCAL_TABLE_SCANS_SENT`, `READS_RECEIVED`, `PRUNED_RANGE_SCANS_RECEIVED`, `RANGE_SCANS_RECEIVED`, `LOCAL_READS_SENT`, `CONST_PRUNED_RANGE_SCANS_RECEIVED`, `LOCAL_RANGE_SCANS_SENT`, `REMOTE_READS_SENT`, `REMOTE_RANGE_SCANS_SENT`,

`READS_NOT_FOUND`, `SCAN_BATCHES_RETURNED`, `TABLE_SCANS_RECEIVED`, and `SCAN_ROWS_RETURNED` counters. These counters are associated with the `DBSPJ` (select push-down join) kernel block (see The DBSPJ Block).

A number of counters increasing the visibility of transporter overload and send buffer sizing when troubleshooting such issues were added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26. (Bug #15935206) For each LQH instance, there is one instance of each counter in the following list:

- `LQHKEY_OVERLOAD`: Number of primary key requests rejected at the LQH block instance due to transporter overload

- `LQHKEY_OVERLOAD_TC`: Count of instances of `LQHKEY_OVERLOAD` where the TC node transporter was overloaded

- `LQHKEY_OVERLOAD_READER`: Count of instances of `LQHKEY_OVERLOAD` where the API reader (reads only) node was overloaded.

- `LQHKEY_OVERLOAD_NODE_PEER`: Count of instances of `LQHKEY_OVERLOAD` where the next backup data node (writes only) was overloaded

- `LQHKEY_OVERLOAD_SUBSCRIBER`: Count of instances of `LQHKEY_OVERLOAD` where a event subscriber (writes only) was overloaded.

- `LQHSCAN_SLOWDOWNS`: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

17.5.10.8 The ndbinfo diskpagebuffer Table

The `diskpagebuffer` table provides statistics about disk page buffer usage by MySQL Cluster Disk Data tables.

The following table provides information about the columns in the `diskpagebuffer` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
`node_id`	integer	The data node ID
`block_instance`	integer	Block instance
`pages_written`	integer	Number of pages written to disk.
`pages_written_lcp`	integer	Number of pages written by local checkpoints.
`pages_read`	integer	Number of pages read from disk
`log_waits`	integer	Number of page writes waiting for log to be written to disk
`page_requests_direct_return`	integer	Number of requests for pages that were available in buffer
`page_requests_wait_queue`	integer	Number of requests that had to wait for pages to become available in buffer
`page_requests_wait_io`	integer	Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

You can use this table with MySQL Cluster Disk Data tables to determine whether `DiskPageBufferMemory` is sufficiently large to allow data to be read from the buffer rather from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return /
    (page_requests_direct_return + page_requests_wait_io)
      AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+---------+-----------+
| node_id | hit_ratio |
+---------+-----------+
|       5 |   97.6744 |
|       6 |   97.6879 |
|       7 |   98.1776 |
|       8 |   98.1343 |
+---------+-----------+
4 rows in set (0.00 sec)
```

`hit_ratio` values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for `DiskPageBufferMemory` needs to be increased in the `config.ini` file.

Note

A change in `DiskPageBufferMemory` requires a rolling restart of all of the cluster's data nodes before it takes effect.

17.5.10.9 The ndbinfo logbuffers Table

The `logbuffer` table provides information on MySQL Cluster log buffer usage.

The following table provides information about the columns in the `logbuffers` table. For each column, the table shows the name, data type, and a brief description.

Column Name	Type	Description
node_id	integer	The ID of this data node.
log_type	string	Type of log; one of: `REDO` or `DD-UNDO`.
log_id	integer	The log ID.
log_part	integer	The log part number.
total	integer	Total space available for this log.
used	integer	Space used by this log.

17.5.10.10 The ndbinfo logspaces Table

This table provides information about MySQL Cluster log space usage.

The following table provides information about the columns in the `logspaces` table. For each column, the table shows the name, data type, and a brief description.

Column Name	Type	Description
`node_id`	integer	The ID of this data node.
`log_type`	string	Type of log; one of: `REDO` or `DD-UNDO`.
`log_id`	integer	The log ID.
`log_part`	integer	The log part number.
`total`	integer	Total space available for this log.
`used`	integer	Space used by this log.

17.5.10.11 The ndbinfo membership Table

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The following table provides information about the columns in the `membership` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
`node_id`	integer	This node's node ID
`group_id`	integer	Node group to which this node belongs
`left node`	integer	Node ID of the previous node
`right_node`	integer	Node ID of the next node
`president`	integer	President's node ID
`successor`	integer	Node ID of successor to president
`succession_order`	integer	Order in which this node succeeds to presidency
`Conf_HB_order`	integer	-
`arbitrator`	integer	Node ID of arbitrator
`arb_ticket`	string	Internal identifier used to track arbitration
`arb_state`	Enumeration (see text)	Arbitration state
`arb_connected`	`Yes` or `No`	Whether this node is connected to the arbitrator
`connected_rank1_arbs`	List of node IDs	Connected arbitrators of rank 1
`connected_rank2_arbs`	List of node IDs	Connected arbitrators of rank 1

The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

`left_node` and `right_node` are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

Figure 17.9 Circular Arrangement of MySQL Cluster Nodes
In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine "left" and "right" from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id,left_node,right_node
    -> FROM ndbinfo.membership;
+---------+-----------+------------+
| node_id | left_node | right_node |
+---------+-----------+------------+
|       5 |        15 |          6 |
|       6 |         5 |          7 |
|       7 |         6 |          8 |
|       8 |         7 |         12 |
|      12 |         8 |         13 |
|      13 |        12 |         14 |
|      14 |        13 |         15 |
|      15 |        14 |          5 |
+---------+-----------+------------+
8 rows in set (0.00 sec)
```

The designations "left" and "right" are used in the event log in the same way.

The `president` node is the node viewed by the current node as responsible for setting an arbitrator (see MySQL Cluster Start Phases). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the `successor` column to become the new president. The `succession_order` column shows the place in the succession queue that the current node views itself as having.

In a normal MySQL Cluster, all data nodes should see the same node as `president`, and the same node (other than the president) as its `successor`. In addition, the current president should see itself as `1` in the order of succession, the `successor` node should see itself as `2`, and so on.

All nodes should show the same `arb_ticket` values as well as the same `arb_state` values. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether this node is connected to the node shown as this node's `arbitrator`.

The `connected_rank1_arbs` and `connected_rank2_arbs` columns each display a list of 0 or more arbitrators having an `ArbitrationRank` equal to 1, or to 2, respectively.

> **Note**
>
> Both management nodes and API nodes are eligible to become arbitrators.

Like the `arbitrator_validity_detail` and `arbitrator_validity_summary` tables, this table was added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26.

17.5.10.12 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The following table provides information about the columns in the `memoryusage` table in MySQL Cluster NDB 7.1.3 and later. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
`node_id`	integer	The node ID of this data node.
`memory_type`	string	One of `Data memory`, `Index memory`, or (*MySQL Cluster NDB 7.1.31 and later*) `Long message buffer`.
`used`	integer	Number of bytes currently used for data memory or index memory by this data node.
`used_pages`	integer	Number of pages currently used for data memory or index memory by this data node; see text.
`total`	integer	Total number of bytes of data memory or index memory available for this data node; see text.
`total_pages`	integer	Total number of memory pages available for data memory or index memory on this data node; see text.

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs `5` and `6`, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB in MySQL Cluster NDB 7.1.31 and later).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
     > FROM ndbinfo.memoryusage;
```

```
+---------+---------------------+------------+
| node_id | memory_type         | total      |
+---------+---------------------+------------+
|       5 | Data memory         | 1073741824 |
|       5 | Index memory        | 1074003968 |
|       5 | Long message buffer |   67108864 |
|       6 | Data memory         | 1073741824 |
|       6 | Index memory        | 1074003968 |
|       6 | Long message buffer |   67108864 |
+---------+---------------------+------------+
6 rows in set (0.00 sec)
```

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

Long message buffer information can be found in this table beginning with MySQL Cluster NDB 7.1.31; in earlier versions, only data memory and index memory were included.

MySQL Cluster NDB 7.1.2 and earlier.   The remainder of this section provides information about the `memoryusage` table as implemented prior to MySQL Cluster NDB 7.1.3. (If you are using MySQL Cluster NDB 7.1.3 or later, refer to the beginning of this section.) For each column, the table shown here provides the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
node_id	integer	The node ID of this data node.
memory_type	string	One of `Data memory` or `Index memory`
used	integer	Number of memory pages used; see text.
max	integer	Total number of memory pages available; see text.

For the `used` and `max` columns, resources are measured in pages, which (in MySQL Cluster NDB 7.1.2 and earlier) are 16K in size for `DataMemory` and 8K for `IndexMemory`. This example shows how to use this information in obtaining totals for `DataMemory`, `IndexMemory`, or both, which you can do by summing across data nodes and table columns, like this:

```
mysql> USE ndbinfo;
Database changed
mysql> SET @IPAGE := 8 * 1024;
Query OK, 0 rows affected (0.03 sec)

mysql> SET @DPAGE := 2 * @IPAGE;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT
    ->      @DPAGE * SUM(used) as 'Total DataMemory Used',
    ->      @DPAGE * SUM(max) as 'Total DataMemory Available',
    ->      @DPAGE * SUM(used) DIV COUNT(*) as 'Average DataMemory Used Per Node',
    ->      @DPAGE * SUM(max) DIV COUNT(*) as 'Average DataMemory Available Per Node'
    ->          FROM memoryusage WHERE memory_type = 'Data memory'\G
*************************** 1. row ***************************
          Total DataMemory Used: 106102784
     Total DataMemory Available: 209977344
```

```
      Average DataMemory Used Per Node: 53051392
 Average DataMemory Available Per Node: 104988672
1 row in set (0.34 sec)

mysql> SELECT
    ->      @IPAGE * SUM(used) as 'Total IndexMemory Used',
    ->      @IPAGE * SUM(max) as 'Total IndexMemory Available',
    ->      @IPAGE * SUM(used) DIV COUNT(*) as 'Average IndexMemory Used Per Node',
    ->      @IPAGE * SUM(max) DIV COUNT(*) as 'Average IndexMemory Available Per Node'
    ->      FROM memoryusage WHERE memory_type = 'INDEX_MEMORY'\G
*************************** 1. row ***************************
             Total IndexMemory Used: 376832
        Total IndexMemory Available: 210239488
     Average IndexMemory Used Per Node: 188416
 Average IndexMemory Available Per Node: 105119744
1 row in set (0.33 sec)
```

(We use `DIV` rather than `/` in both queries so that the results in all of the output columns are integers.)

Prior to MySQL Cluster NDB 7.1.2, the `memory_type` column was named `DATA_MEMORY`. (Bug #50926)

17.5.10.13 The ndbinfo nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
node_id	integer	The data node's unique node ID in the cluster.
uptime	integer	Time since the node was last started, in seconds.
status	string	Current status of the data node; see text for possible values.
start_phase	integer	If the data node is starting, the current start phase.
config_generation	integer	The version of the cluster configuration file in use on this data node.

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a non-zero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see Section 17.5.8, "MySQL Cluster Single User Mode"). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state; for example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client *node_id* `STATUS` command (see Section 17.5.2, "Commands in the MySQL Cluster Management Client"). If the node is not currently starting, then this column shows `0`. For a listing of MySQL Cluster start phases with descriptions, see Section 17.5.1, "Summary of MySQL Cluster Start Phases".

The `config_generation` column was added in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. This column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (`6`) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  10462 | STARTED |           0 |                 6 |
|       2 |  10460 | STARTED |           0 |                 6 |
|       3 |  10457 | STARTED |           0 |                 5 |
|       4 |  10455 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

> **Note**
>
> When upgrading to MySQL Cluster NDB 7.0.24 or MySQL Cluster NDB 7.1.13 from a previous version of MySQL Cluster, you should run `mysql_upgrade` on all MySQL Servers that should connect to the cluster, in order to enable support for the new `config_generation` column. Otherwise, when you attempt to access this table, you get the warning `Table 'ndb$nodes' is defined differently in NDB, there are more columns available...`

Nodes that are stopped are not accounted for in this table. Suppose that you have a MySQL Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11776 | STARTED |           0 |                 6 |
|       2 |  11774 | STARTED |           0 |                 6 |
|       3 |  11771 | STARTED |           0 |                 6 |
|       4 |  11769 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
```

```
Node 2 has shutdown.
```

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11807 | STARTED |           0 |                 6 |
|       3 |  11802 | STARTED |           0 |                 6 |
|       4 |  11800 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
3 rows in set (0.02 sec)
```

17.5.10.14 The ndbinfo pools Table

> **Important**
>
> This table was part of the original `ndbinfo` implementation, but was later removed (in MySQL Cluster NDB 7.1.3). The information in this section is now obsolete, and subject to removal in a future version of the documentation.

The `pools` table was originally intended to provide information about `NDB` memory pool usage, but was later removed.

For each column, this table shows the name, data type, and a brief description of each `ndbinfo.pools` column (as it appeared prior to MySQL Cluster NDB 7.1.3). Additional information can be found in the notes afterward.

Column Name	Type	Description
`node_id`	integer	The data node's node ID.
`block_name`	string	Name of the NDB kernel block using this pool.
`block_instance`	integer	Kernel block instance ID.
`pool_name`	string	The name of the pool.
`used`	integer	Amount of the pool in use.
`total`	integer	Total size of the pool.
`high`	integer	The maximum used from this pool (since the node was last started).
`entry_size`	integer	The size of each object, in bytes.
`param_name1`	string	Name of a configuration parameter associated with this pool (or `NULL`); see text.
`param_name2`	string	Name of a configuration parameter associated with this pool (or `NULL`); see text.
`param_name3`	string	Name of a configuration parameter associated with this pool (or `NULL`); see text.
`param_name4`	string	Name of a configuration parameter associated with this pool (or `NULL`); see text.

The columns `param_name1`, `param_name2`, `param_name3`, and `param_name4` contain names of configuration parameters that are associated with a given pool. If no parameters are associated with the pool, then all 4 of these columns are `NULL`. For pools that are associated with configuration parameters, these columns are filled with non-`NULL` values, but not in any particular order.

You can use a query such as the one shown here to generate a table showing the associations of pools, NDB kernel blocks, and (where applicable) configuration parameters:

```
SELECT
    DISTINCT(pool_name) as 'Pool',
    block_name as 'Block',
    IF(
        (param_name1 && param_name2 && param_name3 && param_name4) IS NULL,
        '[NONE]',
        REPLACE(
            TRIM(
                CONCAT(
                    IFNULL(param_name1, ''),
                    IFNULL(CONCAT(' ', param_name2), ''),
                    IFNULL(CONCAT(' ', param_name3), ''),
                    IFNULL(CONCAT(' ', param_name4), '')
                )
            ), ' ', ', '
        )
    ) as 'Parameter(s)'
FROM pools ORDER BY pool_name;
```

You may also find the following stored procedure useful. It returns a list of pools associated with a given configuration parameter, along with the kernel blocks to which these pools belong. You can see here the statement used to create this stored procedure along with sample output for some typical parameters:

```
mysql> DELIMITER |
mysql> CREATE PROCEDURE get_pools (p VARCHAR(50))
    -> BEGIN
    ->     SELECT
    ->         DISTINCT(pool_name) as Pool,
    ->         block_name as Block
    ->     FROM ndbinfo.pools
    ->     WHERE p
    ->         IN (param_name1, param_name2, param_name3, param_name4)
    .>     ORDER BY Pool;
    -> END
    -> |
Query OK, 0 rows affected (0.02 sec)

mysql> DELIMITER ;

mysql> CALL get_pools('MaxNoOfTables');
+-----------------+------------+
| pool_name       | block_name |
+-----------------+------------+

```

17.5.10.15 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The following table provides information about the columns in the `resources` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
node_id	integer	The unique node ID of this data node.
resource_name	string	Name of the resource; see text.
reserved	integer	The amount reserved for this resource.
used	integer	The amount actually used by this resource.
max	integer	The maximum amount of this resource used, since the node was last started.

The `resource_name` can be one of `RESERVED`, `DISK_OPERATIONS`, `DISK_RECORDS`, `DATA_MEMORY`, `JOBBUFFER`, `FILE_BUFFERS`, or `TRANSPORTER_BUFFERS`.

17.5.10.16 The ndbinfo server_operations Table

The `server_operations` table contains entries for all ongoing `NDB` operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The following table provides information about the columns in the `server_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
mysql_connection_id	integer	MySQL Server connection ID
node_id	integer	Node ID
block_instance	integer	Block instance
transid	integer	Transaction ID
operation_type	string	Operation type (see text for possible values)
state	string	Operation state (see text for possible values)

Column Name	Type	Description
`tableid`	integer	Table ID
`fragmentid`	integer	Fragment ID
`client_node_id`	integer	Client node ID
`client_block_ref`	integer	Client block reference
`tc_node_id`	integer	Transaction coordinator node ID
`tc_block_no`	integer	Transaction coordinator block number
`tc_block_instance`	integer	Transaction coordinator block instance

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an `NDB` table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

17.5.10.17 The ndbinfo server_transactions Table

The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The following table provides information about the columns in the `server_transactions` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
`mysql_connection_id`	integer	MySQL Server connection ID
`node_id`	integer	Transaction coordinator node ID
`block_instance`	integer	Transaction coordinator block instance
`transid`	integer	Transaction ID
`state`	string	Operation state (see text for possible values)
`count_operations`	integer	Number of stateful operations in the transaction
`outstanding_operations`	integer	Operations still being executed by local data management layer (LQH blocks)
`inactive_seconds`	integer	Time spent waiting for API
`client_node_id`	integer	Client node ID
`client_block_ref`	integer	Client block reference

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

17.5.10.18 The ndbinfo threadblocks Table

The `threadblocks` table associates data nodes, threads, and instances of `NDB` kernel blocks.

The following table provides information about the columns in the `threadblocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
`node_id`	integer	Node ID
`thr_no`	integer	Thread ID
`block_name`	string	Block name

Column Name	Type	Description
`block_instance`	integer	Block instance number

The `block_name` is one of the values found in the `block_name` column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given MySQL Cluster release, the list may vary between releases.

This table was added in MySQL Cluster NDB 7.1.17.

17.5.10.19 The ndbinfo threadstat Table

The `threadstat` table provides a rough snapshot of statistics for threads running in the `NDB` kernel.

The following table provides information about the columns in the `threadstat` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
`node_id`	integer	Node ID
`thr_no`	integer	Thread ID
`thr_nm`	string	Thread name
`c_loop`	string	Number of loops in main loop
`c_exec`	string	Number of signals executed
`c_wait`	string	Number of times waiting for additional input
`c_l_sent_prioa`	integer	Number of priority A signals sent to own node
`c_l_sent_priob`	integer	Number of priority B signals sent to own node
`c_r_sent_prioa`	integer	Number of priority A signals sent to remote node
`c_r_sent_priob`	integer	Number of priority B signals sent to remote node
`os_tid`	integer	OS thread ID
`os_now`	integer	OS time (ms)
`os_ru_utime`	integer	OS user CPU time (µs)
`os_ru_stime`	integer	OS system CPU time (µs)
`os_ru_minflt`	integer	OS page reclaims (soft page faults)
`os_ru_majflt`	integer	OS page faults (hard page faults)
`os_ru_nvcsw`	integer	OS voluntary context switches
`os_ru_nivcsw`	integer	OS involuntary context switches

`os_time` uses the system `gettimeofday()` call.

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcsw`, and `os_ru_nivcsw` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event

Scheduler can be employed to automate such monitoring. For more information, see Section 19.4, "Using the Event Scheduler".

This table was added in MySQL Cluster NDB 7.1.17.

17.5.10.20 The ndbinfo transporters Table

This table contains information about `NDB` transporters.

The following table provides information about the columns in the `transporters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Description
`node_id`	integer	This data node's unique node ID in the cluster.
`remote_node_id`	integer	The remote data node's node ID.
`status`	string	Status of the connection.
`remote_address`	string	Name or IP address of the remote host
`bytes_sent`	integer	Number of bytes sent using this connection
`bytes_received`		Number of bytes received using this connection
`connect_count`		Number of times connection established on this transporter
`overloaded`		1 if this transporter is currently overloaded, otherwise 0
`overload_count`		Number of times this transporter has entered overload state since connecting
`slowdown`		1 if this transporter is in scan slowdown state, otherwise 0
`slowdown_count`		Number of times this transporter has entered scan slowdown state since connecting

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's *status* column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data nodes which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

The `remote_address`, `bytes_sent`, and `bytes_received` columns were added in MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25. The `remote_address` is the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established; for nodes whose status is `CONNECTING` or `DISCONNECTED`, these columns always display `0`.

The `connect_count`, `overloaded`, `overload_count` ,`slowdown`, and `slowdown_count` columns were added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26. These counters are reset on

connection, and retain their values after the remote node disconnects. Also beginning with MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26, the `bytes_send` and `bytes_received` counters are reset on connection as well, and so retain their values following disconnection. (Previously, the values in these columns were reset on disconnection.) (Bug #15935206)

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @10.100.10.1  (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2    @10.100.10.2  (5.1.77-ndb-7.1.37, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @10.100.10.10  (5.1.77-ndb-7.1.37)

[mysqld(API)]    2 node(s)
id=20   @10.100.10.20  (5.1.77-ndb-7.1.37)
id=21   @10.100.10.21  (5.1.77-ndb-7.1.37)
```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    ->   FROM ndbinfo.transporters;
+---------+----------------+--------------+
| node_id | remote_node_id | status       |
+---------+----------------+--------------+
|       1 |              1 | DISCONNECTED |
|       1 |              2 | CONNECTED    |
|       1 |             10 | CONNECTED    |
|       1 |             20 | CONNECTED    |
|       1 |             21 | CONNECTED    |
|       2 |              1 | CONNECTED    |
|       2 |              2 | DISCONNECTED |
|       2 |             10 | CONNECTED    |
|       2 |             20 | CONNECTED    |
|       2 |             21 | CONNECTED    |
+---------+----------------+--------------+
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the command `2 STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    ->   FROM ndbinfo.transporters;
+---------+----------------+--------------+
| node_id | remote_node_id | status       |
+---------+----------------+--------------+
|       1 |              1 | DISCONNECTED |
|       1 |              2 | CONNECTING   |
|       1 |             10 | CONNECTED    |
|       1 |             20 | CONNECTED    |
|       1 |             21 | CONNECTED    |
```

```
+---------+----------------+---------------+
5 rows in set (0.02 sec)
```

17.5.11 MySQL Cluster Security Issues

This section discusses security considerations to take into account when setting up and running MySQL Cluster.

Topics covered in this section include the following:

• MySQL Cluster and network security issues

• Configuration issues relating to running MySQL Cluster securely

• MySQL Cluster and the MySQL privilege system

• MySQL standard security procedures as applicable to MySQL Cluster

17.5.11.1 MySQL Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to MySQL Cluster. It is extremely important to remember that MySQL Cluster "out of the box" is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to a MySQL Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

• SQL or API nodes using "free slots" created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

  This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See Section 17.5.11.2, "MySQL Cluster and MySQL Privileges", for more information about this and related issues.)

> **Note**
>
> You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.
>
> More information is available elsewhere in this chapter about the `HostName` parameter. Also see Section 17.3.1, "Quick Test Setup of MySQL Cluster", for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

  This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

   We show an example of a MySQL Cluster setup using such a physically segregated network here:

   Figure 17.10 MySQL Cluster with Hardware Firewall
   This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

   This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside —without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

   > **Important**
   >
   > With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 6.1.3, "Making MySQL Secure Against Attackers", for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for MySQL Cluster is illustrated here:

Figure 17.11 MySQL Cluster with Software Firewalls
Using this type of network setup means that there are two zones of MySQL Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

Type of Node to be Accessed	Traffic to Permit
SQL or API node	• It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from within the network in which the cluster resides and is on the port that your application is using.
Data node or Management node	• It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from the IP address of an SQL or API node.

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement a MySQL Cluster network setup of this type, or of a "mixed" type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of a MySQL Cluster using hardware and software firewalls in combination is shown here:

Figure 17.12 MySQL Cluster with a Combination of Hardware and Software Firewalls
In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because MySQL Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

Note

If you wish to administer a MySQL Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure

> login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.
>
> Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

17.5.11.2 MySQL Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to MySQL Cluster and the implications of this for keeping a MySQL Cluster secure.

Standard MySQL privileges apply to MySQL Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on `NDB` tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not duplicated or shared among MySQL servers acting as SQL nodes in a MySQL Cluster. By way of example, suppose that two SQL nodes **A** and **B** are connected to the same MySQL Cluster, which has an `NDB` table named `mytable` in a database named `mydb`, and that you execute an SQL statement on server **A** that creates a new user `jon@localhost` and grants this user the `SELECT` privilege on that table:

```
mysql> GRANT SELECT ON mydb.mytable
    ->    TO jon@localhost IDENTIFIED BY 'mypass';
```

This user is *not* created on server **B**. For this to take place, the statement must also be run on server **B**. Similarly, statements run on server **A** and affecting the privileges of existing users on server **A** do not affect users on server **B** unless those statements are actually run on server **B** as well.

In other words, *changes in users and their privileges do not automatically propagate between SQL nodes by default*. Prior to MySQL Cluster NDB 7.2, any synchronization of privileges between SQL nodes must be done either manually or by scripting an application that periodically synchronizes the privilege tables on all SQL nodes in the cluster. In MySQL Cluster NDB 7.2 and later, you can enable automatic distribution of MySQL users and privileges across MySQL Cluster SQL nodes; see Section 17.5.14, "Distributed MySQL Privileges for MySQL Cluster", for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for `NDB` tables on one SQL node from users that have privileges on another SQL node. (This is true even if you are not using the automatic distribution of user privileges available in MySQl Cluster NDB 7.2 and later.) The most far-reaching example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the MySQL Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the MySQL Cluster.

- There is no firewall, or the firewall fails to protect against access to the MySQL Cluster from hosts external to the network.

- The host name or IP address of the MySQL Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster --ndb-connectstring=`*`management_host`* and access this MySQL Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute a `SHOW DATABASES` statement to obtain a list of all `NDB` databases

- Execute a `SHOW TABLES FROM` *`some_database`* statement to obtain a list of all `NDB` tables in a given database

- Run any legal MySQL statements on any of those tables, such as:

  - `SELECT * FROM` *`some_table`* to read all the data from any table

  - `DELETE FROM` *`some_table`* to delete all the data from a table

  - `DESCRIBE` *`some_table`* or `SHOW CREATE TABLE` *`some_table`* to determine the table schema

  - `UPDATE` *`some_table`* `SET` *`column1`* `=` *`some_value`* to fill a table column with "garbage" data; this could actually cause much greater damage than simply deleting all the data

    More insidious variations might include statements like these:

    ```
    UPDATE some_table SET an_int_column = an_int_column + 1
    ```

    or

    ```
    UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
    ```

    Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than `NDB`, and so not visible to a "rogue" SQL node.

> **Note**
>
> A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the `root` accounts on different cluster SQL nodes (unless you are using distributed privileges as supported in MySQL Cluster NDB 7.2 and later).

In sum, you cannot have a safe MySQL Cluster if it is directly accessible from outside your local network.

> **Important**
>
> *Never leave the MySQL root account password empty.* This is just as true when running MySQL as a MySQL Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL

> installation process before configuring the MySQL Server as an SQL node in a MySQL Cluster.

Prior to MySQL Cluster NDB 7.2, you should never convert the system tables in the `mysql` database to use the `NDB` storage engine. There are a number of reasons why you should not do this, but the most important reason is this: *Many of the SQL statements that affect `mysql` tables storing information about user privileges, stored routines, scheduled events, and other database objects cease to function if these tables are changed to use any storage engine other than `MyISAM`.* This is a consequence of various MySQL Server internals. Beginning with MySQL Cluster NDB 7.2, you can use a stored procedure provided for this purpose (see Section 17.5.14, "Distributed MySQL Privileges for MySQL Cluster"), but you are strongly advised not to attempt convert the system tables manually.

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

Summary. The two most important points to remember regarding the MySQL privilege system with regard to MySQL Cluster are:

1. **Prior to MySQL Cluster NDB 7.2.** Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

   In MySQL Cluster NDB 7.2 and later. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the MySQL Cluster distribution.

2. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in a MySQL Cluster, that user can "see" any data in that table regardless of the SQL node from which the data originated. (This is true even if you are not using the privilege distribution support available in MySQl Cluster NDB 7.2 or later.)

17.5.11.3 MySQL Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running MySQL Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of a MySQL Cluster. First and foremost, you should always run a MySQL Server as the `mysql` system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the system user `mysql` by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root     10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 \
  /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql    10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 \
  /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
  --datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
  --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
  --log-error=/usr/local/mysql/var/mothra.err
jon      10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned

by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

> **Important**
>
> Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see Section 17.5.11.2, "MySQL Cluster and MySQL Privileges"), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root

mysql> UPDATE mysql.user
    ->     SET Password=PASSWORD('secure_password')
    ->     WHERE User='root';

mysql> DELETE FROM mysql.user
    ->     WHERE User='';

mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

> **Note**
>
> Many of the MySQL Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.
>
> See Section 17.4, "MySQL Cluster Programs", for more information about these utilities.

17.5.12 MySQL Cluster Disk Data Tables

Beginning with MySQL 5.1.6, it is possible to store the nonindexed columns of `NDB` tables on disk, rather than in RAM as with previous versions of MySQL Cluster.

As part of implementing MySQL Cluster Disk Data work, a number of improvements were made in MySQL Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a "no-steal" algorithm for synchronizing a starting node with very large data sets. For more information, see the paper *Recovery Principles of MySQL Cluster 5.1*, by MySQL Cluster developers Mikael Ronström and Jonas Oreland.

MySQL Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see *MySQL Cluster Disk Data configuration parameters* and *MySQL Cluster Disk Data storage and* `GCP Stop` *errors*

The performance of a MySQL Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see Section 17.5.12.2, "Using Symbolic Links with Disk Data Objects".

17.5.12.1 MySQL Cluster Disk Data Objects

MySQL Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- *Tablespaces* act as containers for other Disk Data objects.

- *Undo log files* undo information required for rolling back transactions.

- One or more undo log files are assigned to a *log file group*, which is then assigned to a tablespace.

- *Data files* store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the MySQL Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

MySQL Cluster tablespaces and log file groups are not implemented as files.

> **Important**
>
> Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up a MySQL Cluster with all nodes (including management and SQL nodes) running MySQL 5.1.6 or newer, the basic steps for creating a Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).

   > **Note**
   >
   > In MySQL 5.1 and later, undo log files are necessary only for Disk Data tables. They are no longer used for `NDBCLUSTER` tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.

3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_1.log'
    INITIAL_SIZE 16M
    UNDO_BUFFER_SIZE 2M
    ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_2.log'
    INITIAL_SIZE 12M
    ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We use it merely to make the log files easily recognizable.

- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` clause. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the permitted values for this clause are `NDBCLUSTER` and `NDB`.

    > **Important**
    >
    > In MySQL 5.1.8 and later, there can exist only one log file group in the same MySQL Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.

- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.

- For more information about the `CREATE LOGFILE GROUP` statement, see Section 13.1.14, "CREATE LOGFILE GROUP Syntax". For more information about `ALTER LOGFILE GROUP`, see Section 13.1.3, "ALTER LOGFILE GROUP Syntax".

2. Now we can create a tablespace, which contains files to be used by MySQL Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

    Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
    ADD DATAFILE 'data_1.dat'
    USE LOGFILE GROUP lg_1
    INITIAL_SIZE 32M
    ENGINE NDBCLUSTER;
```

```
ALTER TABLESPACE ts_1
    ADD DATAFILE 'data_2.dat'
    INITIAL_SIZE 48M
    ENGINE NDBCLUSTER;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.

- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.

- All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the only permitted values for this clause are `NDBCLUSTER` and `NDB`.

- For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see Section 13.1.18, "CREATE TABLESPACE Syntax", and Section 13.1.8, "ALTER TABLESPACE Syntax".

3. Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
    member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    last_name VARCHAR(50) NOT NULL,
    first_name VARCHAR(50) NOT NULL,
    dob DATE NOT NULL,
    joined DATE NOT NULL,
    INDEX(last_name, first_name)
    )
    TABLESPACE ts_1 STORAGE DISK
    ENGINE NDBCLUSTER;
```

The `TABLESPACE ... STORAGE DISK` option tells the `NDBCLUSTER` storage engine to use tablespace `ts_1` for disk data storage.

> **Note**
>
> Beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2, it is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See Section 13.1.17, "CREATE TABLE Syntax", for more information.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

For table `dt_1` as it has been defined here, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

Performance note.   The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see Section 17.5.12.2, "Using Symbolic Links with Disk Data Objects", for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

* A log file group cannot be dropped as long as any tablespaces are using it.

* A tablespace cannot be dropped as long as it contains any data files.

* You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.

* Beginning with MySQL 5.1.12, it is no longer possible to drop files created in association with a different tablespace than the one with which the files were created. (Bug #20053)

For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_2.dat'
    -> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_1.dat'
    -> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
    -> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
    -> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ...  DROP DATAFILE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra "`NULL` row" was added to this table in MySQL 5.1.14 for providing additional information about undo log files. For more information and examples of use, see Section 20.26.1, "The INFORMATION_SCHEMA FILES Table".

Beginning with MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8, it is also possible to view information about allocated and free disk space for each Disk Data table or table partition using the `ndb_desc` utility. For more information, see Section 17.4.10, "`ndb_desc` — Describe NDB Tables".

17.5.12.2 Using Symbolic Links with Disk Data Objects

The performance of a MySQL Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. Previous to MySQL Cluster NDB 6.2.17, MySQL Cluster NDB 6.3.22, and MySQL Cluster NDB 6.4.3, there was no direct support for this in MySQL Cluster, but it was possible to achieve this separation using symbolic links as described in this section.

Beginning with MySQL Cluster NDB 6.2.17, MySQL Cluster NDB 6.3.22, and MySQL Cluster NDB 6.4.3, the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles` make the use of symbolic links for this purpose unnecessary. For information about these parameters, see Disk Data file system parameters.

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndbd default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

> **Note**
>
> In this example, we assume that the cluster's data node hosts are all using Linux operating systems. For other platforms, you may need to substitute you operating system's commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

```
shell> cd /data0/ndb_2_fs
shell> ls
D1  D10  D11  D2  D8  D9  LCP
shell> ln -s /data0 dnlogs
shell> ln -s /data1 dndata
```

You should now have two symbolic links:

```
shell> ls -l --hide=D*
lrwxrwxrwx 1 user group   30 2007-03-19 13:58 dndata -> /data1
lrwxrwxrwx 1 user group   30 2007-03-19 13:59 dnlogs -> /data2
```

We show this only for the data node with node ID 2; however, you must do this for *each* data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
    ->    ADD UNDOFILE 'dnlogs/undo1.log'
    ->    INITIAL_SIZE 150M
```

```
        ->     UNDO_BUFFER_SIZE = 1M
        ->     ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
    ->     ADD DATAFILE 'dndata/data1.log'
    ->     USE LOGFILE GROUP lg1
    ->     INITIAL_SIZE 1G
    ->     ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls -l
total 2099304
-rw-rw-r--  1 user group 157286400 2007-03-19 14:02 undo1.dat

shell> cd /data2
shell> ls -l
total 2099304
-rw-rw-r--  1 user group 1073741824 2007-03-19 14:02 data1.dat
```

- If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node file system. Suppose you are using `/data0` for both data node file systems, but you wish to have the Disk Data files for both nodes on `/data1`. In this case, you can do something similar to what is shown here:

```
shell> cd /data0
shell> ln -s /data1/dn2 ndb_2_fs/dd
shell> ln -s /data1/dn3 ndb_3_fs/dd
shell> ls -l --hide=D* ndb_2_fs
lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn3
```

- Now you can create a logfile group and tablespace using the symbolic link, like this:

```
mysql> CREATE LOGFILE GROUP lg1
    ->     ADD UNDOFILE 'dd/undo1.log'
    ->     INITIAL_SIZE 150M
    ->     UNDO_BUFFER_SIZE = 1M
    ->     ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
    ->     ADD DATAFILE 'dd/data1.log'
    ->     USE LOGFILE GROUP lg1
    ->     INITIAL_SIZE 1G
    ->     ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls
dn2        dn3
shell> ls dn2
undo1.log        data1.log
shell> ls dn3
undo1.log        data1.log
```

17.5.12.3 MySQL Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

  For general information about calculating these values, see Section 11.7, "Data Type Storage Requirements".

  You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see Section 20.26.1, "The INFORMATION_SCHEMA FILES Table".

  > **Note**
  >
  > The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.

- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

  > **Important**
  >
  > Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

17.5.13 Adding MySQL Cluster Data Nodes Online

This section describes how to add MySQL Cluster data nodes "online"—that is, without needing to shut down the cluster completely and restart it as part of the process. This capability is available in MySQL Cluster NDB 7.0 (beginning with MySQL Cluster NDB 6.4.0) and later MySQL Cluster release series.

> **Important**
>
> Currently, you must add new data nodes to a MySQL Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

17.5.13.1 Adding MySQL Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding MySQL Cluster nodes online.

Redistribution of Data. The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently

include unique indexes (only ordered indexes are redistributed). Prior to MySQL Cluster NDB 7.0.40 and MySQL Cluster NDB 7.1.28, `BLOB` table data is also not redistributed using this method (Bug #13714148).

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using MySQL Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

Failure occurs during:	Failure occurs in:		
	"Old" data nodes	**"New" data nodes**	**System**

Node group creation	• **If a node other than the master fails:** The creation of the node group is always rolled forward.
	
	• **If the master fails:**
	
	  • **If the internal commit point has been reached:** The creation of the node group is rolled forward.
	
	  • **If the internal commit point has not yet been reached.** The creation of the node group is rolled back
		• **If a node other than the master fails:** The creation of the node group is always rolled forward.
		
		• **If the master fails:**
		
		  • **If the internal commit point has been reached:** The creation of the node group is rolled forward.
		
		  • **If the internal commit point has not yet been reached.** The creation of the node group is rolled back
			• **If the execution of CREATE NODEGROUP has reached the internal commit point:** When restarted, the cluster includes the new node group. Otherwise it without.
			
			• **If the execution of CREATE NODEGROUP has not yet reached the internal commit point:** When restarted, the cluster does not include the new node group.

Table reorganization	• **If a node other than the master fails:** The table reorganization is always rolled forward. • **If the master fails:**	• **If a node other than the master fails:** The table reorganization is always rolled forward. • **If the master fails:**	• **If the execution of an ALTER ONLINE TABLE table REORGANIZE PARTITION statement has reached the internal commit**

Failure occurs during:	Failure occurs in:		
	"Old" data nodes	**"New" data nodes**	**System**
	• **If the internal commit point has been reached:** The table reorganization is rolled forward. • **If the internal commit point has not yet been reached.** The table reorganization is rolled back.	• **If the internal commit point has been reached:** The table reorganization is rolled forward. • **If the internal commit point has not yet been reached.** The table reorganization is rolled back.	**point:** When the cluster is restarted, the data and indexes belonging to *table* are distributed using the "new" data nodes. • **If the execution of an ALTER ONLINE TABLE table REORGANIZE PARTITION statement has not yet reached the internal commit point:** When the cluster is restarted, the data and indexes belonging to *table* are distributed using only the "old" data nodes.

Dropping node groups. The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to "empty" a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.

2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

   `TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

17.5.13.2 Adding MySQL Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to a MySQL Cluster. For a detailed example, see Section 17.5.13.3, "Adding MySQL Cluster Data Nodes Online: Detailed Example".

> **Note**
>
> Beginning with MySQL Cluster NDB 7.0.4, this procedure applies whether you are using `ndbd` or `ndbmtd` binaries for the data node processes. Previously, this did not work with multi-threaded data nodes. (Bug #43108)

Assuming that you already have a running MySQL Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

   You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically

allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to "migrate", as described later in this procedure.

2. Perform a rolling restart of all MySQL Cluster management servers.

> **Important**
>
> All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing MySQL Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

   If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the MySQL Cluster.

5. Start the new data nodes.

   The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the MySQL Cluster management client to create the new node group or node groups to which the new data nodes will belong.

7. Redistribute the cluster's data among all data nodes (including the new ones) by issuing an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

> **Note**
>
> This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized using `ALTER ONLINE TABLE tbl REORGANIZE PARTITION`.

8. Reclaim the space freed on the "old" nodes by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster. Prior to MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, when adding multiple new node groups to a MySQL Cluster, it was necessary to add only the nodes to be assigned to a given new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. (Bug #54497)

17.5.13.3 Adding MySQL Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new MySQL Cluster data nodes online, starting with a MySQL Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration.   For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

> **Note**
>
> We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @192.168.0.1  (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2    @192.168.0.2  (5.1.77-ndb-7.1.37, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @192.168.0.10  (5.1.77-ndb-7.1.37)

[mysqld(API)]   2 node(s)
id=20   @192.168.0.20  (5.1.77-ndb-7.1.37)
id=21   @192.168.0.21  (5.1.77-ndb-7.1.37)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    country_code CHAR(2) NOT NULL,
    type CHAR(4) NOT NULL,
```

```
    ip_address varchar(15) NOT NULL,
    addresses BIGINT UNSIGNED DEFAULT NULL,
    date BIGINT UNSIGNED DEFAULT NULL
)   ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

> **Note**
>
> In this example, we show the single-threaded `ndbd` being used for the data node processes. However—beginning with MySQL Cluster NDB 7.0.4—you can also apply this example, if you are using the multi-threaded `ndbmtd` by substituting `ndbmtd` for `ndbd` wherever it appears in the steps that follow. (Bug #43108)

Step 1: Update configuration file.   Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 192.168.0.3 and 192.168.0.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3

[ndbd]
Id = 4
HostName = 192.168.0.4

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Once you have made the necessary changes, save the file.

Step 2: Restart the management server.   Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown

shell>
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO     -- NDB Cluster Management Server. 5.1.77-ndb-7.1.37
2008-12-08 17:29:23 [MgmSrvr] INFO     -- Reading cluster configuration from 'config.ini'
```

If you check the output of SHOW in the management client after restarting the ndb_mgm process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @192.168.0.1  (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2    @192.168.0.2  (5.1.77-ndb-7.1.37, Nodegroup: 0)
id=3 (not connected, accepting connect from 192.168.0.3)
id=4 (not connected, accepting connect from 192.168.0.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @192.168.0.10  (5.1.77-ndb-7.1.37)

[mysqld(API)]   2 node(s)
id=20   @192.168.0.20  (5.1.77-ndb-7.1.37)
id=21   @192.168.0.21  (5.1.77-ndb-7.1.37)
```

Step 3: Perform a rolling restart of the existing data nodes.   This step can be accomplished entirely within the cluster management client using the RESTART command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.1.37)
Node 1: Started (version 7.1.37)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 7.1.37)

ndb_mgm> Node 2: Started (version 7.1.37)
```

Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` *before* proceeding any further.

Beginning with MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13, you can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

Step 4: Perform a rolling restart of all cluster API nodes.   Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=192.168.0.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

Step 5: Perform an initial start of the new data nodes.   From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 192.168.0.10 --initial
```

Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @192.168.0.1  (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2    @192.168.0.2  (5.1.77-ndb-7.1.37, Nodegroup: 0)
id=3    @192.168.0.3  (5.1.77-ndb-7.1.37, no nodegroup)
id=4    @192.168.0.4  (5.1.77-ndb-7.1.37, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @192.168.0.10  (5.1.77-ndb-7.1.37)

[mysqld(API)]   2 node(s)
id=20   @192.168.0.20  (5.1.77-ndb-7.1.37)
id=21   @192.168.0.21  (5.1.77-ndb-7.1.37)
```

Step 6: Create a new node group.   You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @192.168.0.1  (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2    @192.168.0.2  (5.1.77-ndb-7.1.37, Nodegroup: 0)
id=3    @192.168.0.3  (5.1.77-ndb-7.1.37, Nodegroup: 1)
id=4    @192.168.0.4  (5.1.77-ndb-7.1.37, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @192.168.0.10  (5.1.77-ndb-7.1.37)

[mysqld(API)]    2 node(s)
id=20   @192.168.0.20  (5.1.77-ndb-7.1.37)
id=21   @192.168.0.21  (5.1.77-ndb-7.1.37)
```

Step 7: Redistribute cluster data.   When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
```

```
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition    Row count    Commit count   Frag fixed memory    Frag varsized memory
0            26086        26086          1572864              557056
1            26329        26329          1605632              557056

NDBT_ProgramExit: 0 - OK
```

You can cause the data to be redistributed among all of the data nodes by performing, for each NDBCLUSTER table, an ALTER ONLINE TABLE ... REORGANIZE PARTITION statement in the mysql client. After issuing the statement ALTER ONLINE TABLE ips REORGANIZE PARTITION, you can see using ndb_desc that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 16777217
Fragment type: 9
K Value: 6
Min load factor: 78

3            13093        13093          819200               294912

NDBT_ProgramExit: 0 - OK
```

> **Note**
>
> Normally, `ALTER [ONLINE] TABLE` *`table_name`* `REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new MySQL Cluster node group is an exception in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.
>
> Prior to MySQL Cluster NDB 6.4.3, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` with no *`partition_names`* `INTO (`*`partition_definitions`*`)` option did not work correctly with Disk Data tables or with in-memory `NDBCLUSTER` tables having one or more disk-based columns. (Bug #42549)
>
> For more information, see Section 13.1.7, "ALTER TABLE Syntax".

In addition, for each table, the `ALTER ONLINE TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
    FROM INFORMATION_SCHEMA.TABLES
    WHERE ENGINE = 'NDBCLUSTER';
```

> **Note**
>
> The `INFORMATION_SCHEMA.TABLES.ENGINE` value for a MySQL Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

> **Note**
>
> Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior to* the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER ONLINE TABLE ... REORGANIZE PARTITION`.

Alternative procedure, without rolling restart.   It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3
Nodegroup = 65536    # MySQL Cluster NDB 7.0.24 and later;
                     # MySQL Cluster NDB 7.1.13 and later

[ndbd]
Id = 4
HostName = 192.168.0.4
Nodegroup = 65536    # MySQL Cluster NDB 7.0.24 and later;
                     # MySQL Cluster NDB 7.1.13 and later

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Prior to MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13, you must perform the initial start of the cluster using the `--nowait-nodes` option with `ndbd` (or `ndbmtd` in MySQL Cluster NDB 7.0.4 and later) for each of the data nodes that you wish to have online immediately, so that the cluster does not wait for the remaining nodes to start:

```
shell> ndbd -c 192.168.0.10 --initial --nowait-nodes=3,4
```

Beginning with MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13, the data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case it is not necessary to start the nodes to be started immediately (nodes 1 and 2) with the `--nowait-nodes` option, so nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 192.168.0.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter (also introduced

in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13). By default, this is 15 seconds (15000 milliseconds).

> **Note**
>
> `StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

    ```
    shell> ndbd -c 192.168.0.10 --initial
    ```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

    ```
    ndb_mgm> CREATE NODEGROUP 3,4
    ```

3. In the `mysql` client, issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing MySQL Cluster tables cannot use the new nodes for data distribution until this has been done.)

17.5.14 Distributed MySQL Privileges for MySQL Cluster

MySQL Cluster NDB 7.2 introduces support for distributing MySQL users and privileges across all SQL nodes in a MySQL Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server's user privilege tables in the `mysql` database must use the `MyISAM` storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster's other SQL nodes. In MySQL Cluster NDB 7.2 and later, an SQL file `ndb_dist_priv.sql` is provided with the MySQL Cluster distribution. This file can be found in the `share/mysql` directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the *target* SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where `options` stands for any additional options needed to connect to this SQL node):

```
shell> mysql options -uroot < share/mysql/ndb_dist_priv.sql
```

Importing `ndb_dist_priv.sql` creates a number of stored routines (six stored procedures and one stored function) in the `mysql` database on the target SQL node. After connecting to the SQL node in the `mysql` client (as the MySQL `root` user), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
    ->     FROM INFORMATION_SCHEMA.ROUTINES
    ->     WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
    ->     ORDER BY ROUTINE_TYPE;
+------------------------------------------+----------------+--------------+
| ROUTINE_NAME                             | ROUTINE_SCHEMA | ROUTINE_TYPE |
+------------------------------------------+----------------+--------------+
| mysql_cluster_privileges_are_distributed | mysql          | FUNCTION     |
| mysql_cluster_backup_privileges          | mysql          | PROCEDURE    |
| mysql_cluster_move_grant_tables          | mysql          | PROCEDURE    |
```

```
| mysql_cluster_move_privileges             | mysql          | PROCEDURE     |
| mysql_cluster_restore_local_privileges    | mysql          | PROCEDURE     |
| mysql_cluster_restore_privileges          | mysql          | PROCEDURE     |
| mysql_cluster_restore_privileges_from_local | mysql        | PROCEDURE     |
+-------------------------------------------+----------------+---------------+

7 rows in set (0.01 sec)
```

The stored procedure named `mysql_cluster_move_privileges` creates backup copies of the existing privilege tables, then converts them to `NDB`.

`mysql_cluster_move_privileges` performs the backup and conversion in two steps. The first step is to call `mysql_cluster_backup_privileges`, which creates two sets of copies in the `mysql` database:

- A set of local copies that use the `MyISAM` storage engine. Their names are generated by adding the suffix `_backup` to the original privilege table names.

- A set of distributed copies that use the `NDBCLUSTER` storage engine. These tables are named by prefixing `ndb_` and appending `_backup` to the names of the original tables.

After the copies are created, `mysql_cluster_move_privileges` invokes `mysql_cluster_move_grant_tables`, which contains the `ALTER TABLE ... ENGINE = NDB` statements that convert the mysql system tables to `NDB`.

Normally, you should not invoke either `mysql_cluster_backup_privileges` or `mysql_cluster_move_grant_tables` manually; these stored procedures are intended only for use by `mysql_cluster_move_privileges`.

Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```
shell> mysqldump options -uroot \
    mysql host user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL `root` user). Invoke the stored procedure like this:

```
mysql> CALL mysql.mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `No data - zero rows fetched, selected, or processed` warnings when `mysql_cluster_move_privileges` returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function `mysql_cluster_privileges_are_distributed` as shown here:

```
mysql> SELECT CONCAT(
    ->     'Conversion ',
    ->     IF(mysql.mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'),
    ->     '.')
    ->     AS Result;
+----------------------+
| Result               |
+----------------------+
| Conversion succeeded. |
+----------------------+
1 row in set (0.00 sec)
```

`mysql_cluster_privileges_are_distributed` checks for the existence of the distributed privilege tables and returns `1` if all of the privilege tables are distributed; otherwise, it returns `0`.

You can verify that the backups have been created using a query such as this one:

```
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
    ->       WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
    ->       ORDER BY ENGINE;
+-------------------------+------------+
| TABLE_NAME              | ENGINE     |
+-------------------------+------------+
| host_backup             | MyISAM     |
| db_backup               | MyISAM     |
| columns_priv_backup     | MyISAM     |
| user_backup             | MyISAM     |
| tables_priv_backup      | MyISAM     |
| proxies_priv_backup     | MyISAM     |
| procs_priv_backup       | MyISAM     |
| ndb_user_backup         | ndbcluster |
| ndb_tables_priv_backup  | ndbcluster |
| ndb_proxies_priv_backup | ndbcluster |
| ndb_procs_priv_backup   | ndbcluster |
| ndb_host_backup         | ndbcluster |
| ndb_db_backup           | ndbcluster |
| ndb_columns_priv_backup | ndbcluster |
+-------------------------+------------+
14 rows in set (0.00 sec)
```

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.

> **Note**
>
> For clients connected to SQL nodes at the time that `mysql_cluster_move_privileges` is executed, you may need to execute `FLUSH PRIVILEGES` on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes any privileges associated with views and stored routines, even though distribution of views and stored routines themselves is not currently supported.

In the event that an SQL node becomes disconnected from the cluster while `mysql_cluster_move_privileges` is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as `DROP TABLE IF EXISTS mysql.user mysql.db mysql.tables_priv mysql.columns_priv mysql.procs_priv`. This causes the SQL node to use the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial`), the shared privilege tables are lost. If this happens, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform the restoration, you should start it with `--skip-grant-tables` when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` option.

You can also restore the distributed tables using `ndb_restore --restore-privilege-tables` from a backup made using `START BACKUP` in the `ndb_mgm` client. (The `MyISAM` tables created by `mysql_cluster_move_privileges` are not backed up by the `START BACKUP` command.) `ndb_restore` does not restore the privilege tables by default; the `--restore-privilege-tables` option causes it to do so.

You can restore the SQL node's local privileges using either of two procedures. `mysql_cluster_restore_privileges` works as follows:

1. If copies of the `mysql.ndb_*_backup` tables are available, attempt to restore the system tables from these.

2. Otherwise, attempt to restore the system tables from the local backups named `*_backup` (without the `ndb_` prefix).

The other procedure, named `mysql_cluster_restore_local_privileges`, restores the system tables from the local backups only, without checking the `ndb_*` backups.

The system tables re-created by `mysql_cluster_restore_privileges` or `mysql_cluster_restore_local_privileges` use the MySQL server default storage engine; they are not shared or distributed in any way, and do not use MySQL Cluster's `NDB` storage engine.

The additional stored procedure `mysql_cluster_restore_privileges_from_local` is intended for the use of `mysql_cluster_restore_privileges` and `mysql_cluster_restore_local_privileges`. It should not be invoked directly.

> **Important**
>
> Applications that access MySQL Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other `NDB` tables. In particular, you should keep in mind that *NDB API and ClusterJ applications can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions*.

17.5.15 NDB API Statistics Counters and Variables

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, a number of types of statistical counters relating to actions performed by or affecting `Ndb` objects are added. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by `NDBCLUSTER`. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `INFORMATION_SCHEMA.SESSION_STATUS` or `INFORMATION_SCHEMA.GLOBAL_STATUS` table. By comparing the values before and after statements operating on `NDB` tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
+-----------------------------------------+----------+
| Variable_name                           | Value    |
+-----------------------------------------+----------+
| Ndb_api_wait_exec_complete_count_session | 0       |
| Ndb_api_wait_scan_result_count_session   | 0       |
```

```
| Ndb_api_wait_meta_request_count_session      | 0        |
| Ndb_api_wait_nanos_count_session             | 0        |
| Ndb_api_bytes_sent_count_session             | 0        |
| Ndb_api_bytes_received_count_session         | 0        |
| Ndb_api_trans_start_count_session            | 0        |
| Ndb_api_trans_commit_count_session           | 0        |
| Ndb_api_trans_abort_count_session            | 0        |
| Ndb_api_trans_close_count_session            | 0        |
| Ndb_api_pk_op_count_session                  | 0        |
| Ndb_api_uk_op_count_session                  | 0        |
| Ndb_api_table_scan_count_session             | 0        |
| Ndb_api_range_scan_count_session             | 0        |
| Ndb_api_pruned_scan_count_session            | 0        |
| Ndb_api_scan_batch_count_session             | 0        |
| Ndb_api_read_row_count_session               | 0        |
| Ndb_api_trans_local_read_row_count_session   | 0        |
| Ndb_api_event_data_count_injector            | 0        |
| Ndb_api_event_nondata_count_injector         | 0        |
| Ndb_api_event_bytes_count_injector           | 0        |
| Ndb_api_wait_exec_complete_count_slave       | 0        |
| Ndb_api_wait_scan_result_count_slave         | 0        |
| Ndb_api_wait_meta_request_count_slave        | 0        |
| Ndb_api_wait_nanos_count_slave               | 0        |
| Ndb_api_bytes_sent_count_slave               | 0        |
| Ndb_api_bytes_received_count_slave           | 0        |
| Ndb_api_trans_start_count_slave              | 0        |
| Ndb_api_trans_commit_count_slave             | 0        |
| Ndb_api_trans_abort_count_slave              | 0        |
| Ndb_api_trans_close_count_slave              | 0        |
| Ndb_api_pk_op_count_slave                    | 0        |
| Ndb_api_uk_op_count_slave                    | 0        |
| Ndb_api_table_scan_count_slave               | 0        |
| Ndb_api_range_scan_count_slave               | 0        |
| Ndb_api_pruned_scan_count_slave              | 0        |
| Ndb_api_scan_batch_count_slave               | 0        |
| Ndb_api_read_row_count_slave                 | 0        |
| Ndb_api_trans_local_read_row_count_slave     | 0        |
| Ndb_api_wait_exec_complete_count             | 2        |
| Ndb_api_wait_scan_result_count               | 3        |
| Ndb_api_wait_meta_request_count              | 27       |
| Ndb_api_wait_nanos_count                     | 45612023 |
| Ndb_api_bytes_sent_count                     | 992      |
| Ndb_api_bytes_received_count                 | 9640     |
| Ndb_api_trans_start_count                    | 2        |
| Ndb_api_trans_commit_count                   | 1        |
| Ndb_api_trans_abort_count                    | 0        |
| Ndb_api_trans_close_count                    | 2        |
| Ndb_api_pk_op_count                          | 1        |
| Ndb_api_uk_op_count                          | 0        |
| Ndb_api_table_scan_count                     | 1        |
| Ndb_api_range_scan_count                     | 0        |
| Ndb_api_pruned_scan_count                    | 0        |
| Ndb_api_scan_batch_count                     | 0        |
| Ndb_api_read_row_count                       | 1        |
| Ndb_api_trans_local_read_row_count           | 1        |
| Ndb_api_event_data_count                     | 0        |
| Ndb_api_event_nondata_count                  | 0        |
| Ndb_api_event_bytes_count                    | 0        |
+----------------------------------------------+----------+
60 rows in set (0.02 sec)
```

These status variables are also available from the SESSION_STATUS and GLOBAL_STATUS tables of the INFORMATION_SCHEMA database, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
    ->     WHERE VARIABLE_NAME LIKE 'ndb_api%';
```

```
+--------------------------------------------+----------------+
| VARIABLE_NAME                              | VARIABLE_VALUE |
+--------------------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT_SESSION   | 2              |
| NDB_API_WAIT_SCAN_RESULT_COUNT_SESSION     | 0              |
| NDB_API_WAIT_META_REQUEST_COUNT_SESSION    | 1              |
| NDB_API_WAIT_NANOS_COUNT_SESSION           | 8144375        |
| NDB_API_BYTES_SENT_COUNT_SESSION           | 68             |
| NDB_API_BYTES_RECEIVED_COUNT_SESSION       | 84             |
| NDB_API_TRANS_START_COUNT_SESSION          | 1              |
| NDB_API_TRANS_COMMIT_COUNT_SESSION         | 1              |
| NDB_API_TRANS_ABORT_COUNT_SESSION          | 0              |
| NDB_API_TRANS_CLOSE_COUNT_SESSION          | 1              |

```

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multi-threaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the `mysql` client*. This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `SESSION_STATUS` or the `GLOBAL_STATUS` table.

- *Session counters (session specific)*

  Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

  In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "`_session` variables", with a leading underscore.

- *Slave counters (global)*

  This set of counters relates to the `Ndb` objects used by the replication slave SQL thread, if any. If this `mysqld` does not act as a replication slave, or does not use `NDB` tables, then all of these counts are 0.

  We refer to the related status variables as "`_slave` variables" (with a leading underscore).

- *Injector counters (global)*

  Injector counters relate to the `Ndb` object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, `mysqld` processes attached to a MySQL Cluster continue to listen for some events, such as schema changes.

  We refer to the status variables that correspond to NDB API injector counters as "`_injector` variables" (with a leading underscore).

- *Server (Global) counters (global)*

  This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the slave SQL thread (if any), the binlog injector, and the `NDB` utility thread.

  We refer to the status variables that correspond to these counters as "global variables" or "`mysqld`-level variables".

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
+-----------------------------------------+---------+
| Variable_name                           | Value   |
+-----------------------------------------+---------+
| Ndb_api_wait_exec_complete_count_session | 2      |
| Ndb_api_wait_scan_result_count_session  | 0       |
| Ndb_api_wait_meta_request_count_session | 1       |
| Ndb_api_wait_nanos_count_session        | 8144375 |
| Ndb_api_bytes_sent_count_session        | 68      |
| Ndb_api_bytes_received_count_session    | 84      |
| Ndb_api_trans_start_count_session       | 1       |
```

```
| Ndb_api_trans_commit_count_session            | 1        |
| Ndb_api_trans_abort_count_session             | 0        |
| Ndb_api_trans_close_count_session             | 1        |
| Ndb_api_pk_op_count_session                   | 1        |
| Ndb_api_uk_op_count_session                   | 0        |
| Ndb_api_table_scan_count_session              | 0        |
| Ndb_api_range_scan_count_session              | 0        |
| Ndb_api_pruned_scan_count_session             | 0        |
| Ndb_api_scan_batch_count_session              | 0        |
| Ndb_api_read_row_count_session                | 1        |
| Ndb_api_trans_local_read_row_count_session    | 1        |
+-----------------------------------------------+----------+
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
    ->     WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+-----------------------------------+----------------+
| VARIABLE_NAME                     | VARIABLE_VALUE |
+-----------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT  | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT    | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT   | 28             |
| NDB_API_WAIT_NANOS_COUNT          | 53756398       |
| NDB_API_BYTES_SENT_COUNT          | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT      | 9724           |
| NDB_API_TRANS_START_COUNT         | 3              |
| NDB_API_TRANS_COMMIT_COUNT        | 2              |
| NDB_API_TRANS_ABORT_COUNT         | 0              |
| NDB_API_TRANS_CLOSE_COUNT         | 3              |
| NDB_API_PK_OP_COUNT               | 2              |
| NDB_API_UK_OP_COUNT               | 0              |
| NDB_API_TABLE_SCAN_COUNT          | 1              |
| NDB_API_RANGE_SCAN_COUNT          | 0              |
| NDB_API_PRUNED_SCAN_COUNT         | 0              |
| NDB_API_SCAN_BATCH_COUNT          | 0              |
| NDB_API_READ_ROW_COUNT            | 2              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2             |
| NDB_API_EVENT_DATA_COUNT          | 0              |
| NDB_API_EVENT_NONDATA_COUNT       | 0              |
| NDB_API_EVENT_BYTES_COUNT         | 0              |
+-----------------------------------+----------------+
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
+---------------------------------------+-------+
| Variable_name                         | Value |
+---------------------------------------+-------+
| Ndb_api_event_data_count_injector     | 0     |
| Ndb_api_event_nondata_count_injector  | 0     |
| Ndb_api_event_bytes_count_injector    | 0     |
| Ndb_api_event_data_count              | 0     |
| Ndb_api_event_nondata_count           | 0     |
| Ndb_api_event_bytes_count             | 0     |
+---------------------------------------+-------+
6 rows in set (0.00 sec)
```

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+------------------------------------+-------+
| Variable_name                      | Value |
+------------------------------------+-------+
| Ndb_api_event_data_count_injector    | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector   | 0     |
+------------------------------------+-------+
3 rows in set (0.00 sec)
```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

Counter Name	Description
	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
`WaitExecCompleteCount`	Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all `execute()` calls as well as implicit executes for blob operations and auto-increment not visible to clients.
	• `Ndb_api_wait_exec_complete_count_session` • `Ndb_api_wait_exec_complete_count_slave` • [none] • `Ndb_api_wait_exec_complete_count`
`WaitScanResultCount`	Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close.
	• `Ndb_api_wait_scan_result_count_session` • `Ndb_api_wait_scan_result_count_slave` • [none] • `Ndb_api_wait_scan_result_count`
`WaitMetaRequestCount`	Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).
	• `Ndb_api_wait_meta_request_count_session` • `Ndb_api_wait_meta_request_count_slave` • [none]

Counter Name	Description
	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
	• `Ndb_api_wait_meta_request_count`
`WaitNanosCount`	Total time (in nanoseconds) spent waiting for some type of signal from the data nodes.
	• `Ndb_api_wait_nanos_count_session` • `Ndb_api_wait_nanos_count_slave` • [none] • `Ndb_api_wait_nanos_count`
`BytesSentCount`	Amount of data (in bytes) sent to the data nodes
	• `Ndb_api_bytes_sent_count_session` • `Ndb_api_bytes_sent_count_slave` • [none] • `Ndb_api_bytes_sent_count`
`BytesRecvdCount`	Amount of data (in bytes) received from the data nodes
	• `Ndb_api_bytes_received_count_session` • `Ndb_api_bytes_received_count_slave` • [none] • `Ndb_api_bytes_received_count`
`TransStartCount`	Number of transactions started.
	• `Ndb_api_trans_start_count_session` • `Ndb_api_trans_start_count_slave` • [none] • `Ndb_api_trans_start_count`
`TransCommitCount`	Number of transactions committed.
	• `Ndb_api_trans_commit_count_session` • `Ndb_api_trans_commit_count_slave` • [none] • `Ndb_api_trans_commit_count`

Counter Name	Description
	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
TransAbortCount	Number of transactions aborted.
	• Ndb_api_trans_abort_count_session • Ndb_api_trans_abort_count_slave • [none] • Ndb_api_trans_abort_count
TransCloseCount	Number of transactions aborted. (This value may be greater than the sum of TransCommitCount and TransAbortCount.)
	• Ndb_api_trans_close_count_session • Ndb_api_trans_close_count_slave • [none] • Ndb_api_trans_close_count
PkOpCount	Number of operations based on or using primary keys. This count includes blob-part table operations, implicit unlocking operations, and auto-increment operations, as well as primary key operations normally visible to MySQL clients.
	• Ndb_api_pk_op_count_session • Ndb_api_pk_op_count_slave • [none] • Ndb_api_pk_op_count
UkOpCount	Number of operations based on or using unique keys.
	• Ndb_api_uk_op_count_session • Ndb_api_uk_op_count_slave • [none] • Ndb_api_uk_op_count
TableScanCount	Number of table scans that have been started. This includes scans of internal tables.
	• Ndb_api_table_scan_count_session • Ndb_api_table_scan_count_slave

Counter Name	Description
Counter Name	**Description**
	Status Variables (by statistic type):
	• **Session**
	• **Slave**
	• **Injector**
	• **Server**
	• [none]
	• Ndb_api_table_scan_count
RangeScanCount	Number of range scans that have been started.
	• Ndb_api_range_scan_count_session
	• Ndb_api_range_scan_count_slave
	• [none]
	• Ndb_api_range_scan_count
PrunedScanCount	Number of scans that have been pruned to a single partition.
	• Ndb_api_pruned_scan_count_session
	• Ndb_api_pruned_scan_count_slave
	• [none]
	• Ndb_api_pruned_scan_count
ScanBatchCount	Number of batches of rows received. (A *batch* in this context is a set of scan results from a single fragment.)
	• Ndb_api_scan_batch_count_session
	• Ndb_api_scan_batch_count_slave
	• [none]
	• Ndb_api_scan_batch_count
ReadRowCount	Total number of rows that have been read. Includes rows read using primary key, unique key, and scan operations.
	• Ndb_api_read_row_count_session
	• Ndb_api_read_row_count_slave
	• [none]
	• Ndb_api_read_row_count
TransLocalReadRowCount	Number of rows read from the data same node on which the transaction was being run.
	• Ndb_api_trans_local_read_row_count_session
	• Ndb_api_trans_local_read_row_count_slave

Counter Name	Description
	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
	• [none] • Ndb_api_trans_local_read_row_count
DataEventsRecvdCount	Number of row change events received.
	• [none] • [none] • Ndb_api_event_data_count_injector • Ndb_api_event_data_count
NondataEventsRecvdCount	Number of events received, other than row change events.
	• [none] • [none] • Ndb_api_event_nondata_count_injector • Ndb_api_event_nondata_count
EventBytesRecvdCount	Number of bytes of events received.
	• [none] • [none] • Ndb_api_event_bytes_count_injector • Ndb_api_event_bytes_count

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+----------------------------------+-------+
| Variable_name                    | Value |
+----------------------------------+-------+
| Ndb_api_trans_commit_count_session | 1   |
| Ndb_api_trans_commit_count_slave   | 0   |
| Ndb_api_trans_commit_count         | 2   |
+----------------------------------+-------+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an `NDB` table, named `t`, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-------------------------------------------+--------+
| Variable_name                             | Value  |
+-------------------------------------------+--------+
| Ndb_api_wait_exec_complete_count_session  | 2      |
| Ndb_api_wait_scan_result_count_session    | 0      |
| Ndb_api_wait_meta_request_count_session   | 3      |
| Ndb_api_wait_nanos_count_session          | 820705 |
| Ndb_api_bytes_sent_count_session          | 132    |
| Ndb_api_bytes_received_count_session      | 372    |
| Ndb_api_trans_start_count_session         | 1      |
| Ndb_api_trans_commit_count_session        | 1      |
| Ndb_api_trans_abort_count_session         | 0      |
| Ndb_api_trans_close_count_session         | 1      |
| Ndb_api_pk_op_count_session               | 1      |
| Ndb_api_uk_op_count_session               | 0      |
| Ndb_api_table_scan_count_session          | 0      |
| Ndb_api_range_scan_count_session          | 0      |
| Ndb_api_pruned_scan_count_session         | 0      |
| Ndb_api_scan_batch_count_session          | 0      |
| Ndb_api_read_row_count_session            | 1      |
| Ndb_api_trans_local_read_row_count_session | 1     |
+-------------------------------------------+--------+
18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)
```

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-------------------------------------------+-----------+
| Variable_name                             | Value     |
+-------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session  | 8         |
| Ndb_api_wait_scan_result_count_session    | 0         |
| Ndb_api_wait_meta_request_count_session   | 17        |
| Ndb_api_wait_nanos_count_session          | 706871709 |
| Ndb_api_bytes_sent_count_session          | 2376      |
| Ndb_api_bytes_received_count_session      | 3844      |
| Ndb_api_trans_start_count_session         | 4         |
| Ndb_api_trans_commit_count_session        | 4         |
| Ndb_api_trans_abort_count_session         | 0         |
| Ndb_api_trans_close_count_session         | 4         |
| Ndb_api_pk_op_count_session               | 6         |
| Ndb_api_uk_op_count_session               | 0         |
| Ndb_api_table_scan_count_session          | 0         |
| Ndb_api_range_scan_count_session          | 0         |
| Ndb_api_pruned_scan_count_session         | 0         |
| Ndb_api_scan_batch_count_session          | 0         |
| Ndb_api_read_row_count_session            | 2         |
| Ndb_api_trans_local_read_row_count_session | 1        |
+-------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`: Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+------------------------------------------+-----------+
| Variable_name                            | Value     |
+------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session | 11        |
| Ndb_api_wait_scan_result_count_session   | 6         |
| Ndb_api_wait_meta_request_count_session  | 20        |
| Ndb_api_wait_nanos_count_session         | 707370418 |
| Ndb_api_bytes_sent_count_session         | 2724      |
| Ndb_api_bytes_received_count_session     | 4116      |
| Ndb_api_trans_start_count_session        | 7         |
| Ndb_api_trans_commit_count_session       | 6         |
| Ndb_api_trans_abort_count_session        | 0         |
| Ndb_api_trans_close_count_session        | 7         |
| Ndb_api_pk_op_count_session              | 8         |
| Ndb_api_uk_op_count_session              | 0         |
| Ndb_api_table_scan_count_session         | 1         |
| Ndb_api_range_scan_count_session         | 0         |
| Ndb_api_pruned_scan_count_session        | 0         |
| Ndb_api_scan_batch_count_session         | 0         |
| Ndb_api_read_row_count_session           | 3         |
| Ndb_api_trans_local_read_row_count_session | 2       |
+------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the "before" and "after" values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the `NDB` storage engine.

- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` (707370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

  On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

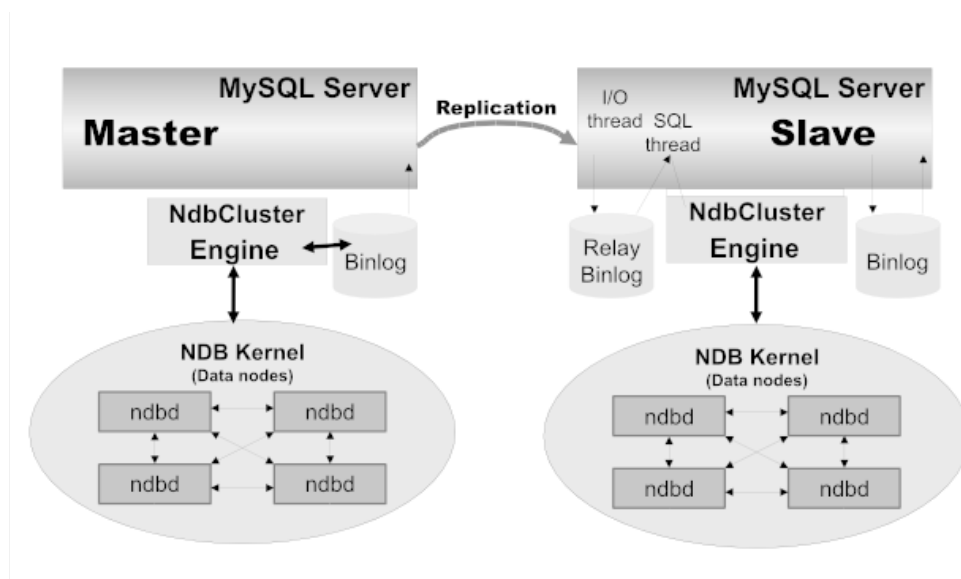
- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

17.6 MySQL Cluster Replication

Previous to MySQL 5.1.6, *asynchronous replication*, more usually referred to simply as "replication", was not available when using MySQL Cluster. MySQL 5.1.6 introduces master-slave replication of this type for MySQL Cluster databases. This section explains how to set up and manage a configuration wherein one group of computers operating as a MySQL Cluster replicates to a second computer or group of computers.

We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 16, *Replication*).

Normal (non-clustered) replication involves a "master" server and a "slave" server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although a MySQL Cluster itself depends on the NDB storage engine for clustering functionality, it is not necessary to use NDB as the storage engine for the slave's copies of the replicated tables (see Replication from NDB to other storage engines). However, for maximum availability, it is possible (and preferable) to replicate from one MySQL Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

Figure 17.13 MySQL Cluster-to-Cluster Replication Layout


In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binlog injector thread, which runs on each MySQL server and produces a binary log (`binlog`). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with MySQL Cluster and MySQL Cluster Replication, see Section 17.6.9.2, "Point-In-Time Recovery Using MySQL Cluster Replication".

NDB API _slave status variables. Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, NDB API counters provide enhanced monitoring capabilities on MySQL Cluster replication slaves. These are implelemented as NDB statistics `_slave` status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in a `mysql` client session connected to a MySQL Server that is acting as a slave in MySQL Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated NDB tables, you can observe the corresponding actions taken on the NDB API level by the slave, which can be useful when monitoring or troubleshooting MySQL Cluster Replication. Section 17.5.15, "NDB API Statistics Counters and Variables", provides additional information.

Replication from NDB to non-NDB tables. It is possible to replicate NDB tables from a MySQL Cluster acting as the master to tables using other MySQL storage engines such as InnoDB or MyISAM on a slave

`mysqld`. This is subject to a number of conditions; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

17.6.1 MySQL Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

Symbol or Abbreviation	Description (Refers to...)
`M`	The cluster serving as the (primary) replication master
`S`	The cluster acting as the (primary) replication slave
`shellM>`	Shell command to be issued on the master cluster
`mysqlM>`	MySQL client command issued on a single MySQL server running as an SQL node on the master cluster
`mysqlM*>`	MySQL client command to be issued on all SQL nodes participating in the replication master cluster
`shellS>`	Shell command to be issued on the slave cluster
`mysqlS>`	MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster
`mysqlS*>`	MySQL client command to be issued on all SQL nodes participating in the replication slave cluster
`C`	Primary replication channel
`C'`	Secondary replication channel
`M'`	Secondary replication master
`S'`	Secondary replication slave

17.6.2 General Requirements for MySQL Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of a MySQL Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be started with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in Section 17.6.6, "Starting MySQL Cluster Replication (Single Replication Channel)". For general information about row-based replication, see Section 16.1.2, "Replication Formats".

> **Important**
>
> If you attempt to use MySQL Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see Section 17.6.4, "MySQL Cluster Replication Schema and Tables"). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.
>
> In all MySQL Cluster NDB 6.x and 7.x releases, the default value for the `--binlog-format` option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all MySQL Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see Section 16.4.2, "Replication Compatibility Between MySQL Versions"). It is due to such differences between the binaries in the MySQL Cluster and MySQL Server 5.1 distributions that MySQL Cluster Replication has the additional requirement that both `mysqld` binaries come from a MySQL Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same MySQL Cluster distribution for all master and slave `mysqld` binaries.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

All `NDB` tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()`) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

> **Note**
>
> It is possible to replicate a MySQL Cluster using statement-based replication. However, in this case, the following restrictions apply:
>
> - All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.
>
> - It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
>
> - Only changes made at the SQL level are replicated.
>
> These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Section 16.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication", for more specific information concerning the differences between the two replication formats.

17.6.3 Known Issues in MySQL Cluster Replication

This section discusses known problems or issues when using replication with MySQL Cluster in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1).

Loss of master-slave connection. A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the master cluster without being recorded in the replication master's binary log.* For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with

the master. MySQL Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

Prior to MySQL 5.1.18, a MySQL Cluster replication slave `mysqld` had no way of detecting that the connection from the master had been interrupted. For this reason, it was possible for the slave to become inconsistent with the master.

Beginning with MySQL 5.1.18, the replication master issues a "gap" event when connecting or reconnecting to the master cluster. (A gap event is a type of "incident event," which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Section 17.6.8, "Implementing Failover with MySQL Cluster Replication", for more information about what to do in such circumstances.

> **Important**
>
> Because MySQL Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Section 17.6.7, "Using Two Replication Channels for MySQL Cluster Replication", and Section 17.6.8, "Implementing Failover with MySQL Cluster Replication".
>
> However, if you are replicating from a standalone MySQL server to a MySQL Cluster, one channel is usually sufficient.

Multibyte character sets.   Previously, there were several known issues with regard to the use of multibyte characters sets with MySQL Cluster Replication. These were resolved in MySQL 5.1.21, MySQL Cluster NDB 6.2.14, and MySQL Cluster NDB 6.3.11. (See Bug #27404 and Bug #29562.)

Circular replication.   Prior to MySQL 5.1.18, circular replication was not supported with MySQL Cluster replication, due to the fact that all log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the MySQL server used as master and not with the server ID of the originating server.

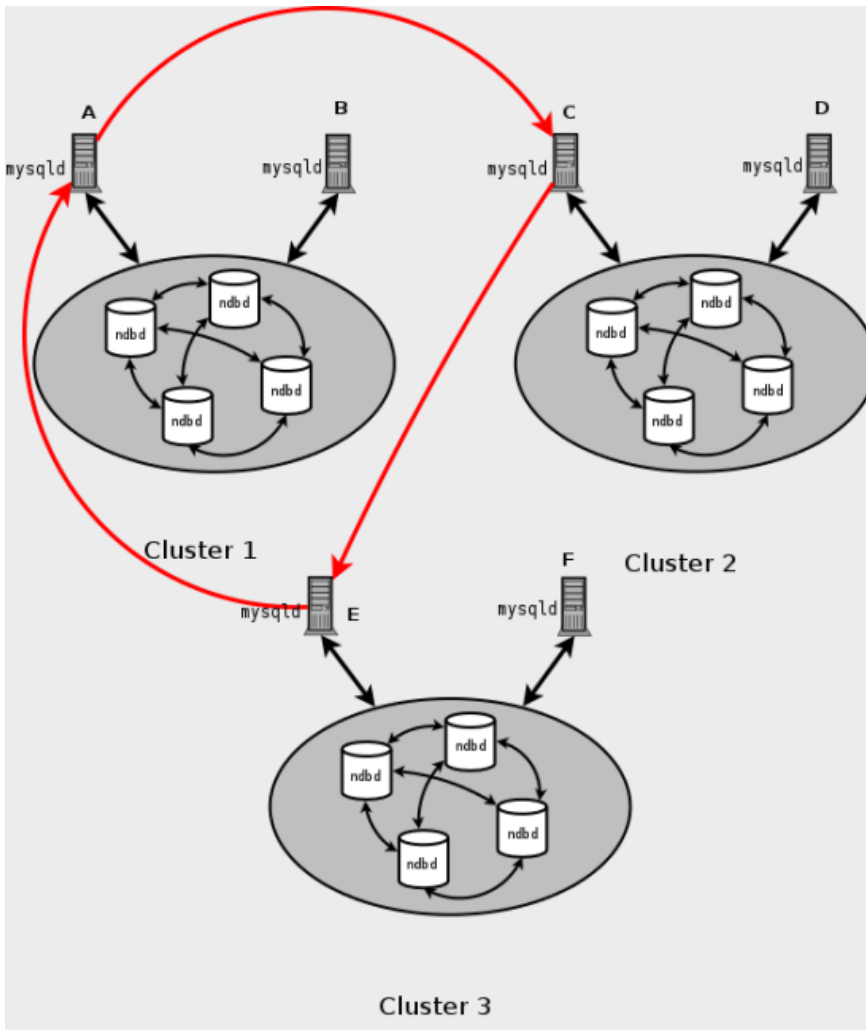
Beginning with MySQL 5.1.18, this limitation is lifted, as discussed in the next few paragraphs, in which we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same

- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

Figure 17.14 MySQL Cluster Circular Replication With All Masters As Slaves


In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:

Figure 17.15 MySQL Cluster Circular Replication Where Not All Masters Are Slaves
In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates`). This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

> **Note**
>
> Beginning with MySQL 5.1.24, the `NDB` storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of MySQL Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`, although this is not necessary in MySQL Cluster replication, since MySQL Cluster now sets this variable automatically and ignores any attempts to set it explicitly. (Bug #31609)

MySQL Cluster replication and primary keys.   In MySQL 5.1.6, only those `NDB` tables having explicit primary keys could be replicated. This limitation was lifted in MySQL 5.1.7. However, in the event of a node failure, errors in replication of `NDB` tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all `NDB` tables being replicated have primary keys.

MySQL Cluster Replication and Unique Keys.   Prior to MySQL Cluster NDB 7.0.25 and MySQL Cluster NDB 7.1.14, operations that updated values of unique key columns of `NDB` tables could result in duplicate-key errors when replicated. This was due to the ordering of row events in the binary log according to the partitioning of the base table, which meant that they could appear in a different order from that in which they were originally executed. (Bug #11756082)

In MySQL Cluster NDB 7.0.25, MySQL Cluster NDB 7.1.14, and later, this issue is solved for replication between `NDB` tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by `NDB`. Thus, updates of unique keys when replicating from `NDB` to a different storage engine such as `MyISAM` or `InnoDB` are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using `NDB` table such as `t`, is created and populated on the master (and replicated to a slave that does not support deferred unique key updates) as shown here:

```
CREATE TABLE t (
    p INT PRIMARY KEY,
    c INT,
    UNIQUE KEY u (c)
)   ENGINE NDB;

INSERT INTO t
    VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following `UPDATE` statement on `t` succeeded on the master, since the rows affected are processed in the order determined by the `ORDER BY` option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement failed with a duplicate key error or other constraint violation on the slave, because the ordering of the row updates was done for one partition at a time, rather than for the table as a whole.

> **Note**
>
> In MySQL 5.1.6 and later, every `NDB` table is implicitly partitioned by key when it is created. This also applies to all MySQL Cluster NDB 6.x and MySQL Cluster NDB 7.x releases. See Section 18.2.4, "KEY Partitioning", for more information.

Restarting with --initial.   Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from `0`. (This is generally true of MySQL Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

auto_increment_offset and auto_increment_increment variables.   The use of the `auto_increment_offset` and `auto_increment_increment` server system variables is supported beginning with MySQL 5.1.20. Previously, these produced unpredictable results when used with `NDB` tables or MySQL Cluster replication.

Replication from NDB to other storage engines.   It is possible to replicate an `NDB` table on the master to a table using a different storage engine on the slave, taking into account the restrictions listed here:

- Multi-master and circular replication are not supported (tables on both the master and the slave must use the `NDB` storage engine for this to work).

- Using a storage engine which does not perform binary logging for slave tables requires special handling.

- Use of a nontransactional storage engine for slave tables also requires special handling.

- The master `mysqld` must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

The next few paragraphs provide additional information about each of the issues just described.

Multiple masters not supported when replicating NDB to other storage engines.   For replication from `NDB` to a different storage engine, the relationship between the two databases must be a simple master-slave one. This means that circular or master-master replication is not supported between MySQL Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between `NDB` and a different storage engine. (However, a MySQL Cluster database *can* simultaneously replicate to multiple slave MySQL Cluster databases.) If the master uses `NDB` tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes; however, for the slave to change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

Replicating NDB to a slave storage engine that does not perform binary logging.   If you attempt to replicate from a MySQL Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error `1595`). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the slave.**   This can be accomplished by setting `sql_log_bin = 0`.

- **Change the storage engine used for the mysql.ndb_apply_status table.**   Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-`NDB` storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.

- **Filter out changes to the mysql.ndb_apply_status table on the slave.**   This can be done by starting the slave SQL node with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

> **⚠ Important**
>
> You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one MySQL Cluster to another. See Replication and binary log filtering rules with replication between MySQL Clusters, for details.

Replication from NDB to a nontransactional storage engine.   When replicating from `NDB` to a nontransactional storage engine such as `MyISAM`, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these in MySQL Cluster NDB 6.2 and later MySQL Cluster releases by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes (rather than as updates).

In addition, when replicating from `NDB` to a storage engine that does not implement transactions, if the slave fails to apply any row changes from a given transaction, it does not roll back the rest of the

transaction. (This is true when replicating tables using any transactional storage engine—not only `NDB`—to a nontransactional storage engine.) Because of this, it cannot be guaranteed that transactional consistency will be maintained on the slave in such cases.

Replication and binary log filtering rules with replication between MySQL Clusters.   If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between MySQL Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database *db_name* are replicated. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

   Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes *only* to tables in database *db_name* are written to the binary log. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

   Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see Section 16.1.3, "Replication and Binary Logging Options and Variables".

2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see Section 5.4.4, "The Binary Log".

If you are replicating a MySQL Cluster to a slave that uses a storage engine other than `NDB`, the considerations just given previously may not apply, as discussed elsewhere in this section.

MySQL Cluster Replication and IPv6.   Currently, the NDB API and MGM API do not support IPv6. However, beginning with MySQL Cluster NDB 6.4.1, MySQL Servers—including those acting as SQL nodes in a MySQL Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between MySQL Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:

Figure 17.16 Replication Between SQL Nodes Connected Using IPv6
However, all connections originating *within* the MySQL Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all MySQL Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

Attribute promotion and demotion.   Formerly, support in MySQL Cluster for type conversions between columns of similar but different types on the master and the slave was extremely limited. However, starting with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3, MySQL Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in MySQL Cluster, see Attribute promotion and demotion (MySQL Cluster).

17.6.4 MySQL Cluster Replication Schema and Tables

Replication in MySQL Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the `MyISAM` storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
    `Position`  BIGINT(20) UNSIGNED NOT NULL,
    `File`      VARCHAR(255) NOT NULL,
    `epoch`     BIGINT(20) UNSIGNED NOT NULL,
```

```
    `inserts`   BIGINT(20) UNSIGNED NOT NULL,
    `updates`   BIGINT(20) UNSIGNED NOT NULL,
    `deletes`   BIGINT(20) UNSIGNED NOT NULL,
    `schemaops` BIGINT(20) UNSIGNED NOT NULL,
    `next_position` bigint(20) unsigned NOT NULL,
    `next_file` varchar(255) NOT NULL,
    PRIMARY KEY (`epoch`)
) ENGINE=MYISAM  DEFAULT CHARSET=latin1;
```

The size of this table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is `OFF`, meaning that the number of entries per file depends on the length of time that the file is in use; that is,

```
[number of epochs per file] = [time spent per file] / TimeBetweenEpochs
```

A busy MySQL Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a "quiet" MySQL Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in MySQL Cluster replication setups employing multiple masters. The `SELECT` statement used to find the closest binlog position to the highest applied epoch on the slave in a multi-master setup (see Section 17.6.10, "MySQL Cluster Replication: Multi-Master and Circular Replication") employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the master has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-master failover times by adding an index to these columns, as shown here:

```
ALTER TABLE mysql.ndb_binlog_index
    ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single master to a single slave, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

The `next_position` and `next_file` columns were added in MySQL Cluster NDB 7.2.6; see Section 17.6.8, "Implementing Failover with MySQL Cluster Replication", for more information about using these columns.

> **Important**
>
> Prior to MySQL 5.1.14, the `ndb_binlog_index` table was known as `binlog_index`, and was kept in a separate `cluster` database, which in MySQL 5.1.7 and earlier was known as the `cluster_replication` database. Similarly, the `ndb_apply_status` and `ndb_schema` tables were known as `apply_status` and `schema`, and were also found in the `cluster` (earlier `cluster_replication`) database. However, beginning with MySQL 5.1.14, all MySQL Cluster replication tables reside in the `mysql` system database.
>
> Information about how this change affects upgrades from MySQL Cluster 5.1.13 and earlier to 5.1.14 and later versions can be found in http://dev.mysql.com/doc/relnotes/mysql/5.1/en/news-5-1-14.html.

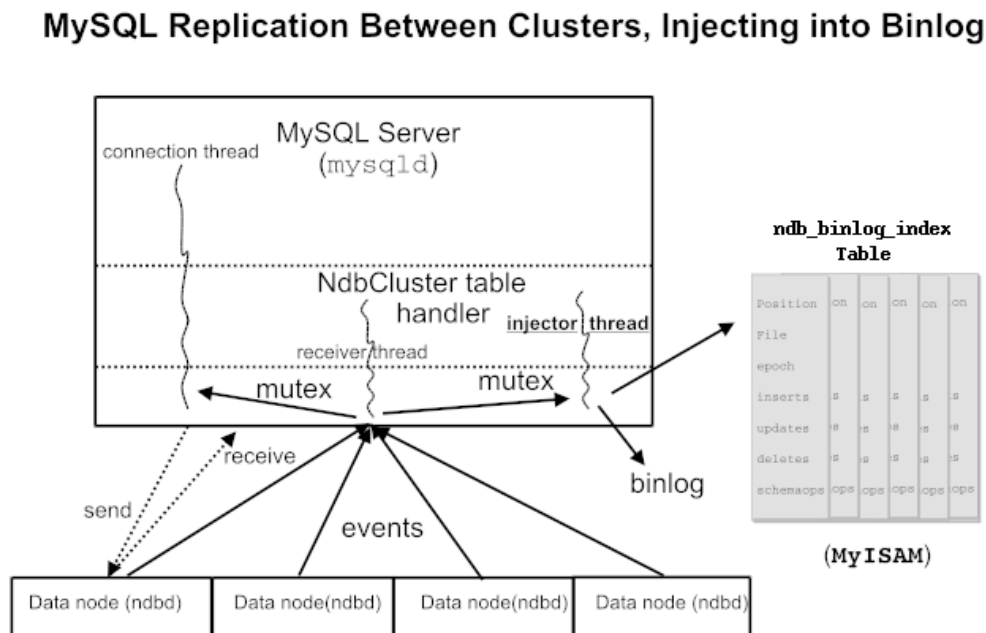
Beginning with MySQL Cluster NDB 6.3.2, this table has been changed to facilitate 3-way replication recovery. Two columns `orig_server_id` and `orig_epoch` have been added to this table; when `mysqld` is started with the `--ndb-log-orig` option, these columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server. In addition, the table's primary key now includes these two columns. The modified table definition is shown here:

```
CREATE TABLE `ndb_binlog_index` (
    `Position` BIGINT(20) UNSIGNED NOT NULL,
    `File` VARCHAR(255) NOT NULL,
    `epoch` BIGINT(20) UNSIGNED NOT NULL,
    `inserts` INT(10) UNSIGNED NOT NULL,
    `updates` INT(10) UNSIGNED NOT NULL,
    `deletes` INT(10) UNSIGNED NOT NULL,
    `schemaops` INT(10) UNSIGNED NOT NULL,
    `orig_server_id` INT(10) UNSIGNED NOT NULL,
    `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
    `gci` INT(10) UNSIGNED NOT NULL,
    `next_position` bigint(20) unsigned NOT NULL,
    `next_file` varchar(255) NOT NULL,
    PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

The `gci` column was added in MySQL Cluster NDB 6.2.6 and MySQL Cluster NDB 6.3.2.

The `next_position` and `next_file` columns were added in MySQL Cluster NDB 7.0.33 and MySQL Cluster NDB 7.1.22; see Section 17.6.8, "Implementing Failover with MySQL Cluster Replication", for more information about using these columns.

The following figure shows the relationship of the MySQL Cluster replication master server, its binlog injector thread, and the `mysql.ndb_binlog_index` table.

Figure 17.17 The Replication Master Cluster


An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
    `server_id`    INT(10) UNSIGNED NOT NULL,
    `epoch`        BIGINT(20) UNSIGNED NOT NULL,
    `log_name`     VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
    `start_pos`    BIGINT(20) UNSIGNED NOT NULL,
    `end_pos`      BIGINT(20) UNSIGNED NOT NULL,
    PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER   DEFAULT CHARSET=latin1;
```

The `ndb_apply_status` table is populated only on slaves, which means that, on the master, this table never contains any rows; thus, there is no need to allow for `DataMemory` or `IndexMemory` to be allotted to `ndb_apply_status` there.

Because this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating `ndb_apply_status` or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see Replication and binary log filtering rules with replication between MySQL Clusters.

The `log_name`, `start_pos`, and `end_pos` columns were added in MySQL 5.1.18.

> **Important**
>
> If you are using MySQL Cluster replication, see Section 17.2.7.3, "Upgrade and downgrade compatibility: MySQL 5.1" before upgrading to MySQL 5.1.18 or later from an earlier version.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both `ndb_binlog_index` and the `ndb_apply_status` are maintained by the `NDB` binary log (binlog) injector thread. This keeps the master `mysqld` process updated to changes performed by the `NDB` storage engine. The `NDB` *binlog injector thread* receives events directly from the `NDB` storage engine. The `NDB` injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing a MySQL Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See Section 13.7.5.3, "SHOW BINLOG EVENTS Syntax".)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

The `ndb_schema` table is used to track schema changes made to `NDB` tables. It is defined as shown here:

```
CREATE TABLE ndb_schema (
    `db` VARBINARY(63) NOT NULL,
```

```
    `name` VARBINARY(63) NOT NULL,
    `slock` BINARY(32) NOT NULL,
    `query` BLOB NOT NULL,
    `node_id` INT UNSIGNED NOT NULL,
    `epoch` BIGINT UNSIGNED NOT NULL,
    `id` INT UNSIGNED NOT NULL,
    `version` INT UNSIGNED NOT NULL,
    `type` INT UNSIGNED NOT NULL,
    PRIMARY KEY USING HASH (db,name)
) ENGINE=NDB   DEFAULT CHARSET=latin1;
```

Unlike the two tables previously mentioned in this section, the `ndb_schema` table is not visible either to MySQL `SHOW` statements, or in any `INFORMATION_SCHEMA` tables; however, it can be seen in the output of `ndb_show_tables`, as shown here:

```
shell> ndb_show_tables -t 2
id    type                state    logging database    schema    name
4     UserTable           Online   Yes     mysql        def       ndb_apply_status
5     UserTable           Online   Yes     ndbworld     def       city
6     UserTable           Online   Yes     ndbworld     def       country
3     UserTable           Online   Yes     mysql        def       NDB$BLOB_2_3
7     UserTable           Online   Yes     ndbworld     def       countrylanguage
2     UserTable           Online   Yes     mysql        def       ndb_schema

NDBT_ProgramExit: 0 - OK
```

It is also possible to `SELECT` from this table in `mysql` and other MySQL client applications, as shown here:

```
mysql> SELECT * FROM mysql.ndb_schema WHERE name='city' \G
*************************** 1. row ***************************
     db: ndbworld
   name: city
  slock:
  query: alter table city engine=ndb
node_id: 4
  epoch: 0
     id: 0
version: 0
   type: 7
1 row in set (0.00 sec)
```

This can sometimes be useful when debugging applications.

> **Note**
>
> When performing schema changes on `NDB` tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

The `ndb_schema` table was added in MySQL 5.1.8.

Beginning with MySQL 5.1.14, if the `ndb_apply_status` table or the `ndb_schema` table does not exist on the slave, `ndb_restore` re-creates the missing table or tables (Bug #14612).

Conflict resolution for MySQL Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see Section 17.6.11, "MySQL Cluster Replication Conflict Resolution".

17.6.5 Preparing the MySQL Cluster for Replication

Preparing the MySQL Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see Section 17.6.2, "General Requirements for MySQL Cluster Replication").

2. Create a slave account on the master Cluster with the appropriate privileges:

```
mysqlM> GRANT REPLICATION SLAVE
    -> ON *.* TO 'slave_user'@'slave_host'
    -> IDENTIFIED BY 'slave_password';
```

In the previous statement, `slave_user` is the slave account user name, `slave_host` is the host name or IP address of the replication slave, and `slave_password` is the password to assign to this account.

For example, to create a slave user account with the name "`myslave`," logging in from the host named "`rep-slave`," and using the password "`53cr37`," use the following `GRANT` statement:

```
mysqlM> GRANT REPLICATION SLAVE
    -> ON *.* TO 'myslave'@'rep-slave'
    -> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
    -> MASTER_HOST='master_host',
    -> MASTER_PORT=master_port,
    -> MASTER_USER='slave_user',
    -> MASTER_PASSWORD='slave_password';
```

In the previous statement, `master_host` is the host name or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the user name set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is "`rep-master`," using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
    -> MASTER_HOST='rep-master',
    -> MASTER_PORT=3306,
    -> MASTER_USER='myslave',
    -> MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see Section 13.4.2.1, "CHANGE MASTER TO Syntax".

To provide replication backup capability, you also need to add an `--ndb-connectstring` option to the slave's `my.cnf` file prior to starting the replication process. See Section 17.6.9, "MySQL Cluster Backups With MySQL Cluster Replication", for details.

For additional options that can be set in `my.cnf` for replication slaves, see Section 16.1.3, "Replication and Binary Logging Options and Variables".

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running MySQL Cluster, this can be accomplished using the backup and restore procedure described in Section 17.6.9, "MySQL Cluster Backups With MySQL Cluster Replication".

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using MySQL Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shellM> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where *dump_file* is the name of the file that was generated using `mysqldump` on the master, and *db_name* is the name of the database to be replicated:

```
shellS> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see Section 4.5.4, "`mysqldump` — A Database Backup Program".

> **Note**
>
> If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See Section 16.1.2, "Replication Formats".) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See Section 17.6.6, "Starting MySQL Cluster Replication (Single Replication Channel)", for information regarding the latter option.

17.6.6 Starting MySQL Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting MySQL Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --ndbcluster --server-id=id \
        --log-bin --binlog-format=ROW &
```

In the previous statement, *id* is this server's unique ID (see Section 17.6.2, "General Requirements for MySQL Cluster Replication"). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

> **Note**
>
> You can also start the master with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. `STATEMENT` based binary logging is not supported for MySQL Cluster Replication (see Section 17.6.2, "General Requirements for MySQL Cluster Replication").

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

In the command just shown, `id` is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

> **Note**
>
> You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server's replication binary log. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysqlS> CHANGE MASTER TO
     -> MASTER_LOG_FILE='',
     -> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise—that is, if you are loading data from the master using a backup—see Section 17.6.8, "Implementing Failover with MySQL Cluster Replication", for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysqlS> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Section 17.6.7, "Using Two Replication Channels for MySQL Cluster Replication".

Beginning with MySQL Cluster NDB 6.2.3, it is possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` system variable on the slave `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

> **Note**
>
> Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.
>
> All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate SHOW VARIABLES statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| slave_allow_batching     | ON    |
| slave_compressed_protocol | OFF  |
| slave_load_tmpdir        | /tmp  |
| slave_net_timeout        | 3600  |
| slave_skip_errors        | OFF   |
| slave_transaction_retries | 10   |
+--------------------------+-------+
6 rows in set (0.00 sec)
```

17.6.7 Using Two Replication Channels for MySQL Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

Server ID	Description
1	Master - primary replication channel (*M*)
2	Master - secondary replication channel (*M'*)
3	Slave - primary replication channel (*S*)
4	Slave - secondary replication channel (*S'*)

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the mysqld processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the START SLAVE statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```
shellM> mysqld --ndbcluster --server-id=1 \
               --log-bin --binlog-format=ROW &
```

2. Start the secondary replication master:

```
shellM'> mysqld --ndbcluster --server-id=2 \
                --log-bin --binlog-format=ROW &
```

3. Start the primary replication slave server:

```
shellS> mysqld --ndbcluster --server-id=3 \
               --skip-slave-start &
```

4. Start the secondary replication slave:

```
shellS'> mysqld --ndbcluster --server-id=4 \
                --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the START SLAVE statement on the primary slave as shown here:

```
mysqlS> START SLAVE;
```

> **Warning**
>
> Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in Section 17.6.8, "Implementing Failover with MySQL Cluster Replication". Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

17.6.8 Implementing Failover with MySQL Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the ndb_apply_status table on the slave cluster, which can be found using the following query:

```
mysqlS'> SELECT @latest:=MAX(epoch)
      ->        FROM mysql.ndb_apply_status;
```

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the ndb_binlog_index table on the master cluster.

Prior to MySQL Cluster NDB 7.0.33 and MySQL Cluster 7.1.22, you should use the following query to accomplish this task:

```
mysqlM'> SELECT
```

```
        ->      @file:=SUBSTRING_INDEX(File, '/', -1),
        ->      @pos:=Position
        -> FROM mysql.ndb_binlog_index
        -> WHERE epoch > @latest
        -> ORDER BY epoch ASC LIMIT 1;
```

Beginning with MySQL Cluster NDB 7.0.33 and MySQL Cluster NDB 7.1.22, you can take advantage of the improved binary logging of DDL statements implemented in those and later versions by using the following query to obtain the needed records from the master's `ndb_binlog_index` table:

```
mysqlM'> SELECT
        ->      @file:=SUBSTRING_INDEX(next_file, '/', -1),
        ->      @pos:=next_position
        -> FROM mysql.ndb_binlog_index
        -> WHERE epoch = @latest
        -> ORDER BY epoch ASC LIMIT 1;
```

In either case, these are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be "plugged in" to the second query manually or in application code.

> ⚠️ **Important**
>
> If (and only if) you use the second of the two queries just shown against `ndb_binlog_index` (that is, the query that employs the `next_position` and `next_file` columns), you must ensure that the slave `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS'> CHANGE MASTER TO
        ->      MASTER_LOG_FILE='@file',
        ->      MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

> 📝 **Note**
>
> `@file` is a string value such as `'/var/log/mysql/replication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqld`:

```
mysqlS'> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from M to S', or from M' to S; however, this has not yet been tested.

17.6.9 MySQL Cluster Backups With MySQL Cluster Replication

This section discusses making backups and restoring from them using MySQL Cluster replication. We assume that the replication servers have already been configured as covered previously (see Section 17.6.5, "Preparing the MySQL Cluster for Replication", and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

   - **Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf file`, where *management_host* is the IP address or host name of the `NDB` management server for the master cluster, and *port* is the management server's port number:

   ```
   ndb-connectstring=management_host[:port]
   ```

   Note

   The port number needs to be specified only if the default port (1186) is not being used. See Section 17.2.3, "Initial Configuration of MySQL Cluster", for more information about ports and port allocation in MySQL Cluster.

   In this case, the backup can be started by executing this statement on the replication master:

   ```
   shellM> ndb_mgm -e "START BACKUP"
   ```

   - **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the `NDB` management client as part of the `START BACKUP` command. This can be done as shown here, where *management_host* and *port* are the host name and port number of the management server:

   ```
   shellM> ndb_mgm management_host:port -e "START BACKUP"
   ```

   In our scenario as outlined earlier (see Section 17.6.5, "Preparing the MySQL Cluster for Replication"), this would be executed as follows:

   ```
   shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
   ```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It *is* necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

   > **Important**
   >
   > A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

   ```
   mysqlS> RESET SLAVE;
   ```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

   ```
   shellS> ndb_restore -c slave_host:port -n node-id \
           -b backup-id -m -r dir
   ```

   `dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

   For restoring from a master cluster with four data nodes (as shown in the figure in Section 17.6, "MySQL Cluster Replication") where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

   ```
   shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
           -r ./var/BACKUPS/BACKUP-1
   shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
           -r ./var/BACKUPS/BACKUP-1
   shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
           -r ./var/BACKUPS/BACKUP-1
   shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
           -r ./var/BACKUPS/BACKUP-1
   ```

   > **Important**
   >
   > The `-e` (or `--restore_epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup".)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in Section 17.6.8, "Implementing Failover with MySQL Cluster Replication"):

   ```
   mysqlS> SELECT @latest:=MAX(epoch)
           FROM mysql.ndb_apply_status;
   ```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysqlM> SELECT
    ->     @file:=SUBSTRING_INDEX(File, '/', -1),
    ->     @pos:=Position
    -> FROM mysql.ndb_binlog_index
    -> WHERE epoch > @latest
    -> ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysqlS> CHANGE MASTER TO
    ->     MASTER_LOG_FILE='@file',
    ->     MASTER_LOG_POS=@pos;
```

9. Now that the slave "knows" from what point in which `binlog` file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysqlS> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Section 17.5.3, "Online Backup of MySQL Cluster".

17.6.9.1 MySQL Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see Section 17.6.9, "MySQL Cluster Backups With MySQL Cluster Replication"). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

17.6.9.2 Point-In-Time Recovery Using MySQL Cluster Replication

Point-in-time recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of MySQL Cluster tables with MySQL Cluster and MySQL Cluster Replication can be accomplished using a native `NDB` data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of MySQL Cluster, it is necessary to follow the steps shown here:

1. Back up all `NDB` databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see Section 17.5.3, "Online Backup of MySQL Cluster").

2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.

   This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (*Catastrophic failure or error occurs.*)

4. Locate the last known good backup.

5. Clear the data node file systems (using `ndbd --initial` or, in MySQL Cluster NDB 7.0 and later, `ndbmtd --initial`).

   > **Note**
   >
   > MySQL Cluster Disk Data tablespace and log files are not removed by `--initial`. You must delete these manually.

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.

7. Execute `ndb_restore`, restoring all data. You must include the `--restore_epoch` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See Section 17.4.20, "`ndb_restore` — Restore a MySQL Cluster Backup", for more information.)

8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.

9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

```
SELECT @LATEST_EPOCH:=MAX(epoch)
    FROM mysql.ndb_apply_status;
```

10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

```
SELECT Position, @FIRST_FILE:=File
    FROM mysql.ndb_binlog_index
    WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See Section 4.6.7, "`mysqlbinlog` — Utility for Processing Binary Log Files".)

See also Section 7.5, "Point-in-Time (Incremental) Recovery Using the Binary Log", for more information about the binary log, replication, and incremental recovery.

17.6.10 MySQL Cluster Replication: Multi-Master and Circular Replication

Beginning with MySQL 5.1.18, it is possible to use MySQL Cluster in multi-master replication, including circular replication between a number of MySQL Clusters.

> **Note**
>
> Prior to MySQL 5.1.18, multi-master replication including circular replication was not supported with MySQL Cluster replication. This was because log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the master rather than the server ID of the originating server.

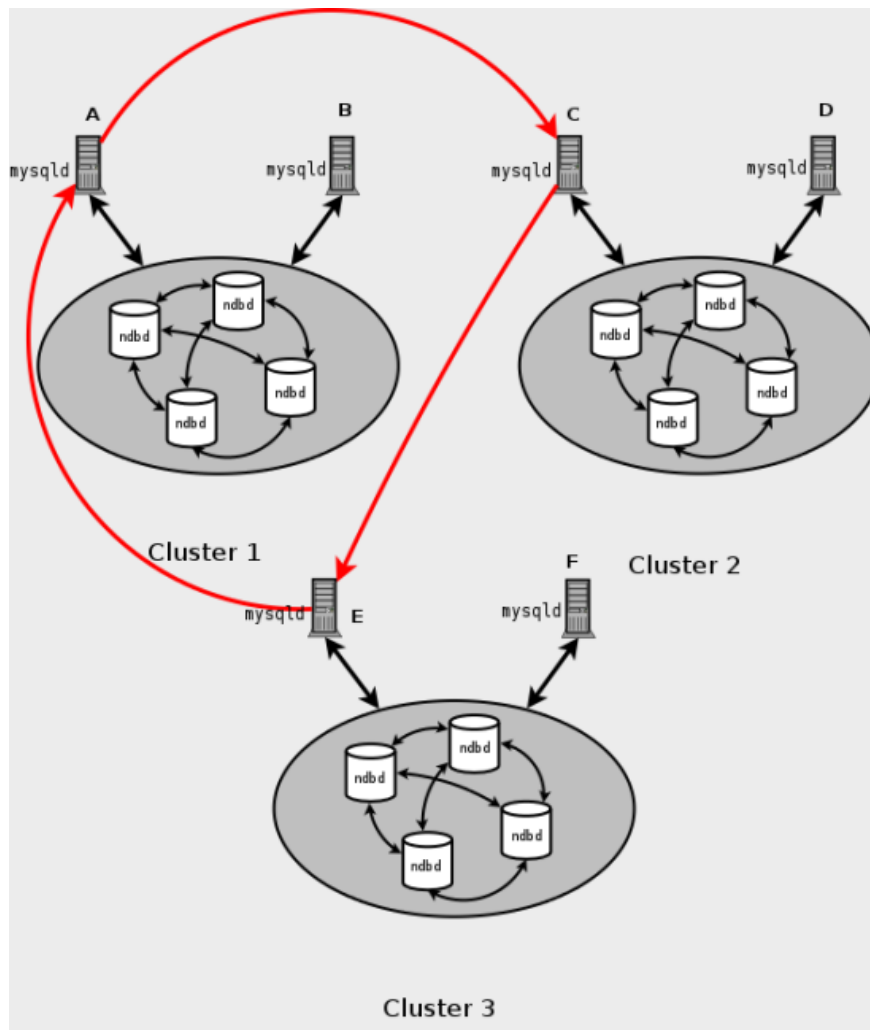
Circular replication example.   In the next few paragraphs we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same

- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

Figure 17.18 MySQL Cluster Circular Replication with All Masters As Slaves


In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:

Figure 17.19 MySQL Cluster Circular Replication Where Not All Masters Are Slaves
In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates`. This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

Using NDB-native backup and restore to initialize a slave MySQL Cluster.   When setting up circular replication, it is possible to initialize the slave cluster by using the management client `BACKUP` command on one MySQL Cluster to create a backup and then applying this backup on another MySQL Cluster using `ndb_restore`. However, this does not automatically create binary logs on the second MySQL Cluster's SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`.

This is a known issue which we intend to address in a future release.

Multi-master failover example.   In this section, we discuss failover in a multi-master MySQL Cluster replication setup with three MySQL Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

Figure 17.20 MySQL Cluster Multi-Master Replication With 3 Masters
In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given MySQL Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

Figure 17.21 MySQL Cluster Multi-Master Replication, With MySQL Servers
MySQL servers acting as replication slaves must be run with the `--log-slave-updates` option. Which `mysqld` processes require this option is also shown in the preceding diagram.

> **Note**
>
> Using the `--log-slave-updates` option has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1.

Because replication between MySQL Clusters is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
     ->      FROM mysql.ndb_apply_status
     ->      WHERE server_id=1;

mysqlC> SELECT
     ->      @file:=SUBSTRING_INDEX(File, '/', -1),
     ->      @pos:=Position
     ->      FROM mysql.ndb_binlog_index
     ->      WHERE orig_epoch >= @latest
     ->      AND orig_server_id = 1
     ->      ORDER BY epoch ASC LIMIT 1;
```

> **Note**
>
> You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See Section 17.6.4, "MySQL Cluster Replication Schema and Tables", for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
     ->      MASTER_HOST = 'serverC'
     ->      MASTER_LOG_FILE='@file',
     ->      MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

Beginning with MySQL Cluster MySQL Cluster NDB 6.1.29, MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.0, the `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see Section 13.4.2.1, "CHANGE MASTER TO Syntax", and Section 13.7.5.36, "SHOW SLAVE STATUS Syntax".

17.6.11 MySQL Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in MySQL Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given master should be applied on the slave.

Some types of conflict resolution supported by MySQL Cluster (`NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`) implement this user-defined column as a "timestamp" column (although its type cannot be `TIMESTAMP`, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions introduced in MySQL Cluster NDB 7.1.16 (`NDB$EPOCH()` and `NDB$EPOCH_TRANS()`) compare the order

in which epochs are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

You should also keep in mind that it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

Requirements. Preparations for conflict resolution must be made on both the master and the slave. These tasks are described in the following list:

- On the master writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table (see The ndb_replication system table).

  > **Note**
  >
  > If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the master and slave binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.
  >
  > See Section 16.4.1.21, "Replication and max_allowed_packet", for more information about this issue.

- On the slave, you must determine which type of conflict resolution to apply ("latest timestamp wins", "same timestamp wins", or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis (see The ndb_replication system table).

- Prior to MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, conflict detection and resolution did not always work properly unless set up for `NDB` tables created on the same server only (Bug #13578660).

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a "timestamp" column, but the data type of this column is never `TIMESTAMP`; rather, its data type should be `INT` (`INTEGER`) or `BIGINT`. The "timestamp" column should also be `UNSIGNED` and `NOT NULL`.

Master column control. We can see update operations in terms of "before" and "after" images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the "before" image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master's binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

> **Important**
>
> Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

Logging Full or Partial Rows (--ndb-log-updated-only Option)

Introduced	5.1.19-ndb-6.3.0

Command-Line Format	--ndb-log-updated-only	
System Variable	**Name**	`ndb_log_updated_only`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`boolean`
	Default	`ON`

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows

- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to `0` or `OFF`.

--ndb-log-update-as-write Option: Logging Changed Data as Updates

Introduced	5.1.22-ndb-6.2.5	
Command-Line Format	--ndb-log-update-as-write	
System Variable	**Name**	`ndb_log_update_as_write`
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	**Type**	`boolean`
	Default	`ON`

The setting of the MySQL Server's `--ndb-log-update-as-write` option determines whether logging is performed with or without the "before" image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; in other words, updates are treated as writes. (That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.)

To turn off the option, start the master `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`. You must do this when replicating from NDB tables to tables using a different storage engine; see Replication from NDB to other storage engines.

Conflict resolution control.   Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

The ndb_replication system table.   To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication.

`ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple master-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```
CREATE TABLE mysql.ndb_replication  (
    db VARBINARY(63),
    table_name VARBINARY(63),
    server_id INT UNSIGNED,
    binlog_type INT UNSIGNED,
    conflict_fn VARBINARY(128),
    PRIMARY KEY USING HASH (db, table_name, server_id)
)   ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns in this table are described in the next few paragraphs.

db.   The name of the database containing the table to be replicated.

Beginning with MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, you may employ either or both of the wildcards _ and % as part of the database name. Matching is similar to what is implemented for the `LIKE` operator.

table_name.   The name of the table to be replicated.

Beginning with MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, the table name may include either or both of the wildcards _ and %. Matching is similar to what is implemented for the `LIKE` operator.

server_id.   The unique server ID of the MySQL instance (SQL node) where the table resides.

binlog_type.   The type of binary logging to be employed. This is determined as shown in the following table:

Value	Internal Value	Description
0	`NBT_DEFAULT`	Use server default
1	`NBT_NO_LOGGING`	Do not log this table in the binary log
2	`NBT_UPDATED_ONLY`	Only updated attributes are logged
3	`NBT_FULL`	Log full row, even if not updated (MySQL server default behavior)
4	`NBT_USE_UPDATE`	(For generating `NBT_UPDATED_ONLY_USE_UPDATE` and `NBT_FULL_USE_UPDATE` values only—not intended for separate use)
5	[*Not used*]	---
6	`NBT_UPDATED_ONLY_USE_UPDATE` (equal to `NBT_UPDATED_ONLY` | `NBT_USE_UPDATE`)	Use updated attributes, even if values are unchanged
7	`NBT_FULL_USE_UPDATE` (equal to `NBT_FULL` | `NBT_USE_UPDATE`)	Use full row, even if values are unchanged

conflict_fn.   The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:

- NDB$OLD(column_name)

- NDB$MAX(column_name)

- NDB$MAX_DELETE_WIN(column_name)

- NDB$EPOCH() and NDB$EPOCH_TRANS() (MySQL Cluster NDB 7.1.16 and later)

- NDB$EPOCH_TRANS() (MySQL Cluster NDB 7.1.16 and later)

- `NULL`: Indicates that conflict resolution is not to be used for the corresponding table.

These functions are described in the next few paragraphs.

NDB$OLD(column_name). If the value of `column_name` is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (master_old_column_value == slave_current_column_value)
  apply_update();
else
  log_exception();
```

 This function can be used for "same value wins" conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

> **Important**
>
> The column value from the master's "before" image is used by this function.

NDB$MAX(column_name). If the "timestamp" column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```
if (master_new_column_value > slave_current_column_value)
  apply_update();
```

 This function can be used for "greatest timestamp wins" conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

> **Important**
>
> The column value from the master's "after" image is used by this function.

NDB$MAX_DELETE_WIN(column_name). This is a variation on `NDB$MAX()`. Due to the fact that no timestamp is available for a delete operation, a delete using `NDB$MAX()` is in fact processed as `NDB$OLD`. However, for some use cases, this is not optimal. For `NDB$MAX_DELETE_WIN()`, if the "timestamp" column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied. However, delete operations are treated as always having the higher value. This is illustrated in the following pseudocode:

```
if ( (master_new_column_value > slave_current_column_value)
        ||
      operation.type == "delete")
  apply_update();
```

This function can be used for "greatest timestamp, delete wins" conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

Note

As with `NDB$MAX()`, the column value from the master's "after" image is the value used by this function.

NDB$EPOCH() and NDB$EPOCH_TRANS().   The `NDB$EPOCH()` function, available beginning with MySQL Cluster NDB 7.1.16, tracks the order in which replicated epochs are applied on a slave MySQL Cluster relative to changes originating on the slave. This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of `NDB$EPOCH()` also applies to `NDB$EPOCH_TRANS()`. Any exceptions are noted in the text.

`NDB$EPOCH()` is asymmetric, operating on one MySQL Cluster in a two-cluster circular replication configuration (sometimes referred to as "active-active" replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The slave on the primary is responsible for detecting and handling conflicts, while the slave on the secondary is not involved in any conflict detection or handling.

When the slave on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary MySQL Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary MySQL Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This "primary always wins" rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and will not be undone or rolled back by conflict detection and resolution.

- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the slave) will not be reverted later.

- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.

- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.

- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For `NDB$EPOCH_TRANS()`, this is a transient state; for `NDB$EPOCH()`, it can be a persistent state.

- Assuming a period of sufficient length without any conflicts, all data on the secondary MySQL Cluster (eventually) becomes consistent with the primary's data.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than

```
CEIL( LOG2( TimeBetweenGlobalCheckpoints / TimeBetweenEpochs ), 1)
```

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for `TimeBetweenGlobalCheckpoints`, `TimeBetweenEpochs`, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exception table schema rules as described elsewhere in this section (see NDB$OLD(column_name)). Note that you need to create any exception table before creating the table with which it is to be used.

As with the other conflict detection functions discussed in this section, `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are activated by including relevant entries in the `mysql.ndb_replication` table (see The ndb_replication system table). The roles of the primary and secondary MySQL Clusters in this scenario are fully determined by `mysql.ndb_replication` table entries.

Because the conflict detection algorithms employed by `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are asymmetric, you must use different values for the primary slave's and secondary slave's `server_id` entries.

Prior to MySQL Cluster NDB 7.1.32, conflict between `DELETE` operations were handled like those for `UPDATE` operations, and within the same epoch were considered in conflict. In MySQL Cluster NDB 7.1.32 and later, a conflict between `DELETE` operations alone is not sufficient to trigger a conflict using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`, and the relative placement within epochs does not matter. (Bug "18454499)

NDB$EPOCH() and NDB$EPOCH_TRANS() status variables.   MySQL Cluster NDB 7.1.16 introduces several status variables that can be used to monitor `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` conflict detection. You can see how many rows have been found in conflict by `NDB$EPOCH()` since this slave was last restarted from the current value of the `Ndb_conflict_fn_epoch` system status variable.

`Ndb_conflict_fn_epoch_trans` provides the number of rows that have been found directly in conflict by `NDB$EPOCH_TRANS()`; the number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by `Ndb_conflict_trans_row_reject_count`.

For more information, see MySQL Cluster Status Variables.

Limitations on NDB$EPOCH().   The following limitations currently apply when using `NDB$EPOCH()` to perform conflict detection:

- Conflicts are detected using MySQL Cluster epoch boundaries, with granularity proportional to `TimeBetweenEpochs` (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to `2 * (latency + queueing + TimeBetweenEpochs)`. This implies that—assuming the default for `TimeBetweenEpochs` and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application "race" patterns.

- Additional storage is required for tables using the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.

- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations will not be detected, which can lead to divergence.

Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two MySQL Clusters in a circular "active-active" configuration are currently supported when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` for conflict detection.

- Tables having `BLOB` or `TEXT` columns are not currently supported with `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`.

NDB$EPOCH_TRANS().   `NDB$EPOCH_TRANS()` extends the `NDB$EPOCH()` function, and, like `NDB$EPOCH()`, is available beginning with MySQL Cluster NDB 7.1.16. Conflicts are detected and handled in the same way using the "primary wins all" rule (see NDB$EPOCH() and NDB$EPOCH_TRANS()) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where `NDB$EPOCH()` realigns individual conflicting rows on the secondary, `NDB$EPOCH_TRANS()` realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster's binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

`NDB$EPOCH_TRANS()` is subject to the same conditions and limitations as `NDB$EPOCH()`, and in addition requires that Version 2 binary log row events are used (`--log-bin-use-v1-row-events` equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all transaction IDs must be recorded in the secondary's binary log (`--ndb-log-transaction-id` option), which adds a further variable overhead (up to 13 bytes per row).

See NDB$EPOCH() and NDB$EPOCH_TRANS().

Status information.   Beginning with MySQL Cluster NDB 6.3.3, a server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to "greatest timestamp wins" conflict resolution since the last time that `mysqld` was started.

Beginning with MySQL Cluster NDB 6.3.4, the number of times that a row was not applied as the result of "same timestamp wins" conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an *exceptions table*, as explained later in this section.

Exceptions table.   To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` in MySQL Cluster NDB 7.1.16 and later. The name of this table is that of the table for which conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exception table name should be `mytable$EX`.) This table is created as follows:

```
CREATE TABLE original_table$EX  (
    server_id INT UNSIGNED,
    master_server_id INT UNSIGNED,
    master_epoch BIGINT UNSIGNED,
    count INT UNSIGNED,
    original_table_pk_columns,
    [additional_columns,]
    PRIMARY KEY(server_id, master_server_id, master_epoch, count)
```

```
) ENGINE=NDB;
```

The first four columns are required. Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table.

Note

The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `master_server_id`, `master_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

The data types for the columns duplicating the primary key columns of the original table should be the same as for (or larger than) the original columns.

Additional columns may optionally be defined following these columns, but not before any of them; any such extra columns cannot be `NOT NULL`. The exception table's primary key must be defined as shown. The exception table must use the `NDB` storage engine. An example that uses `NDB$OLD()` with an exceptions table is shown later in this section.

Important

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* the table to be replicated is created.

Examples

The following examples assume that you have already a working MySQL Cluster replication setup, as described in Section 17.6.5, "Preparing the MySQL Cluster for Replication", and Section 17.6.6, "Starting MySQL Cluster Replication (Single Replication Channel)".

NDB$MAX() example.   Suppose you wish to enable "greatest timestamp wins" conflict resolution on table `test.t1`, using column `mycol` as the "timestamp". This can be done using the following steps:

1. Make sure that you have started the master `mysqld` with `--ndb-log-update-as-write=OFF`.

2. On the master, perform this `INSERT` statement:

   ```
   INSERT INTO mysql.ndb_replication
       VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
   ```

   Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

   Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

   ```
   CREATE TABLE test.t1 (
       columns
       mycol INT UNSIGNED,
       columns
   ```

```
)    ENGINE=NDB;
```

Now, when updates are done on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the slave.

> **Note**
>
> Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE` should be used to control logging on the master using the `ndb_replication` table rather than by using command-line options.

NDB$OLD() example.   Suppose an `NDB` table such as the one defined here is being replicated, and you wish to enable "same timestamp wins" conflict resolution for updates to this table:

```
CREATE TABLE test.t2  (
    a INT UNSIGNED NOT NULL,
    b CHAR(25) NOT NULL,
    columns,
    mycol INT UNSIGNED NOT NULL,
    columns,
    PRIMARY KEY pk (a, b)
)    ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

   ```
   INSERT INTO mysql.ndb_replication
       VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
   ```

   Possible values for the `binlog_type` column are shown earlier in this section. The value `'NDB$OLD(mycol)'` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

   ```
   CREATE TABLE test.t2$EX  (
       server_id SMALLINT UNSIGNED,
       master_server_id INT UNSIGNED,
       master_epoch BIGINT UNSIGNED,
       count BIGINT UNSIGNED,
       a INT UNSIGNED NOT NULL,
       b CHAR(25) NOT NULL,
       [additional_columns,]
       PRIMARY KEY(server_id, master_server_id, master_epoch, count)
   )    ENGINE=NDB;
   ```

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

17.7 MySQL Cluster NDB 6.1 - 7.1 Release Notes

MySQL Cluster release notes are no longer published in the MySQL Reference Manual.

Release notes for the changes in each release of MySQL Cluster are located at MySQL Cluster 7.1 Release Notes.

Table of Contents

This chapter discusses MySQL's implementation of *user-defined partitioning*. You can determine whether your MySQL Server supports partitioning by means of a SHOW VARIABLES statement such as this one:

> **Note**
>
> The have_partitioning variable is deprecated, and removed in MySQL 5.6.1.

```
mysql> SHOW VARIABLES LIKE '%partition%';

+-------------------+-------+
| Variable_name     | Value |
+-------------------+-------+
| have_partitioning | YES   |
+-------------------+-------+
1 row in set (0.00 sec)
```

> **Note**
>
> Prior to MySQL 5.1.6, this variable was named have_partition_engine. (Bug #16718)

You can also check the output of the SHOW PLUGINS statement, like this:

```
mysql> SHOW PLUGINS;
+------------+----------+----------------+---------+---------+
| Name       | Status   | Type           | Library | License |
+------------+----------+----------------+---------+---------+
```

```
| binlog      | ACTIVE   | STORAGE ENGINE | NULL     | GPL     |
| partition   | ACTIVE   | STORAGE ENGINE | NULL     | GPL     |
| ARCHIVE     | ACTIVE   | STORAGE ENGINE | NULL     | GPL     |
| BLACKHOLE   | ACTIVE   | STORAGE ENGINE | NULL     | GPL     |
| CSV         | ACTIVE   | STORAGE ENGINE | NULL     | GPL     |
| FEDERATED   | DISABLED | STORAGE ENGINE | NULL     | GPL     |
| MEMORY      | ACTIVE   | STORAGE ENGINE | NULL     | GPL     |
| InnoDB      | ACTIVE   | STORAGE ENGINE | NULL     | GPL     |
| MRG_MYISAM  | ACTIVE   | STORAGE ENGINE | NULL     | GPL     |
| MyISAM      | ACTIVE   | STORAGE ENGINE | NULL     | GPL     |
| ndbcluster  | DISABLED | STORAGE ENGINE | NULL     | GPL     |
+-----------+---------+----------------+---------+---------+
11 rows in set (0.00 sec)
```

In MySQL 5.1.5 and later, you can also check the `INFORMATION_SCHEMA.PLUGINS` table with a query similar to this one:

```
mysql> SELECT
    ->      PLUGIN_NAME as Name,
    ->      PLUGIN_VERSION as Version,
    ->      PLUGIN_STATUS as Status
    -> FROM INFORMATION_SCHEMA.PLUGINS
    -> WHERE PLUGIN_TYPE='STORAGE ENGINE';
+--------------------+---------+--------+
| Name               | Version | Status |
+--------------------+---------+--------+
| binlog             | 1.0     | ACTIVE |
| CSV                | 1.0     | ACTIVE |

```

Whichever of the preceding statements you employ, if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output (shown in bold text in each of the examples just given), then your version of MySQL was not built with partitioning support.

MySQL 5.1 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in MySQL Enterprise Edition binaries, see Chapter 23, *MySQL Enterprise Edition*.

If you are compiling MySQL 5.1 from source, the build must be configured using `--with-partition` to enable partitioning. Using `--with-plugins=max` to configure the build includes this option automatically. For more information, see Section 2.11, "Installing MySQL from Source".

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option, in which case the value of `have_partitioning` is `DISABLED`. When partitioning support is disabled, you can see any existing partitioned tables and drop them (although doing this is not advised), but you cannot otherwise manipulate them or access their data.

See Section 18.1, "Overview of Partitioning in MySQL", for an introduction to partitioning and partitioning concepts.

MySQL supports several types of partitioning as well as subpartitioning; see Section 18.2, "Partitioning Types", and Section 18.2.5, "Subpartitioning".

Section 18.3, "Partition Management", covers methods of adding, removing, and altering partitions in existing partitioned tables.

Section 18.3.3, "Maintenance of Partitions", discusses table maintenance commands for use with partitioned tables.

Beginning with MySQL 5.1.6, the `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See Section 20.11, "The INFORMATION_SCHEMA PARTITIONS Table", for more information; for some examples of queries against this table, see Section 18.2.6, "How MySQL Partitioning Handles NULL".

> **Important**
>
> Partitioned tables created with MySQL versions prior to 5.1.6 cannot be read by a 5.1.6 or later MySQL Server. In addition, the `INFORMATION_SCHEMA.TABLES` table cannot be used if such tables are present on a 5.1.6 server. Beginning with MySQL 5.1.7, a suitable warning message is generated instead, to alert the user that incompatible partitioned tables have been found by the server.
>
> If you are using partitioned tables which were created in MySQL 5.1.5 or earlier, be sure to see the Release Notes for MySQL 5.1.6 for more information and suggested workarounds *before* upgrading to MySQL 5.1.6 or later.

For known issues with partitioning in MySQL 5.1, see Section 18.5, "Restrictions and Limitations on Partitioning".

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources.   Other sources of information about user-defined partitioning in MySQL include the following:

- MySQL Partitioning Forum

  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- Mikael Ronström's Blog

  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- PlanetMySQL

  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.1 binaries are available from http://dev.mysql.com/downloads/mysql/5.1.html. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our Bazaar repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see Section 2.11, "Installing MySQL from Source". If you have problems compiling a partitioning-enabled MySQL 5.1 build, check the MySQL Partitioning Forum and ask for assistance there if you do not find a solution to your problem already posted.

18.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.1.

For information on partitioning restrictions and feature limitations, see Section 18.5, "Restrictions and Limitations on Partitioning".

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 8.12.4, "Using Symbolic Links", for an explanation of how this is done).

Partitioning takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of `RANGE`, `LIST`, and [`LINEAR`] `HASH` partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer *intval* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.)

For [`LINEAR`] `KEY`, the partitioning expression consists of a list of one or more columns, and the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see Section 18.2, "Partitioning Types", as well as Section 13.1.17, "CREATE TABLE Syntax", which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see Section 18.5.3, "Partitioning Limitations Relating to Functions".

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.1 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see Chapter 18, *Partitioning*.

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.1, all partitions of the same partitioned table must use the same storage engine; for example, you

cannot use `MyISAM` for one partition and `InnoDB` for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the `MERGE` or `CSV` storage engines. Beginning with MySQL 5.1.15, `FEDERATED` tables also cannot be partitioned (Bug #22451). Prior to MySQL 5.1.6, it was also not feasible to create a partitioned table using the `BLACKHOLE` storage engine (Bug #14524). See Section 18.5.2, "Partitioning Limitations Relating to Storage Engines".

Partitioning by `KEY` or `LINEAR KEY` is possible with `NDBCLUSTER`, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an `NDBCLUSTER` table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the `PARTITION BY KEY` or `PARTITION BY LINEAR KEY` clause of the `CREATE TABLE` or `ALTER TABLE` statement used to create or modify a user-partitioned `NDBCLUSTER` table, then the table is not required to have an explicit primary key. For more information, see Section 17.1.6.1, "Noncompliance with SQL Syntax in MySQL Cluster".

To employ a particular storage engine for a partitioned table, it is necessary only to use the `[STORAGE] ENGINE` option just as you would for a nonpartitioned table. However, you should keep in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the `InnoDB` storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
    ENGINE=INNODB
    PARTITION BY HASH( MONTH(tr_date) )
    PARTITIONS 6;
```

Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.1 this has no effect.

> ⚠️ **Important**
>
> Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

Prior to MySQL 5.1.18, these options were permitted even when the `NO_DIR_IN_CREATE` server SQL mode was in effect (Bug #24633).

The `DATA DIRECTORY` and `INDEX DIRECTORY` options have no effect when defining partitions for tables using the `InnoDB` storage engine.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions on Windows. Beginning with MySQL 5.1.24, these options are ignored on Windows, except that a warning is generated (Bug #30459)-

All columns used in the table's partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```
CREATE TABLE tnp (
    id INT NOT NULL AUTO_INCREMENT,
    ref BIGINT NOT NULL,
    name VARCHAR(255),
    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table's primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See Section 18.5.1, "Partitioning Keys, Primary Keys, and Unique Keys", for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. The `MAX_ROWS` option can be useful for causing MySQL Cluster tables to be created with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` data node configuration parameter, as well as Section 17.1.2, "MySQL Cluster Nodes, Node Groups, Replicas, and Partitions", for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.

- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.

- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*, and was implemented in MySQL 5.1.6. For more information, see Section 18.4, "Partition Pruning".

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;`. By "parallelized," we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.

- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as MySQL Partitioning development continues.

18.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.1. These include the types listed here:

- **RANGE partitioning.**   This type of partitioning assigns rows to partitions based on column values falling within a given range. See Section 18.2.1, "RANGE Partitioning".

- **LIST partitioning.**   Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See Section 18.2.2, "LIST Partitioning".

- **HASH partitioning.**   With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See Section 18.2.3, "HASH Partitioning".

- **KEY partitioning.**   This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See Section 18.2.4, "KEY Partitioning".

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.1. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- Section 18.2.1, "RANGE Partitioning"

- Section 18.2.3, "HASH Partitioning"

- Section 18.2.3.1, "LINEAR HASH Partitioning"

For more complex examples of date-based partitioning, see the following sections:

- Section 18.4, "Partition Pruning"

- Section 18.2.5, "Subpartitioning"

MySQL partitioning is optimized for use with the `TO_DAYS()` and `YEAR()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See Section 12.7, "Date and Time Functions", for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with `0`. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered `0`, `1`, `2`, and `3`. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user function employed must return an integer value greater than `0`. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
    -> PARTITION BY LIST(val)(
    ->     PARTITION mypart VALUES IN (1,3,5),
    ->     PARTITION MyPart VALUES IN (2,4,6)
    -> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. (Beginning with MySQL 5.1.12, decimal fractions are no longer truncated, but instead are prohibited entirely.)

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in Section 13.1.17, "CREATE TABLE Syntax".

18.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
```

```
    store_id INT NOT NULL
);
```

Note

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see Section 18.5.1, "Partitioning Keys, Primary Keys, and Unique Keys".

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Mitchell', 'Wilson', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a "catchall" `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

> **Note**
>
> Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see Section 18.2.2, "LIST Partitioning". Also see Section 13.2.5, "INSERT Syntax", for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see Section 18.3, "Partition Management", for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN` (<) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

Beginning with MySQL 5.1.43, it is also possible to partition a table by `RANGE` based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Also beginning with MySQL 5.1.43, any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

> **Note**
>
> It is also possible in MySQL 5.1.43 and later to use `UNIX_TIMESTAMP(timestamp_column)` as a partitioning expression for tables that are partitioned by `LIST`. However, it is usually not practical to do so.

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete "old" data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See Section 13.1.7, "ALTER TABLE Syntax", and Section 18.3, "Partition Management", for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.

- You want to use a column containing date or time values, or containing values arising from some other series.

- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See Section 18.4, "Partition Pruning", for more information about how this is accomplished.

18.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done

by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

> **Note**
>
> In MySQL 5.1, it is possible to match against only a list of integers (and possibly `NULL`—see Section 18.2.6, "How MySQL Partitioning Handles NULL") when partitioning by `LIST`.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 13.1.17, "CREATE TABLE Syntax".

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
);
```

(This is the same table used as a basis for the examples in Section 18.2.1, "RANGE Partitioning".)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LIST(store_id) (
    PARTITION pNorth VALUES IN (3,5,6,9,17),
    PARTITION pEast VALUES IN (1,2,10,11,19,20),
    PARTITION pWest VALUES IN (4,12,13,14,18),
    PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with an `ALTER TABLE employees DROP`

PARTITION pWest statement, which can be executed much more efficiently than the equivalent DELETE statement (DELETE FROM employees WHERE store_id IN (4,12,13,14,18)). However, the ALTER TABLE ... DROP PARTITION statement also removes the partition itself from the definition for the table, and you must execute an ALTER TABLE ... ADD PARTITION statement to restore the table's original partitioning scheme. (This problem is resolved in MySQL 5.5, which adds the ALTER TABLE ... TRUNCATE PARTITION statement for removing all rows from a given partition without affecting the table definition.)

As with RANGE partitioning, it is possible to combine LIST partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Section 18.2.5, "Subpartitioning".

Unlike the case with RANGE partitioning, there is no "catch-all" such as MAXVALUE; all expected values for the partitioning expression should be covered in PARTITION ... VALUES IN (...) clauses. An INSERT statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
    ->   c1 INT,
    ->   c2 INT
    -> )
    -> PARTITION BY LIST(c1) (
    ->   PARTITION p0 VALUES IN (1, 4, 7),
    ->   PARTITION p1 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single INSERT statement the behavior depends on whether the table uses a transactional storage engine. For an InnoDB table, the statement is considered a single transaction, so the presence of any unmatched values causes the statement to fail completely, and no rows are inserted. For a table using a nontransactional storage engine such as MyISAM, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not.

You can cause this type of error to be ignored by using the IGNORE keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values *are* inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5  Duplicates: 2  Warnings: 0

mysql> SELECT * FROM h2;
+------+------+
| c1   | c2   |
+------+------+
|    7 |    5 |
|    1 |    9 |
|    2 |    5 |
+------+------+
3 rows in set (0.00 sec)
```

18.2.3 HASH Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using `HASH` partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where `expr` is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with `PARTITIONS num`, where `num` is a positive integer representing the number of partitions into which the table is to be divided.

> **Note**
>
> For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See Section 18.5.1, "Partitioning Keys, Primary Keys, and Unique Keys", for more information.

The following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to `1`.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for `expr`. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

`expr` must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in Section 18.5, "Restrictions and Limitations on Partitioning". You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise

to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for "pruning" on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce by widely different changes in the value of the expression. For example, changing `int_col` from `5` to `6` produces a change of `-1` in the value of the expression, but changing the value of `int_col` from `6` to `7` produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation $y=cx$ where c is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of *num* partitions to use based on the modulus of the result of the user function. In other words, for an expression *expr*, the partition in which the record is stored is partition number *N*, where *N* = `MOD(`*expr*`, `*num*`)`. Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY HASH( YEAR(col3) )
    PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
=  MOD(2005,4)
=  1
```

MySQL 5.1 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See Section 18.2.3.1, "LINEAR HASH Partitioning", for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

> **Note**
>
> If a table to be partitioned has a `UNIQUE` key, then any columns supplied as arguments to the `HASH` user function or to the `KEY`'s `column_list` must be part of that key.

18.2.3.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression $expr$, the partition in which the record is stored when linear hashing is used is partition number N from among num partitions, where N is derived according to the following algorithm:

1. Find the next power of 2 greater than num. We call this value V; it can be calculated as:

   ```
   V = POWER(2, CEILING(LOG(2, num)))
   ```

   (Suppose that num is 13. Then `LOG(2,13)` is 3.7004397181411. `CEILING(3.7004397181411)` is 4, and V = `POWER(2,4)`, which is 16.)

2. Set N = F($column\_list$) & (V - 1).

3. While N >= num:

   - Set V = CEIL(V / 2)

   - Set N = N & (V - 1)

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY LINEAR HASH( YEAR(col3) )
    PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values `'2003-04-14'` and `'1998-10-19'`. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
```

```
   = 2003 & 7
   = 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6

(6 >= 6 is TRUE: additional step required)

N = 6 & CEILING(8 / 2)
  = 6 & 3
  = 2

(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

18.2.4 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.

- `KEY` takes only a list of one or more column names. Beginning with MySQL 5.1.5, the column or columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one.

  Beginning with MySQL 5.1.6, `KEY` takes a list of zero or more column names. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.6 or later:

```
CREATE TABLE k1 (
    id INT NOT NULL PRIMARY KEY,
    name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

  If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
    id INT NOT NULL,
    name VARCHAR(20),
    UNIQUE KEY (id)
)
PARTITION BY KEY()
```

```
PARTITIONS 2;
```

However, if the unique key column were not defined as NOT NULL, then the previous statement would fail.

In both of these cases, the partitioning key is the id column, even though it is not shown in the output of SHOW CREATE TABLE or in the PARTITION_EXPRESSION column of the INFORMATION_SCHEMA.PARTITIONS table.

Unlike the case with other partitioning types, columns used for partitioning by KEY are not restricted to integer or NULL values. For example, the following CREATE TABLE statement is valid:

```
CREATE TABLE tm1 (
    s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using PARTITION BY KEY() would also be valid and have the same effect as PARTITION BY KEY(s1), since s1 is the table's primary key.)

For additional information about this issue, see Section 18.5, "Restrictions and Limitations on Partitioning".

> **Note**
>
> Also beginning with MySQL 5.1.6, tables using the NDBCLUSTER storage engine are implicitly partitioned by KEY, again using the table's primary key as the partitioning key. In the event that the MySQL Cluster table has no explicit primary key, the "hidden" primary key generated by the NDBCLUSTER storage engine for each MySQL Cluster table is used as the partitioning key.
>
> Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, if you define an explicit partitioning scheme for an NDBCLUSTER table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an "empty" partitioning expression—that is, PARTITION BY KEY() with no column references—then no explicit primary key is required.
>
> You can observe this partitioning using the ndb_desc utility (with the -p option).

> **Important**
>
> For a key-partitioned table using any MySQL storage engine other than NDBCLUSTER, you cannot execute an ALTER TABLE DROP PRIMARY KEY, as doing so generates the error ERROR 1466 (HY000): Field in list of fields for partition function not found in table. This is not an issue for MySQL Cluster tables which are partitioned by KEY; in such cases, the table is reorganized using the "hidden" primary key as the table's new partitioning key. See Chapter 17, *MySQL Cluster NDB 6.1 - 7.1*.

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
```

```
    col1 INT NOT NULL,
    col2 CHAR(5),
    col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using `LINEAR` has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See Section 18.2.3.1, "LINEAR HASH Partitioning", for a description of this algorithm and its implications.

18.2.5 Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
    SUBPARTITIONS 2 (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE
    );
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into `3 * 2 = 6` partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.1, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

> **Note**
>
> `SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see Issues with subpartitions, for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2,
            SUBPARTITION s3
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
```

```
            SUBPARTITION s4,
            SUBPARTITION s5
        )
    );
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.

- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s2,
            SUBPARTITION s3
        )
    );
```

  This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.

- In MySQL 5.1.7 and earlier, names of subpartitions were required to be unique within each partition, but did not have to be unique within the table as a whole. Beginning with MySQL 5.1.8, subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.8 and later:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2,
            SUBPARTITION s3
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4,
            SUBPARTITION s5
        )
    );
```

  (The previous statement is also valid for versions of MySQL prior to 5.1.8.)

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
```

```
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0
                DATA DIRECTORY = '/disk0/data'
                INDEX DIRECTORY = '/disk0/idx',
            SUBPARTITION s1
                DATA DIRECTORY = '/disk1/data'
                INDEX DIRECTORY = '/disk1/idx'
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2
                DATA DIRECTORY = '/disk2/data'
                INDEX DIRECTORY = '/disk2/idx',
            SUBPARTITION s3
                DATA DIRECTORY = '/disk3/data'
                INDEX DIRECTORY = '/disk3/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s5
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        )
    );
```

In this case, a separate disk is used for the data and for the indexes of each `RANGE`. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE(YEAR(purchased))
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0a
                DATA DIRECTORY = '/disk0'
                INDEX DIRECTORY = '/disk1',
            SUBPARTITION s0b
                DATA DIRECTORY = '/disk2'
                INDEX DIRECTORY = '/disk3'
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s1a
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s1b
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s2a,
            SUBPARTITION s2b
        )
    );
```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:

  - The data for subpartition `s0a` is stored on `/disk0`.

  - The indexes for subpartition `s0a` are stored on `/disk1`.

- The data for subpartition `s0b` is stored on `/disk2`.

- The indexes for subpartition `s0b` are stored on `/disk3`.

- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:

    - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4`—the data in `/disk4/data`, and the indexes in `/disk4/idx`.

    - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5`—the data in `/disk5/data`, and the indexes in `/disk5/idx`.

- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

    In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See Section 18.3, "Partition Management", for an explanation of how this can be done.

Beginning with MySQL 5.1.18, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not permitted in partition definitions when the `NO_DIR_IN_CREATE` server SQL mode is in effect. However, this not true when defining subpartitions; this is a known issue which is fixed in MySQL 5.5 (Bug #42954).

18.2.6 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. Beginning with MySQL 5.1.8, the partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

Handling of NULL with RANGE partitioning.   If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. Consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY RANGE(c1) (
    ->     PARTITION p0 VALUES LESS THAN (0),
    ->     PARTITION p1 VALUES LESS THAN (10),
    ->     PARTITION p2 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
    ->     c1 INT,
```

```
    ->      c2 VARCHAR(20)
    -> )
    -> PARTITION BY RANGE(c1) (
    ->      PARTITION p0 VALUES LESS THAN (-5),
    ->      PARTITION p1 VALUES LESS THAN (0),
    ->      PARTITION p2 VALUES LESS THAN (10),
    ->      PARTITION p3 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two CREATE TABLE statements using the following query against the PARTITIONS table in the INFORMATION_SCHEMA database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    >    FROM INFORMATION_SCHEMA.PARTITIONS
    >    WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          0 |              0 |           0 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          0 |              0 |           0 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.00 sec)
```

(For more information about this table, see Section 20.11, "The INFORMATION_SCHEMA PARTITIONS Table".) Now let us populate each of these tables with a single row containing a NULL in the column used as the partitioning key, and verify that the rows were inserted using a pair of SELECT statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against INFORMATION_SCHEMA.PARTITIONS and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    >    FROM INFORMATION_SCHEMA.PARTITIONS
    >    WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
```

```
+-----------+----------------+-----------+----------------+-------------+
| t1        | p0             |         1 |             20 |          20 |
| t1        | p1             |         0 |              0 |           0 |
| t1        | p2             |         0 |              0 |           0 |
| t2        | p0             |         1 |             20 |          20 |
| t2        | p1             |         0 |              0 |           0 |
| t2        | p2             |         0 |              0 |           0 |
| t2        | p3             |         0 |              0 |           0 |
+-----------+----------------+-----------+----------------+-------------+
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the SELECT statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

> **Important**
>
> Prior to MySQL 5.1.8, RANGE partitioning treated a partitioning expression value of NULL as 0 with respect to determining placement. (The only way to circumvent this behavior was to design tables so as not to permit nulls, usually by declaring columns NOT NULL.) If you have a RANGE partitioning scheme that depends on this earlier behavior, you must re-implement it when upgrading to MySQL 5.1.8 or later. (Bug #15447)

NULL is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a CREATE TABLE statement such as this one:

```
CREATE TABLE tndate (
    id INT,
    dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, YEAR(NULL) returns NULL. A row with a dt column value of NULL is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition p0.

Handling of NULL with LIST partitioning. A table that is partitioned by LIST admits NULL values if and only if one of its partitions is defined using that value-list that contains NULL. The converse of this is that a table partitioned by LIST which does not explicitly use NULL in a value list rejects rows resulting in a NULL value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
```

```
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between `0` and `8` inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number `9`. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8),
    ->     PARTITION p3 VALUES IN (NULL)
    -> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7, NULL),
    ->     PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)
```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    >     FROM INFORMATION_SCHEMA.PARTITIONS
    >     WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
```

```
| ts2         | p0              |           0 |               0 |             0 |
| ts2         | p1              |           0 |               0 |             0 |
| ts2         | p2              |           0 |               0 |             0 |
| ts2         | p3              |           1 |              20 |            20 |
| ts3         | p0              |           0 |               0 |             0 |
| ts3         | p1              |           1 |              20 |            20 |
| ts3         | p2              |           0 |               0 |             0 |
+-------------+-----------------+-------------+-----------------+---------------+
7 rows in set (0.01 sec)
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

Handling of NULL with HASH and KEY partitioning.   `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY HASH(c1)
    -> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME,PARTITION_NAME,TABLE_ROWS,AVG_ROW_LENGTH,DATA_LENGTH
    >     FROM INFORMATION_SCHEMA.PARTITIONS
    >     WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME ='th';
+------------+-----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME  | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+-----------------+------------+----------------+-------------+
| th         | p0              |          0 |              0 |           0 |
| th         | p1              |          0 |              0 |           0 |
+------------+-----------------+------------+----------------+-------------+
2 rows in set (0.00 sec)
```

Note that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+------+---------+
| c1   | c2      |
+------+---------+
| NULL | mothra  |
+------+---------+
|    0 | gigan   |
+------+---------+
2 rows in set (0.01 sec)
```

Recall that for any integer N, the value of `NULL MOD` N is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as `0`. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    >    FROM INFORMATION_SCHEMA.PARTITIONS
    >    WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME ='th';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| th         | p0             |          2 |             20 |          20 |
| th         | p1             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
2 rows in set (0.00 sec)
```

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning.

18.3 Partition Management

MySQL 5.1 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement Section 13.1.7, "ALTER TABLE Syntax". There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see Section 18.3.1, "Management of RANGE and LIST Partitions".

- For a discussion of managing `HASH` and `KEY` partitions, see Section 18.3.2, "Management of HASH and KEY Partitions".

- See Section 18.3.4, "Obtaining Information About Partitions", for a discussion of mechanisms provided in MySQL 5.1 for obtaining information about partitioned tables and partitions.

- For a discussion of performing maintenance operations on partitions, see Section 18.3.3, "Maintenance of Partitions".

> **Note**
>
> In MySQL 5.1, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

The statement `ALTER TABLE ... PARTITION BY ...` is available and is functional beginning with MySQL 5.1.6; previously in MySQL 5.1, this was accepted as valid syntax, but the statement did nothing.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (1995),
        PARTITION p2 VALUES LESS THAN (2000),
        PARTITION p3 VALUES LESS THAN (2005)
    );
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

In MySQL 5.1.7 and earlier MySQL 5.1 releases, `ALTER TABLE ... ENGINE = ...` removed all partitioning from the affected table. Beginning with MySQL 5.1.8, this statement changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. As of MySQL 5.1.8, use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See Section 13.1.7, "ALTER TABLE Syntax".

> ⚠️ **Important**
>
> Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITIONS`).

18.3.1 Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Section 18.3.2, "Management of HASH and KEY Partitions". Dropping a `RANGE` or `LIST` partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
    ->     PARTITION BY RANGE( YEAR(purchased) ) (
    ->         PARTITION p0 VALUES LESS THAN (1990),
    ->         PARTITION p1 VALUES LESS THAN (1995),
    ->         PARTITION p2 VALUES LESS THAN (2000),
    ->         PARTITION p3 VALUES LESS THAN (2005)
    ->     );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
    ->     (1, 'desk organiser', '2003-10-15'),
    ->     (2, 'CD player', '1993-11-05'),
    ->     (3, 'TV set', '1996-03-10'),
    ->     (4, 'bookcase', '1982-01-10'),
    ->     (5, 'exercise bike', '2004-05-09'),
    ->     (6, 'sofa', '1987-06-05'),
    ->     (7, 'popcorn maker', '2001-11-22'),
    ->     (8, 'aquarium', '1992-08-04'),
    ->     (9, 'study desk', '1984-09-16'),
    ->     (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
    -> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+------+-----------+------------+
| id   | name      | purchased  |
```

```
+------+-----------+------------+
|    3 | TV set    | 1996-03-10 |
|   10 | lava lamp | 1998-12-25 |
+------+-----------+------------+
2 rows in set (0.00 sec)
```

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

Note

The `NDBCLUSTER` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, the requirement was added in MySQL 5.1.10 that you have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See Section 13.1.34, "TRUNCATE TABLE Syntax".)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in Section 13.1.7, "ALTER TABLE Syntax", for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
*************************** 1. row ***************************
       Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
+------+----------------+------------+
| id   | name           | purchased  |
+------+----------------+------------+
|   11 | pencil holder  | 1995-07-12 |
|    1 | desk organiser | 2003-10-15 |
|    5 | exercise bike  | 2004-05-09 |
|    7 | popcorn maker  | 2001-11-22 |
+------+----------------+------------+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of ALTER TABLE ... DROP PARTITION is not reported by the server as it would be by the equivalent DELETE query.

Dropping LIST partitions uses exactly the same ALTER TABLE ... DROP PARTITION syntax as used for dropping RANGE partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See Section 18.2.2, "LIST Partitioning", for an example.)

To add a new range or list partition to a previously partitioned table, use the ALTER TABLE ... ADD PARTITION statement. For tables which are partitioned by RANGE, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (
    id INT,
    fname VARCHAR(25),
    lname VARCHAR(25),
    dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
    PARTITION p0 VALUES LESS THAN (1970),
    PARTITION p1 VALUES LESS THAN (1980),
    PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the members table to accommodate new members born in the years 1990 to 1999 as shown here:

```
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

With tables that are partitioned by range, you can use ADD PARTITION to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```
mysql> ALTER TABLE members
    >     ADD PARTITION (
    >     PARTITION n VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
```

```
     increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```
ALTER TABLE members
    REORGANIZE PARTITION p0 INTO (
        PARTITION n0 VALUES LESS THAN (1960),
        PARTITION n1 VALUES LESS THAN (1970)
);
```

Using SHOW CREATE TABLE you can see that the ALTER TABLE statement has had the desired effect:

```
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
       Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1960) ENGINE = MyISAM,
 PARTITION n1 VALUES LESS THAN (1970) ENGINE = MyISAM,
 PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
 PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,
 PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM) */
1 row in set (0.00 sec)
```

See also Section 13.1.7.1, "ALTER TABLE Partition Operations".

You can also use ALTER TABLE ... ADD PARTITION to add new partitions to a table that is partitioned by LIST. Suppose a table tt is defined using the following CREATE TABLE statement:

```
CREATE TABLE tt (
    id INT,
    data INT
)
PARTITION BY LIST(data) (
    PARTITION p0 VALUES IN (5, 10, 15),
    PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the data column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new LIST partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
    >       (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
                    in list partitioning
```

Because any rows with the data column value 12 have already been assigned to partition p1, you cannot create a new partition on table tt that includes 12 in its value list. To accomplish this, you could drop p1, and add np and then a new p1 with a modified definition. However, as discussed earlier, this would

result in the loss of all data stored in `p1`—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

Beginning with MySQL 5.1.6, you can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
    PARTITION p5 VALUES LESS THAN (2010),
    PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
       Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM.
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
    PARTITION s0 VALUES LESS THAN (1960),
    PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE` (see Section 13.1.17, "CREATE TABLE Syntax"). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

• The `PARTITION` clauses used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

  Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by `RANGE`) or sets of values (when reorganizing tables partitioned by `LIST`).

> **Note**
>
> Prior to MySQL 5.1.4, you could not reuse the names of existing partitions in the `INTO` clause, even when those partitions were being dropped or redefined. See the Release Notes for MySQL 5.1.4 for more information.

- The combination of partitions in the *partition_definitions* list should account for the same range or set of values overall as the combined partitions named in the *partition_list*.

  For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

  For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table's partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or vice versa. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ....` For example:

```
ALTER TABLE members
    PARTITION BY HASH( YEAR(dob) )
    PARTITIONS 8;
```

18.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 18.3.1, "Management of RANGE and LIST Partitions".

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
    id INT,
    fname VARCHAR(30),
    lname VARCHAR(30),
    signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
    ->      id INT,
    ->      fname VARCHAR(30),
    ->      lname VARCHAR(30),
    ->      signed DATE
    -> )
    -> PARTITION BY LINEAR KEY(signed)
    -> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Note that the number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18. use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

18.3.3 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.1.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables as of MySQL 5.1.27.

Also beginning with MySQL 5.1.27, you can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.**   Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

  Example:

  ```
  ALTER TABLE t1 REBUILD PARTITION p0, p1;
  ```

- **Optimizing partitions.**   If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

  Example:

  ```
  ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
  ```

  Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

Some MySQL storage engines, including `InnoDB`, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` rebuilds the entire table. In MySQL 5.1.68 and later, running this statement on such a table causes the entire table to rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

  Example:

  ```
  ALTER TABLE t1 ANALYZE PARTITION p3;
  ```

- **Repairing partitions.** This repairs corrupted partitions.

  Example:

  ```
  ALTER TABLE t1 REPAIR PARTITION p0,p1;
  ```

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

  Example:

  ```
  ALTER TABLE trb3 CHECK PARTITION p1;
  ```

  This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

> **Note**
>
> The statements `ALTER TABLE ... ANALYZE PARTITION`, `ALTER TABLE ... CHECK PARTITION`, `ALTER TABLE ... OPTIMIZE PARTITION`, and `ALTER TABLE ... REPAIR PARTITION` were originally introduced in MySQL 5.1.5, but did not work properly and were disabled in MySQL 5.1.24. They were re-introduced in MySQL 5.1.27. (Bug #20129) The use of these partitioning-specific `ALTER TABLE` statements with tables which are not partitioned is not supported; beginning with MySQL 5.1.31, it is expressly not permitted. (Bug #39434)
>
> `ALTER TABLE ... REBUILD PARTITION` was also introduced in MySQL 5.1.5.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.

`ANALYZE`, `CHECK`, `OPTIMIZE`, `REBUILD`, `REPAIR`, and `TRUNCATE` operations are not supported for subpartitions.

18.3.4 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.

- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.

- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.

- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
*************************** 1. row ***************************
       Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
```

Note

In early MySQL 5.1 releases, the `PARTITIONS` clause was not shown for tables partitioned by `HASH` or `KEY`. This issue was fixed in MySQL 5.1.6.

`SHOW TABLE STATUS` works with partitioned tables. Beginning with MySQL 5.1.9, its output is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. In MySQL 5.1.8 and earlier, the `Engine` column always contained the value `PARTITION`; beginning with MySQL 5.1.9, this column contains the name of the storage engine used by all partitions of the table. (See Section 13.7.5.38, "SHOW TABLE STATUS Syntax", for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See Section 20.11, "The INFORMATION_SCHEMA PARTITIONS Table".

Beginning with MySQL 5.1.5, it is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` created and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE(id)
    (
        PARTITION p0 VALUES LESS THAN (3),
        PARTITION p1 VALUES LESS THAN (7),
        PARTITION p2 VALUES LESS THAN (9),
        PARTITION p3 VALUES LESS THAN (11)
    );

INSERT INTO trb1 VALUES
    (1, 'desk organiser', '2003-10-15'),
    (2, 'CD player', '1993-11-05'),
    (3, 'TV set', '1996-03-10'),
    (4, 'bookcase', '1982-01-10'),
```

```
    (5, 'exercise bike', '2004-05-09'),
    (6, 'sofa', '1987-06-05'),
    (7, 'popcorn maker', '2001-11-22'),
    (8, 'aquarium', '1992-08-04'),
    (9, 'study desk', '1984-09-16'),
    (10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 10
        Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 10
        Extra: Using where
```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: range
possible_keys: PRIMARY
          key: PRIMARY
      key_len: 4
          ref: NULL
         rows: 7
        Extra: Using where
```

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.

- If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

As of MySQL 5.1.28, the `rows` column of `EXPLAIN PARTITIONS` output always displays the total number of rows in the table. Previously, this was the number of matching rows (see Bug #35745).

See also Section 13.8.2, "EXPLAIN Syntax".

18.4 Partition Pruning

This section discusses an optimization known as *partition pruning*, which was implemented for partitioned tables in MySQL 5.1.6. The core concept behind partition pruning is relatively simple, and can be described as "Do not scan partitions where there can be no matching values". Suppose that you have a partitioned table `t1` defined by this statement:

```
CREATE TABLE t1 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
    PARTITION p0 VALUES LESS THAN (64),
    PARTITION p1 VALUES LESS THAN (128),
    PARTITION p2 VALUES LESS THAN (192),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a query such as this one:

```
SELECT fname, lname, region_code, dob
    FROM t1
    WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in the table. This "cutting away" of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

> **Note**
>
> When pruning is performed on a partitioned `MyISAM` table, all partitions are opened, whether or not they are examined, due to the design of the `MyISAM` storage engine. This means that you must have a sufficient number of file descriptors available to cover all partitions of the table. See MyISAM and partition file descriptor usage.
>
> This limitation does not apply to partitioned tables using other MySQL storage engines such as `InnoDB`.

The query optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- *partition_column = constant*

- *partition_column* IN (*constant1, constant2, ..., constantN*)

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including <, >, <=, >=, and <>. Some queries using BETWEEN in the WHERE clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the WHERE clause can be converted to WHERE region_code IN (126, 127, 128, 129). Then the optimizer can determine that the first two values in the list are found in partition p1, the remaining two values in partition p2, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a DATE or DATETIME column when the partitioning expression uses the YEAR() or TO_DAYS() function.

Suppose that table t2, defined as shown here, is partitioned on a DATE column:

```
CREATE TABLE t2 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
    PARTITION d0 VALUES LESS THAN (1970),
    PARTITION d1 VALUES LESS THAN (1975),
    PARTITION d2 VALUES LESS THAN (1980),
    PARTITION d3 VALUES LESS THAN (1985),
    PARTITION d4 VALUES LESS THAN (1990),
    PARTITION d5 VALUES LESS THAN (2000),
    PARTITION d6 VALUES LESS THAN (2005),
    PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following queries on t2 can make of use partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';

SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last query, the optimizer can also act as follows:

1. *Find the partition containing the low end of the range*.

   YEAR('1984-06-21') yields the value 1984, which is found in partition d3.

2. *Find the partition containing the high end of the range*.

   YEAR('1999-06-21') evaluates to 1999, which is found in partition d5.

3. *Scan only these two partitions and any partitions that may lie between them*.

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

> **Important**
>
> Invalid `DATE` and `DATETIME` values referenced in the `WHERE` clause of a query on a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
    PARTITION r0 VALUES IN (1, 3),
    PARTITION r1 VALUES IN (2, 5, 8),
    PARTITION r2 VALUES IN (4, 9),
    PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `[LINEAR] KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

Any query, such as this one, that compares a column value with a constant can be pruned:

```
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
```

```
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

> **Important**
>
> This optimization is used only if the range size is smaller than the number of partitions. Consider this query:
>
> ```
> SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 12;
> ```
>
> The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the previous query cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this query on table `t4` cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

For a table that is partitioned by `KEY`, has a composite primary key, and uses a composite partitioning key, it is possible to perform pruning for queries meeting the following two criteria:

- The query must have a `WHERE` clause of the form `pkcol1 = c1 AND pkcol2 = c2 AND ... pkcolN = cN`, where `pkcol1` ... `pkcolN` are the partitioning key columns and `c1` ... `cN` are constant values.

- All columns of the partitioning key must be referenced in the `WHERE` clause.

For example, suppose a table named `cities` is created as shown here:

```
CREATE TABLE cities (
    id INT NOT NULL AUTO_INCREMENT,
    name CHAR(35) NOT NULL DEFAULT '',
    country_code CHAR(3) NOT NULL DEFAULT '',
    district CHAR(20) NOT NULL DEFAULT '',
    population INT NOT NULL DEFAULT 0,
    PRIMARY KEY (ID, Population)
)
PARTITION BY KEY ()
PARTITIONS 8;
```

(Note that `PARTITION BY KEY()` is equivalent in this case to `PARTITION BY KEY(id, population)`.)

Only a query that references both the `id` and `population` columns of this table can be pruned, as shown here:

```
mysql> SELECT * FROM cities WHERE id = 101;
+-----+------------+--------------+----------+------------+
| id  | name       | country_code | district | population |
+-----+------------+--------------+----------+------------+
| 101 | Godoy Cruz | ARG          | Mendoza  |     206998 |
+-----+------------+--------------+----------+------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT * FROM cities WHERE population = 206998;
+-----+------------+--------------+----------+------------+
| id  | name       | country_code | district | population |
+-----+------------+--------------+----------+------------+
| 101 | Godoy Cruz | ARG          | Mendoza  |     206998 |
+-----+------------+--------------+----------+------------+
1 row in set (0.00 sec)

mysql> EXPLAIN PARTITIONS SELECT * FROM cities WHERE id = 101\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: cities
   partitions: p0,p1,p2,p3,p4,p5,p6,p7

          ref: const,const
         rows: 1
        Extra:
1 row in set (0.00 sec)
```

This limitation on pruning with composite partitioning keys is removed in MySQL 5.5.

18.5 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

Prohibited constructs.   Beginning with MySQL 5.1.12, the following constructs are not permitted in partitioning expressions:

• Stored procedures, stored functions, UDFs, or plugins.

- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see Section 18.5.3, "Partitioning Limitations Relating to Functions".

Arithmetic and logical operators.   Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter; see Section 18.2, "Partitioning Types", for more information).

Beginning with MySQL 5.1.23, the `DIV` operator is also supported, and the `/` operator is not permitted. (Bug #30188, Bug #33182)

Beginning with MySQL 5.1.12, the bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

HANDLER statements.   In MySQL 5.1, the `HANDLER` statement is not supported with partitioned tables.

Server SQL mode.   Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in Section 5.1.7, "Server SQL Modes", the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables*.

Examples.   The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.**   Suppose that you create a partitioned table whose partitioning expression is one such as *column* `DIV 0` or *column* `MOD 0`, as shown here:

   ```
   mysql> CREATE TABLE tn (c1 INT)
       ->     PARTITION BY LIST(1 DIV c1) (
       ->         PARTITION p0 VALUES IN (NULL),
       ->         PARTITION p1 VALUES IN (1)
       -> );
   Query OK, 0 rows affected (0.05 sec)
   ```

   The default behavior for MySQL is to return `NULL` for the result of a division by zero, without producing any errors:

   ```
   mysql> SELECT @@sql_mode;
   +------------+
   | @@sql_mode |
   +------------+
   |            |
   +------------+
   1 row in set (0.00 sec)

   mysql> INSERT INTO tn VALUES (NULL), (0), (1);
   Query OK, 3 rows affected (0.00 sec)
   Records: 3  Duplicates: 0  Warnings: 0
   ```

   However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same `INSERT` statement to fail, as shown here:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
ERROR 1365 (22012): Division by 0
```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following CREATE TABLE statement can be executed successfully only if the NO_UNSIGNED_SUBTRACTION mode is in effect:

```
mysql> SELECT @@sql_mode;
+------------+
| @@sql_mode |
+------------+
|            |
+------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
    ->   PARTITION BY RANGE(c1 - 10) (
    ->     PARTITION p0 VALUES LESS THAN (-5),
    ->     PARTITION p1 VALUES LESS THAN (0),
    ->     PARTITION p2 VALUES LESS THAN (5),
    ->     PARTITION p3 VALUES LESS THAN (10),
    ->     PARTITION p4 VALUES LESS THAN (MAXVALUE)
    -> );
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-------------------------+
| @@sql_mode              |
+-------------------------+
| NO_UNSIGNED_SUBTRACTION |
+-------------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
    ->   PARTITION BY RANGE(c1 - 10) (
    ->     PARTITION p0 VALUES LESS THAN (-5),
    ->     PARTITION p1 VALUES LESS THAN (0),
    ->     PARTITION p2 VALUES LESS THAN (5),
    ->     PARTITION p3 VALUES LESS THAN (10),
    ->     PARTITION p4 VALUES LESS THAN (MAXVALUE)
    -> );
Query OK, 0 rows affected (0.05 sec)
```

If you remove the NO_UNSIGNED_SUBTRACTION server SQL mode after creating tu, you may no longer be able to access this table:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master's and slave's copies of a given table, and may even cause

inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

Performance considerations. Some affects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table`.

  See also Maximum number of partitions.

- **MyISAM and partition file descriptor usage.** For a partitioned `MyISAM` table, MySQL uses 2 file descriptors for each partition, for each such table that is open. This means that you need many more file descriptors to perform operations on a partitioned `MyISAM` table than on a table which is identical to it except that the latter table is not partitioned, particularly when performing `ALTER TABLE` operations that change the table's partitioning scheme.

  Assume a `MyISAM` table `t` with 100 partitions, such as the table created by this SQL statement:

```
CREATE TABLE t (c1 VARCHAR(50))
PARTITION BY KEY (c1) PARTITIONS 100
ENGINE=MYISAM;
```

> **Note**
>
> For brevity, we use `KEY` partitioning for the table shown in this example, but file descriptor usage as described here applies to all partitioned `MyISAM` tables, regardless of the type of partitioning that is employed. Partitioned tables using other storage engines such as `InnoDB` are not affected by this issue.

  Now assume that you wish to repartition `t` so that it has 101 partitions, using the statement shown here:

```
ALTER TABLE t PARTITION BY KEY (c1) PARTITIONS 101;
```

  To process this `ALTER TABLE` statement, MySQL uses 402 file descriptors—that is, two for each of the 100 original partitions, plus two for each of the 101 new partitions. This is because all partitions (old and new) must be opened concurrently during the reorganization of the table data. It is recommended that, if you expect to perform such operations, you should make sure that `--open-files-limit` is not set too low to accommodate them.

- **Table locks.** The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed.

- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` or `NDB` tables.

- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these

tables to take advantage of *partition pruning* can improve performance dramatically. See Section 18.4, "Partition Pruning", for more information.

- **Performance with LOAD DATA.** Prior to MySQL 5.1.23, `LOAD DATA` performed very poorly when importing into partitioned tables. The statement now uses buffering to improve performance; however, the buffer uses 130 KB memory per partition to achieve this. (Bug #26527)

Maximum number of partitions.

The maximum possible number of partitions for a given table (that does not use the `NDB` storage engine) is 1024. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the `NDBCLUSTER` storage engine is determined according to the version of the MySQL Cluster software being used, the number of data nodes, and other factors. See NDB and user-defined partitioning, for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see Section B.5.2.18, "File Not Found and Similar Errors", for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also File system operations.

Foreign keys not supported for partitioned InnoDB tables.

Partitioned tables using the `InnoDB` storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an `InnoDB` table employing user-defined partitioning may contain foreign key references; no `InnoDB` table whose definition contains foreign key references may be partitioned.

2. No `InnoDB` table definition may contain a foreign key reference to a user-partitioned table; no `InnoDB` table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the `InnoDB` storage engine. `CREATE TABLE` and `ALTER TABLE` statements that would result in tables violating these restrictions are not allowed.

ALTER TABLE ... ORDER BY. An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.

Effects on REPLACE statements by modification of primary keys. It can be desirable in some cases (see Section 18.5.1, "Partitioning Keys, Primary Keys, and Unique Keys") to modify a table's primary key. Be aware that, if your application uses `REPLACE` statements and you do this, the results of these statements can be drastically altered. See Section 13.2.7, "REPLACE Syntax", for more information and an example.

FULLTEXT indexes.

Partitioned tables do not support `FULLTEXT` indexes or searches. This includes partitioned tables employing the `MyISAM` storage engine.

Spatial columns. Columns with spatial data types such as `POINT` or `GEOMETRY` cannot be used in partitioned tables.

Temporary tables.

As of MySQL 5.1.8, temporary tables cannot be partitioned. (Bug #17497)

Log tables.   Beginning with MySQL 5.1.20, it is no longer possible to partition the log tables; beginning with that version, an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error. (Bug #27816)

Data type of partitioning key.
A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing `ENUM` columns cannot be used. The column or expression value may also be `NULL`. (See Section 18.2.6, "How MySQL Partitioning Handles NULL".)

The lone exception to this restriction occurs when partitioning by `[LINEAR] KEY`, it is possible to use columns of any valid MySQL data type other than `TEXT` or `BLOB` as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following two `CREATE TABLE` statements are valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;

CREATE TABLE tke
    ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
PARTITION BY LINEAR KEY(c1)
PARTITIONS 6;
```

Subqueries.
A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.

Issues with subpartitions.
Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

 `SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:

```
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
);
```

You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

```
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
```

```
)
PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```
mysql> CREATE TABLE ts (
    ->     id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->     name VARCHAR(30)
    -> )
    -> PARTITION BY RANGE(id)
    -> SUBPARTITION BY KEY()
    -> SUBPARTITIONS 4
    -> (
    ->     PARTITION p0 VALUES LESS THAN (100),
    ->     PARTITION p1 VALUES LESS THAN (MAXVALUE)
    -> );
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MySQL server version for the right syntax to use near ')

mysql> CREATE TABLE ts (
    ->     id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->     name VARCHAR(30)
    -> )
    -> PARTITION BY RANGE(id)
    -> SUBPARTITION BY KEY(id)
    -> SUBPARTITIONS 4
    -> (
    ->     PARTITION p0 VALUES LESS THAN (100),
    ->     PARTITION p1 VALUES LESS THAN (MAXVALUE)
    -> );
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

Query cache not supported.
The query cache is not supported for partitioned tables. Beginning with MySQL 5.1.63, the query cache is automatically disabled for queries involving partitioned tables, and cannot be enabled for such queries. (Bug #53775)

Key cache not supported.
Caching is not supported for partitioned tables. The `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements, when you attempt to use them on tables having user-defined partitioning, fail with the errors `The storage engine for the table doesn't support assign_to_keycache` and `The storage engine for the table doesn't support preload_keys`, respectively. This issue is fixed in MySQL 5.5.

DELAYED option not supported.   Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Beginning with MySQL 5.1.23, attempting to do so fails with an error (see Bug #31210).

DATA DIRECTORY and INDEX DIRECTORY options.   `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:

- Beginning with MySQL 5.1.23, table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored (see Bug #32091).

- On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions (Bug #30459).

Repairing and rebuilding partitioned tables.   The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables beginning with MySQL 5.1.27. (See Bug #20129.)

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. Both of these statements were added in MySQL 5.1.5. See Section 13.1.7, "ALTER TABLE Syntax", for more information about these two statements.

`mysqlcheck`, `myisamchk`, and `myisampack` are not supported with partitioned tables.

18.5.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1),
    UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
    col1 INT NOT NULL,
```

```
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
    ->     col1 INT NOT NULL,
    ->     col2 DATE NOT NULL,
    ->     col3 INT NOT NULL,
    ->     col4 INT NOT NULL,
    ->     UNIQUE KEY (col1, col2),
    ->     UNIQUE KEY (col3)
    -> )
    -> PARTITION BY HASH(col1 + col3)
    -> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```
mysql> CREATE TABLE t3 (
    ->     col1 INT NOT NULL,
    ->     col2 DATE NOT NULL,
    ->     col3 INT NOT NULL,
    ->     col4 INT NOT NULL,
    ->     UNIQUE KEY (col1, col2, col3),
    ->     UNIQUE KEY (col3)
    -> )
    -> PARTITION BY HASH(col3)
    -> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3),
    UNIQUE KEY (col2, col4)
);
```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t5 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
```

```
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col3),
    UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t7 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col4),
    UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider the partitioned table created as shown here:

```
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
    ->     PARTITION BY RANGE(c1) (
    ->         PARTITION p0 VALUES LESS THAN (10),
    ->         PARTITION p1 VALUES LESS THAN (20),
    ->         PARTITION p2 VALUES LESS THAN (30),
    ->         PARTITION p3 VALUES LESS THAN (40)
    ->     );
Query OK, 0 rows affected (0.12 sec)
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```
#  possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

```
# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0  Duplicates: 0  Warnings: 0

#  use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
#  fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ...
PARTITION BY`. Consider a table `np_pk` created as shown here:

```
mysql> CREATE TABLE np_pk (
    ->     id INT NOT NULL AUTO_INCREMENT,
    ->     name VARCHAR(50),
    ->     added DATE,
    ->     PRIMARY KEY (id)
    -> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```
mysql> ALTER TABLE np_pk
    ->     PARTITION BY HASH( TO_DAYS(added) )
    ->     PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk
    ->     PARTITION BY HASH(id)
    ->     PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

18.5.2 Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

MERGE storage engine.   User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

FEDERATED storage engine.   Partitioning of `FEDERATED` tables is not supported. Beginning with MySQL 5.1.15, it is not possible to create partitioned `FEDERATED` tables at all.

CSV storage engine.   Partitioned tables using the `CSV` storage engine are not supported. Starting with MySQL 5.1.12, it is not possible to create partitioned `CSV` tables at all.

BLACKHOLE storage engine.   Prior to MySQL 5.1.6, tables using the `BLACKHOLE` storage engine also could not be partitioned.

InnoDB storage engine.   `InnoDB` foreign keys and MySQL partitioning are not compatible. Partitioned `InnoDB` tables cannot have foreign key references, nor can they have columns referenced by foreign keys. `InnoDB` tables which have or which are referenced by foreign keys cannot be partitioned.

In addition, `ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use the `InnoDB` storage engine. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see Section 13.1.7.1, "ALTER TABLE Partition Operations".

User-defined partitioning and the NDB storage engine (MySQL Cluster).   Partitioning by `KEY` (including `LINEAR KEY`) is the only type of partitioning supported for the `NDBCLUSTER` storage engine. Beginning with MySQL 5.1.12, it is not possible under normal circumstances to create a MySQL Cluster table using any partitioning type other than [`LINEAR`] `KEY`, and attempting to do so fails with an error.

Exception (not for production): It is possible to override this restriction by setting the `new` system variable on MySQL Cluster SQL nodes to `ON`. If you choose to do this, you should be aware that tables using partitioning types other than [`LINEAR`] `KEY` are not supported in production. *In such cases, you can create and use tables with partitioning types other than `KEY` or `LINEAR KEY`, but you do this entirely at your own risk*.

The maximum number of partitions that can be defined for an `NDBCLUSTER` table depends on the number of data nodes and node groups in the cluster, the version of the MySQL Cluster software in use, and other factors. See NDB and user-defined partitioning, for more information.

The maximum amount of fixed-size data that can be stored per partition in an `NDB` table is 16 GB.

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error (Bug #40709):

1. The table must have an explicit primary key.

2. All columns listed in the table's partitioning expression must be part of the primary key.

Exception.   If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY KEY()` or `PARTITION BY LINEAR KEY()`), then no explicit primary key is required.

Upgrading partitioned tables.   When performing an upgrade, tables which are partitioned by `KEY` and which use any storage engine other than `NDBCLUSTER` must be dumped and reloaded.

Same storage engine for all partitions.   All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not

specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do *not* specify any engine for *any* partition or subpartition

- Specify the engine for *all* partitions or subpartitions

18.5.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Beginning with MySQL 5.1.12, only the MySQL functions allowed in the following table are allowed in partitioning expressions.

`ABS()`	`CEILING()` (see CEILING() and FLOOR())	`DAY()`
`DAYOFMONTH()`	`DAYOFWEEK()`	`DAYOFYEAR()`
`DATEDIFF()`	`EXTRACT()` (see EXTRACT() function with WEEK specifier)	`FLOOR()` (see CEILING() and FLOOR())
`HOUR()`	`MICROSECOND()`	`MINUTE()`
`MOD()`	`MONTH()`	`QUARTER()`
`SECOND()`	`TIME_TO_SEC()`	`TO_DAYS()`
`UNIX_TIMESTAMP()` (permitted in MySQL 5.1.43 and later, with `TIMESTAMP` columns)	`WEEKDAY()`	`YEAR()`
	`YEARWEEK()`	

In MySQL 5.1, range optimization can be used only for the `TO_DAYS()` and `YEAR()` functions. See Section 18.4, "Partition Pruning", for more information.

CEILING() and FLOOR().   Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the `INT` types or `DECIMAL`. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) )(
    ->      PARTITION p0 VALUES IN (1,3,5),
    ->      PARTITION p1 VALUES IN (2,4,6)
    -> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

EXTRACT() function with WEEK specifier.   The value returned by the `EXTRACT()` function, when used as `EXTRACT(WEEK FROM col)`, depends on the value of the `default_week_format` system variable. For this reason, beginning with MySQL 5.1.55, `EXTRACT()` is no longer permitted as a partitioning function when it specifies the unit as `WEEK`. (Bug #54483)

See Section 12.6.2, "Mathematical Functions", for more information about the return types of these functions, as well as Section 11.2, "Numeric Types".

18.5.4 Partitioning and Table-Level Locking

For storage engines such as `MyISAM` that actually execute table-level locks when executing DML or DDL statements, such a statement affecting a partitioned table imposes a lock on the table as a whole; that

is, all partitions are locked until the statement was finished. For example, a `SELECT` from a partitioned `MyISAM` table causes a lock on the entire table.

In practical terms, what this means is that the statements discussed later in this section tend to execute more slowly as the number of partitions increases. This limitation is greatly reduced in MySQL 5.6, with the introduction of *partition lock pruning* in MySQL 5.6.6.

This is not true for statements effecting partitioned tables using storage engines such as `InnoDB`, that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning.

The next few paragraphs discuss the effects of MySQL statements on partitioned tables using storage engines that employ table-level locks.

DML statements

`SELECT` statements lock the entire table. `SELECT` statements containing unions or joins lock all tables named in the union or join.

`UPDATE` also locks the entire table.

`REPLACE` and `INSERT` (including `INSERT ... ON DUPLICATE KEY UPDATE`) lock the entire table.

`INSERT ... SELECT` locks both the source table and the target table.

> **Note**
>
> `INSERT DELAYED` is not supported for partitioned tables.

A `LOAD DATA` statement on a partitioned table locks the entire table.

A trigger on a partitioned table, once activated, locks the entire table.

DDL statements

`CREATE VIEW` causes a lock on any partitioned table from which it reads.

`ALTER TABLE` locks the affected partitioned table.

Other statements

`LOCK TABLES` locks all partitions of a partioned table.

Evaluating the `expr` in a `CALL stored_procedure(expr)` statement locks all partitions of any partitioned table referenced by `expr`.

`ALTER TABLE` also takes a metadata lock on the table level.

Chapter 19 Stored Programs and Views

Table of Contents

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation.

- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.

- Events. An event is a task that the server runs according to schedule.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See Section 13.1, "Data Definition Statements".

- The `CALL` statement is used to invoke stored procedures. See Section 13.2.1, "CALL Syntax".

- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See Section 13.6, "MySQL Compound-Statement Syntax".

19.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`;`) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
    -> BEGIN
    ->   SET @x = 0;
    ->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+------+
| @x   |
+------+
| 1001 |
+------+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash ("\") character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
```

```
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

19.2 Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.1. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See Section 4.4.8, "`mysql_upgrade` — Check and Upgrade MySQL Tables".

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.

- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

Additional Resources

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.

- For answers to some commonly asked questions regarding stored routines in MySQL, see Section A.4, "MySQL 5.1 FAQ: Stored Procedures and Functions".

- There are some restrictions on the use of stored routines. See Section C.1, "Restrictions on Stored Programs".

- Binary logging for stored routines takes place as described in Section 19.7, "Binary Logging of Stored Programs".

19.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 13.1.15, "CREATE PROCEDURE and CREATE FUNCTION Syntax"). A procedure is invoked using a `CALL` statement (see Section 13.2.1, "CALL Syntax"), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see Section 13.6, "MySQL Compound-Statement Syntax").

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 13.1.26, "DROP PROCEDURE and DROP FUNCTION Syntax"), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 13.1.5, "ALTER PROCEDURE Syntax").

A stored procedure or function is associated with a particular database. This has several implications:
