The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `'@'localhost` enables clients to connect as an anonymous user from the local host with any user name. In this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| user1@localhost | @localhost     |
+-----+-----+
```

The host name part of an account can contain wildcards, too. If the host name contains a `'%'` or `'_'` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value will not indicate which one. For example, the account `'user2'@'%.example.com'` can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| user2@remote.example.com | user2@%.example.com |
+-----+-----+
```

If an application must invoke `USER()` for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` value with an account in the `user` table, it is necessary to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not permit `User` to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in `Host` values. All accounts must have a nonempty `User` value and literal `Host` value.

With respect to the previous examples, the `'@'localhost` and `'user2'@'%.example.com'` accounts should be changed not to use wildcards:

```
RENAME USER '@'localhost TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` or `USER()` value, use the `SUBSTRING_INDEX()` function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', 1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', 1) |
+-----+
| user1                                     |
+-----+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', -1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', -1) |
+-----+
| localhost                                 |
+-----+
```

6.3 Using Encrypted Connections

With an unencrypted connection between the MySQL client and the server, someone with access to the network could watch all your traffic and inspect the data being sent or received between client and server.

When you must move information over a network in a secure fashion, an unencrypted connection is unacceptable. To make any kind of data unreadable, use encryption. Encryption algorithms must include security elements to resist many kinds of known attacks such as changing the order of encrypted messages or replaying data twice.

MySQL supports encrypted connections between clients and the server using the TLS (Transport Layer Security) protocol. TLS is sometimes referred to as SSL (Secure Sockets Layer) but MySQL does not actually use the SSL protocol for encrypted connections because its encryption is weak (see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#)).

TLS uses encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect data change, loss, or replay. TLS also incorporates algorithms that provide identity verification using the X.509 standard.

X.509 makes it possible to identify someone on the Internet. In basic terms, there should be some entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can present the certificate to another party as proof of identity. A certificate consists of its owner’s public key. Any data encrypted using this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

MySQL can be compiled for encrypted-connection support using OpenSSL or yaSSL. For a comparison of the two packages, see [Section 6.3.4, “SSL Library-Dependent Capabilities”](#). For information about the encryption protocols and ciphers each package supports, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

MySQL programs attempt to connect using encryption if the proper options are given and the server supports encrypted connections. For information about options that affect use of encrypted connections, see [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#) and [Command Options for Encrypted Connections](#).

MySQL performs encryption on a per-connection basis, and use of encryption for a given user can be optional or mandatory. This enables you to choose an encrypted or unencrypted connection according to the requirements of individual applications. For information on how to require users to use encrypted connections, see the discussion of the `REQUIRE` clause of the `GRANT` statement in [Section 13.7.1.3, “GRANT Statement”](#).

Encrypted connections are not used by default. For applications that require the security provided by encrypted connections, the extra computation to encrypt the data is worthwhile.

Encrypted connections can be used between master and slave replication servers. See [Section 17.3.7, “Setting Up Replication to Use Encrypted Connections”](#).

For information about using encrypted connections from the MySQL C API, see [Section 23.7.14, “C API Encrypted Connection Support”](#).

It is also possible to connect using encryption from within an SSH connection to the MySQL server host. For an example, see [Section 6.3.5, “Connecting to MySQL Remotely from Windows with SSH”](#).

6.3.1 Configuring MySQL to Use Encrypted Connections

To enable encrypted connections, your MySQL distribution must be built with SSL support, as described in [Section 2.9.6, “Configuring SSL Library Support”](#). In addition, several options are available to indicate whether to use encrypted connections, and to specify the appropriate certificate and key files. This section provides general guidance about configuring the server and clients for encrypted connections:

- [Server-Side Startup Configuration for Encrypted Connections](#)
- [Client-Side Configuration for Encrypted Connections](#)

For a complete list of options related to establishment of encrypted connections, see [Command Options for Encrypted Connections](#). To create any [Command Options for Encrypted Connections](#). Instructions for creating any required certificate and key files are available in [Section 6.3.3, “Creating SSL Certificates and Keys Using openssl”](#).

Encrypted connections also can be used in these contexts:

- Between master and slave replication servers. See [Section 17.3.7, “Setting Up Replication to Use Encrypted Connections”](#).
- By client programs that are based on the MySQL C API. See [Section 23.7.14, “C API Encrypted Connection Support”](#).

Note

If the server is compiled against OpenSSL, clients from MySQL 5.5 versions older than 5.5.37 are not able to connect to the server using encrypted connections if the client library is compiled using yaSSL. Either use a client and server compiled using the same SSL package, or upgrade to clients compiled against a client library version from MySQL 5.5.37 or higher.

Server-Side Startup Configuration for Encrypted Connections

These options on the server side specify the certificate and key files the server uses when permitting clients to establish encrypted connections:

- `--ssl-ca`: The path name of the Certificate Authority (CA) certificate file. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)
- `--ssl-cert`: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.
- `--ssl-key`: The path name of the server private key file.

For example, to enable the server for encrypted connections, start it with these lines in the `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=ca.pem
ssl-cert=server-cert.pem
```

```
ssl-key=server-key.pem
```

Each certificate and key option names a file in PEM format. If you have a MySQL source distribution, you can test your setup using the demonstration certificate and key files in its `mysql-test/std_data` directory.

The values of the `--ssl-xxx` options set the values of the corresponding system variables (`ssl_ca`, `ssl_cert`, `ssl_key`, and so forth).

Client-Side Configuration for Encrypted Connections

These options on the client side identify the certificate and key files clients use when establishing encrypted connections to the server. They are similar to the options used on the server side, but `--ssl-cert` and `--ssl-key` identify the client public and private key:

- `--ssl-ca`: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)
- `--ssl-cert`: The path name of the client public key certificate file.
- `--ssl-key`: The path name of the client private key file.

For additional security relative to that provided by the default encryption, clients can supply a CA certificate matching the one used by the server and enable host name identity verification. In this way, the server and client place their trust in the same CA certificate and the client verifies that the host to which it connected is the one intended:

- To specify the CA certificate, use `--ssl-ca` (or `--ssl-capath`).
- To enable host name identity verification as well, specify `--ssl-verify-server-cert`.
- To require an encrypted connection, specify `--ssl-mode=REQUIRED`.

Depending on the encryption requirements of the MySQL account used by a client, the client may be required to specify certain options to connect using encryption to the MySQL server.

Suppose that you want to connect using an account that has no special encryption requirements or that was created using a `GRANT` statement that included the `REQUIRE SSL` clause. As a recommended set of encrypted-connection options, start the server with at least `--ssl-cert` and `--ssl-key`, and invoke the client with `--ssl-ca` (or `--ssl-capath`). A client can connect using encryption like this:

```
mysql --ssl-ca=ca.pem
```

To require that a client certificate also be specified, create the account using a `REQUIRE X509` clause. Then the client must also specify the proper client key and certificate files or the server will reject the connection:

```
mysql --ssl-ca=ca.pem \
      --ssl-cert=client-cert.pem \
      --ssl-key=client-key.pem
```

For additional information about the `REQUIRE` clause, see [Section 13.7.1.3, “GRANT Statement”](#).

To prevent use of encryption and override other `--ssl-xxx` options, invoke the client program with `--ssl=0` or a synonym (`--skip-ssl`, `--disable-ssl`):

```
mysql --ssl=0
```

To determine whether the current connection with the server uses encryption, check the session value of the `Ssl_cipher` status variable. If the value is empty, the connection is not encrypted. Otherwise, the connection is encrypted and the value indicates the encryption cipher. For example:

```
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+-----+-----+
| Variable_name | Value |
+-----+-----+
```

```
+-----+
| Ssl_cipher | DHE-RSA-AES256-SHA |
+-----+
```

For the `mysql` client, an alternative is to use the `STATUS` or `\s` command and check the `SSL` line:

```
mysql> \s
...
SSL: Not in use
...
```

Or:

```
mysql> \s
...
SSL: Cipher in use is DHE-RSA-AES256-SHA
...
```

6.3.2 Encrypted Connection TLS Protocols and Ciphers

MySQL supports TLS encryption, and enables configuring which ciphers to permit for encrypted connections. It is also possible to determine which TLS protocol and cipher the current session uses.

- [Supported Connection TLS Protocols](#)
- [Connection Cipher Configuration](#)
- [Monitoring Current Session TLS Protocol and Cipher](#)

Supported Connection TLS Protocols

MySQL supports encrypted connections using the TLSv1 protocol. As of MySQL 5.5.42, SSL 2.0 and SSL 3.0 are explicitly disabled because they provide weak encryption.

Connection Cipher Configuration

A default set of ciphers applies to encrypted connections, which can be overridden by explicitly configuring the permitted ciphers. During connection establishment, both sides of a connection must permit some cipher in common or the connection fails. Of the permitted ciphers common to both sides, the SSL library chooses the one supported by the provided certificate that has the highest priority.

To specify a cipher or ciphers for encrypted connections, use the `--ssl-cipher` option, which is available for the server and for client programs.

For master/slave replication, the `MASTER_SSL_CIPHER` option for the `CHANGE MASTER TO` statement specifies which ciphers a slave server permits for connections to the master.

To determine which ciphers a given server supports, check the session value of the `Ssl_cipher_list` status variable:

```
SHOW SESSION STATUS LIKE 'Ssl_cipher_list';
```

The `Ssl_cipher_list` status variable lists the possible SSL ciphers (empty for non-SSL connections). The set of available ciphers depends on your MySQL version and whether MySQL was compiled using OpenSSL or yaSSL, and (for OpenSSL) the library version used to compile MySQL.

MySQL passes a default cipher list to the SSL library.

MySQL passes this default cipher list to OpenSSL:

```
AES256-GCM-SHA384
AES256-SHA
AES256-SHA256
CAMELLIA256-SHA
DES-CBC3-SHA
DHE-DSS-AES256-GCM-SHA384
DHE-DSS-AES256-SHA
DHE-DSS-AES256-SHA256
```

```
DHE-DSS-CAMELLIA256-SHA
DHE-RSA-AES256-GCM-SHA384
DHE-RSA-AES256-SHA
DHE-RSA-AES256-SHA256
DHE-RSA-CAMELLIA256-SHA
ECDH-ECDSA-AES256-GCM-SHA384
ECDH-ECDSA-AES256-SHA
ECDH-ECDSA-AES256-SHA384
ECDH-ECDSA-DES-CBC3-SHA
ECDH-RSA-AES256-GCM-SHA384
ECDH-RSA-AES256-SHA
ECDH-RSA-AES256-SHA384
ECDH-RSA-DES-CBC3-SHA
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES128-SHA
ECDHE-ECDSA-AES128-SHA256
ECDHE-ECDSA-AES256-GCM-SHA384
ECDHE-ECDSA-AES256-SHA
ECDHE-ECDSA-AES256-SHA384
ECDHE-ECDSA-DES-CBC3-SHA
ECDHE-RSA-AES128-GCM-SHA256
ECDHE-RSA-AES128-SHA
ECDHE-RSA-AES128-SHA256
ECDHE-RSA-AES256-GCM-SHA384
ECDHE-RSA-AES256-SHA
ECDHE-RSA-AES256-SHA384
ECDHE-RSA-DES-CBC3-SHA
EDH-DSS-DES-CBC3-SHA
EDH-RSA-DES-CBC3-SHA
PSK-3DES-EDE-CBC-SHA
PSK-AES256-CBC-SHA
SRP-DSS-3DES-EDE-CBC-SHA
SRP-DSS-AES-128-CBC-SHA
SRP-DSS-AES-256-CBC-SHA
SRP-RSA-3DES-EDE-CBC-SHA
SRP-RSA-AES-128-CBC-S
SRP-RSA-AES-256-CBC-SHA
```

MySQL passes this default cipher list to yaSSL:

```
AES128-RMD
AES128-SHA
AES256-RMD
AES256-SHA
DES-CBC-SHA
DES-CBC3-RMD
DES-CBC3-SHA
DHE-RSA-AES128-RMD
DHE-RSA-AES128-SHA
DHE-RSA-AES256-RMD
DHE-RSA-AES256-SHA
DHE-RSA-DES-CBC3-RMD
EDH-RSA-DES-CBC-SHA
EDH-RSA-DES-CBC3-SHA
RC4-MD5
RC4-SHA
```

Monitoring Current Session TLS Protocol and Cipher

To determine which encryption TLS protocol and cipher the current session uses, check the session values of the `Ssl_version` and `Ssl_cipher` status variables:

```
mysql> SHOW SESSION STATUS LIKE 'Ssl_version';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ssl_version   | TLSv1 |
+-----+-----+
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+-----+-----+
| Variable_name | Value |
+-----+-----+
```

```
| Ssl_cipher | DHE-RSA-AES256-SHA |
+-----+-----+
```

If the connection is not encrypted, both variables have an empty value.

6.3.3 Creating SSL Certificates and Keys Using openssl

This section describes how to use the `openssl` command to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

Important

Whatever method you use to generate the certificate and key files, the Common Name value used for the server and client certificates/keys must each differ from the Common Name value used for the CA certificate. Otherwise, the certificate and key files will not work for servers compiled using OpenSSL. A typical error in this case is:

```
ERROR 2026 (HY000): SSL connection error:
error:00000001:lib(0):func(0):reason(1)
```

- [Example 1: Creating SSL Files from the Command Line on Unix](#)
- [Example 2: Creating SSL Files Using a Script on Unix](#)
- [Example 3: Creating SSL Files on Windows](#)

Example 1: Creating SSL Files from the Command Line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to respond to several prompts by the `openssl` commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```
# Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts

# Create CA certificate
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 3600 \
    -key ca-key.pem -out ca.pem

# Create server certificate, remove passphrase, and sign it
# server-cert.pem = public key, server-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout server-key.pem -out server-req.pem
openssl rsa -in server-key.pem -out server-key.pem
openssl x509 -req -in server-req.pem -days 3600 \
    -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

# Create client certificate, remove passphrase, and sign it
# client-cert.pem = public key, client-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout client-key.pem -out client-req.pem
openssl rsa -in client-key.pem -out client-key.pem
openssl x509 -req -in client-req.pem -days 3600 \
    -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem
```

After generating the certificates, verify them:

```
openssl verify -CAfile ca.pem server-cert.pem client-cert.pem
```

You should see a response like this:

```
server-cert.pem: OK
client-cert.pem: OK
```

Now you have a set of files that can be used as follows:

- `ca.pem`: Use this as the argument to `--ssl-ca` on the server and client sides. (The CA certificate, if used, must be the same on both sides.)
- `server-cert.pem`, `server-key.pem`: Use these as the arguments to `--ssl-cert` and `--ssl-key` on the server side.
- `client-cert.pem`, `client-key.pem`: Use these as the arguments to `--ssl-cert` and `--ssl-key` on the client side.

For additional usage instructions, see [Section 6.3.1, "Configuring MySQL to Use Encrypted Connections"](#).

Example 2: Creating SSL Files Using a Script on Unix

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files for SSL connections as described in [Section 6.3.1, "Configuring MySQL to Use Encrypted Connections"](#).

```
DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
# directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
# Generation of Certificate Authority(CA)
#

openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca.pem \
    -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/finley/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# .....++++++
# .....++++++
# writing new private key to '/home/finley/openssl/private/cakey.pem'

ssl-key=$DIR/server-key.pem

```

EOF

Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

<http://www.slproweb.com/products/Win32OpenSSL.html>

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location will be `C:\OpenSSL-Win32` or `C:\OpenSSL-Win64`, depending on which package you downloaded. The following instructions assume a default location of `C:\OpenSSL-Win32`. Modify this as necessary if you are using the 64-bit package.

If a message occurs during setup indicating `'...critical component is missing: Microsoft Visual C++ 2008 Redistributables'`, cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=9B2DA534-3E03-4391-8A4D-074B9F2BC1BF>

- Visual C++ 2008 Redistributables (x64), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=bd2a6171-e2d6-4230-b809-9a8d7548c1b6>

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default `C:\OpenSSL-Win32` as the install path, and also leave the default option `'Copy OpenSSL DLL files to the Windows system directory'` selected.

When the installation has finished, add `C:\OpenSSL-Win32\bin` to the Windows System Path variable of your server:

1. On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
2. Select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
3. Under **System Variables**, select **Path**, then click the **Edit** button. The **Edit System Variable** dialogue should appear.
4. Add `;C:\OpenSSL-Win32\bin` to the end (notice the semicolon).
5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (`Start>Run>cmd.exe`) and verifying that OpenSSL is available (depending on your version of Windows, the following path-setting instructions might differ slightly):

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.

C:\Windows\system32>cd \

C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.

C:\>
```

After OpenSSL has been installed, use instructions similar to those from Example 1 (shown earlier in this section), with the following changes:

- Change the following Unix commands:

```
# Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts
```

On Windows, use these commands instead:

```
# Create clean environment
md c:\newcerts
cd c:\newcerts
```

- When a `'\'` character is shown at the end of a command line, this `'\'` character must be removed and the command lines entered all on a single line.

After generating the certificate and key files, to use them for SSL connections, see [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

6.3.4 SSL Library-Dependent Capabilities

MySQL can be compiled using OpenSSL or yaSSL, both of which enable encrypted connections based on the OpenSSL API:

- MySQL Enterprise Edition binary distributions are compiled using yaSSL.
- MySQL Community Edition binary distributions are compiled using yaSSL.
- MySQL Community Edition source distributions can be compiled using either OpenSSL or yaSSL (see [Section 2.9.6, “Configuring SSL Library Support”](#)).

OpenSSL and yaSSL offer the same basic functionality, but additional features are available in MySQL distributions compiled using OpenSSL:

- OpenSSL supports a more flexible syntax for specifying ciphers for the `--ssl-cipher` option, and supports a wider range of encryption ciphers from which to choose. See [Command Options for Encrypted Connections](#), and [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).
- OpenSSL supports the `--ssl-capath` option. MySQL distributions compiled using yaSSL do not because yaSSL does not look in any directory and do not follow a chained certificate tree. yaSSL requires that all components of the CA certificate tree be contained within a single CA certificate tree and that each certificate in the file has a unique SubjectName value. To work around this limitation, concatenate the individual certificate files comprising the certificate tree into a new file and specify that file as the value of the `--ssl-ca` option.

6.3.5 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get an encrypted connection to a remote MySQL server with SSH. The information was provided by David Carlson <dcarlson@mplcomm.com>.

1. Install an SSH client on your Windows machine. For a comparison of SSH clients, see http://en.wikipedia.org/wiki/Comparison_of_SSH_clients.
2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306`, `remote_host: yourmysqlservername_or_ip`, `remote_port: 3306`) or a local forward (Set `port: 3306`, `host: localhost`, `remote port: 3306`).
4. Save everything, otherwise you will have to redo it the next time.
5. Log in to your server with the SSH session you just created.

6. On your Windows machine, start some ODBC application (such as Access).
7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

6.4 Security Plugins

MySQL includes several plugins that implement security features:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. For general discussion of the authentication process, see [Section 6.2.10, “Pluggable Authentication”](#). For characteristics of specific authentication plugins, see [Section 6.4.1, “Authentication Plugins”](#).
- (MySQL Enterprise Edition only) MySQL Enterprise Audit, implemented using a server plugin, uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines. See [Section 6.4.2, “MySQL Enterprise Audit”](#).

6.4.1 Authentication Plugins

The following sections describe pluggable authentication methods available in MySQL and the plugins that implement these methods. For general discussion of the authentication process, see [Section 6.2.10, “Pluggable Authentication”](#).

6.4.1.1 Native Pluggable Authentication

MySQL includes two plugins that implement native authentication; that is, authentication based on the password hashing methods in use from before the introduction of pluggable authentication. This section describes `mysql_native_password`, which implements authentication against the `mysql.user` system table using the native password hashing method. For information about `mysql_old_password`, which implements authentication using the older (pre-4.1) native password hashing method, see [Section 6.4.1.2, “Old Native Pluggable Authentication”](#). For information about these password hashing methods, see [Section 6.1.2.4, “Password Hashing in MySQL”](#).

The `mysql_native_password` native authentication plugin is backward compatible. Older clients that do not support authentication *plugins* do use the native authentication *protocol*, so they can connect to servers that support pluggable authentication.

The following table shows the plugin names on the server and client sides.

Table 6.8 Plugin and Library Names for Native Password Authentication

| Plugin or File | Plugin or File Name |
|--------------------|------------------------------------|
| Server-side plugin | <code>mysql_native_password</code> |
| Client-side plugin | <code>mysql_native_password</code> |
| Library file | None (plugins are built in) |

The following sections provide installation and usage information specific to native pluggable authentication:

- [Installing Native Pluggable Authentication](#)
- [Using Native Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.10, “Pluggable Authentication”](#).

Installing Native Pluggable Authentication

The `mysql_native_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

Using Native Pluggable Authentication

MySQL client programs use `mysql_native_password` by default. The `--default-auth` option can be used as a hint about which client-side plugin the program can expect to use:

```
shell> mysql --default-auth=mysql_native_password ...
```

If an account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.

6.4.1.2 Old Native Pluggable Authentication

MySQL includes two plugins that implement native authentication; that is, authentication based on the password hashing methods in use from before the introduction of pluggable authentication. This section describes `mysql_old_password`, which implements authentication against the `mysql.user` system table using the older (pre-4.1) native password hashing method. For information about `mysql_native_password`, which implements authentication using the native password hashing method, see [Section 6.4.1.1, “Native Pluggable Authentication”](#). For information about these password hashing methods, see [Section 6.1.2.4, “Password Hashing in MySQL”](#).

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided.

The `mysql_old_password` native authentication plugin is backward compatible. Older clients that do not support authentication *plugins* do use the native authentication *protocol*, so they can connect to servers that support pluggable authentication.

The following table shows the plugin names on the server and client sides.

Table 6.9 Plugin and Library Names for Old Native Password Authentication

| Plugin or File | Plugin or File Name |
|--------------------|---------------------------------|
| Server-side plugin | <code>mysql_old_password</code> |
| Client-side plugin | <code>mysql_old_password</code> |
| Library file | None (plugins are built in) |

The following sections provide installation and usage information specific to old native pluggable authentication:

- [Installing Old Native Pluggable Authentication](#)
- [Using Old Native Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.10, “Pluggable Authentication”](#).

Installing Old Native Pluggable Authentication

The `mysql_old_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

Using Old Native Pluggable Authentication

MySQL client programs can use the `--default-auth` option to specify the `mysql_old_password` plugin as a hint about which client-side plugin the program can expect to use:

```
shell> mysql --default-auth=mysql_old_password ...
```

If an account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.

6.4.1.3 Client-Side Cleartext Pluggable Authentication

As of MySQL 5.5.10, a client-side authentication plugin is available that enables clients to send passwords to the server as cleartext, without hashing or encryption. This plugin is built into the MySQL client library.

The following table shows the plugin name.

Table 6.10 Plugin and Library Names for Cleartext Authentication

| Plugin or File | Plugin or File Name |
|--------------------|-----------------------------------|
| Server-side plugin | None, see discussion |
| Client-side plugin | <code>mysql_clear_password</code> |
| Library file | None (plugin is built in) |

Many client-side authentication plugins perform hashing or encryption of a password before the client sends it to the server. This enables clients to avoid sending passwords as cleartext.

Hashing or encryption cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the client-side `mysql_clear_password` plugin is used to send the password to the server as cleartext. There is no corresponding server-side plugin. Rather, the client-side plugin can be used by any server-side plugin that needs a cleartext

Hashing or encryption cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the client-side `mysql_clear_password` plugin is used, which enables the client to send the password to the server as cleartext. There is no corresponding server-side plugin. Rather, `mysql_clear_password` can be used on the client side in concert with any server-side plugin that needs a cleartext password. (The PAM authentication plugin is one such; see [Section 6.4.1.4, “PAM Pluggable Authentication”](#).)

The following discussion provides usage information specific to cleartext pluggable authentication. For general information about pluggable authentication in MySQL, see [Section 6.2.10, “Pluggable Authentication”](#).

**Note**

Sending passwords as cleartext may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects the password. Possibilities include SSL (see [Section 6.3, “Using Encrypted Connections”](#)), IPsec, or a private network.

As of MySQL 5.5.27, to make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it. This can be done in several ways:

- Set the `LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN` environment variable to a value that begins with `1`, `Y`, or `y`. This enables the plugin for all client connections.
- The `mysql`, `mysqladmin`, and `mysqlslap` client programs (also `mysqlcheck`, `mysqldump`, and `mysqlshow` for MySQL 5.5.47 and later) support an `--enable-cleartext-plugin` option that enables the plugin on a per-invocation basis.
- The `mysql_options()` C API function supports a `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option that enables the plugin on a per-connection basis. Also, any program that uses `libmysqlclient` and reads option files can enable the plugin by including an `enable-cleartext-plugin` option in an option group read by the client library.

6.4.1.4 PAM Pluggable Authentication

**Note**

PAM pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

As of MySQL 5.5.16, MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as traditional Unix passwords or an LDAP directory.

PAM pluggable authentication provides these capabilities:

- External authentication: PAM authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables and that authenticate using methods supported by PAM.
- Proxy user support: PAM authentication can return to MySQL a user name different from the external user name passed by the client program, based on the PAM groups the external user is a member of and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, an operating system user named `joe` can connect and have the privileges of a MySQL user named `developer`.

PAM pluggable authentication has been tested on Linux and macOS.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable. For installation information, see [Installing PAM Pluggable Authentication](#).

Table 6.11 Plugin and Library Names for PAM Authentication

| Plugin or File | Plugin or File Name |
|--------------------|-----------------------------------|
| Server-side plugin | <code>authentication_pam</code> |
| Client-side plugin | <code>mysql_clear_password</code> |

| Plugin or File | Plugin or File Name |
|----------------|------------------------------------|
| Library file | <code>authentication_pam.so</code> |

As of MySQL 5.5.10, the client-side `mysql_clear_password` cleartext plugin that communicates with the server-side PAM plugin is built into the `libmysqlclient` client library and is included in all distributions, including community distributions. Inclusion of the client-side cleartext plugin in all MySQL distributions enables clients from any distribution to connect to a server that has the server-side PAM plugin loaded.

The following sections provide installation and usage information specific to PAM pluggable authentication:

- [How PAM Authentication of MySQL Users Works](#)
- [Installing PAM Pluggable Authentication](#)
- [Uninstalling PAM Pluggable Authentication](#)
- [Using PAM Pluggable Authentication](#)
- [PAM Unix Password Authentication without Proxy Users](#)
- [PAM LDAP Authentication without Proxy Users](#)
- [PAM Unix Password Authentication with Proxy Users and Group Mapping](#)
- [PAM Authentication Access to Unix Password Store](#)
- [PAM Authentication Debugging](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.10, “Pluggable Authentication”](#). For information about the `mysql_clear_password` plugin, see [Section 6.4.1.3, “Client-Side Cleartext Pluggable Authentication”](#). For proxy user information, see [Section 6.2.11, “Proxy Users”](#).

How PAM Authentication of MySQL Users Works

This section provides a general overview of how MySQL and PAM work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific PAM services, see [Using PAM Pluggable Authentication](#).

1. The client program and the server communicate, with the client sending to the server the client user name (the operating system user name by default) and password:
 - The client user name is the external user name.
 - For accounts that use the PAM server-side authentication plugin, the corresponding client-side plugin is `mysql_clear_password`. This client-side plugin performs no password hashing, with the result that the client sends the password to the server as cleartext.
2. The server finds a matching MySQL account based on the external user name and the host from which the client connects. The PAM plugin uses the information passed to it by MySQL Server (such as user name, host name, password, and authentication string). When you define a MySQL account that authenticates using PAM, the authentication string contains:
 - A PAM service name, which is a name that the system administrator can use to refer to an authentication method for a particular application. There can be multiple applications associated with a single database server instance, so the choice of service name is left to the SQL application developer.
 - Optionally, if proxying is to be used, a mapping from PAM groups to MySQL user names.

3. The plugin uses the PAM service named in the authentication string to check the user credentials and returns 'Authentication succeeded, Username is user_name' or 'Authentication failed'. The password must be appropriate for the password store used by the PAM service. Examples:

- For traditional Unix passwords, the service looks up passwords stored in the `/etc/shadow` file.
- For LDAP, the service looks up passwords stored in an LDAP directory.

If the credentials check fails, the server refuses the connection.

4. Otherwise, the authentication string indicates whether proxying occurs. If the string contains no PAM group mapping, proxying does not occur. In this case, the MySQL user name is the same as the external user name.

5. Otherwise, proxying is indicated based on the PAM group mapping, with the MySQL user name determined based on the first matching group in the mapping list. The meaning of “PAM group” depends on the PAM service. Examples:

- For traditional Unix passwords, groups are Unix groups defined in the `/etc/group` file, possibly supplemented with additional PAM information in a file such as `/etc/security/group.conf`.
- For LDAP, groups are LDAP groups defined in an LDAP directory.

If the proxy user (the external user) has the `PROXY` privilege for the proxied MySQL user name, proxying occurs, with the proxy user assuming the privileges of the proxied user.

Installing PAM Pluggable Authentication

This section describes how to install the PAM authentication plugin. For general information about installing plugins, see [Section 5.5.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `authentication_pam`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load=authentication_pam.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN authentication_pam SONAME 'authentication_pam.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.5.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
```

```
WHERE PLUGIN_NAME LIKE '%pam%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| authentication_pam | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the PAM plugin, see [Using PAM Pluggable Authentication](#).

Uninstalling PAM Pluggable Authentication

The method used to uninstall the PAM authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_pam;
```

Using PAM Pluggable Authentication

This section describes in general terms how to use the PAM authentication plugin to connect from MySQL client programs to the server. The following sections provide instructions for using PAM authentication in specific ways. It is assumed that the server is running with the server-side PAM plugin enabled, as described in [Installing PAM Pluggable Authentication](#), and that client programs are recent enough to include the client-side plugin.

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_pam`. For example:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'auth_string';
```

The authentication string specifies the following types of information:

- The PAM service name (see [How PAM Authentication of MySQL Users Works](#)). Examples in the following discussion use a service name of `mysql-unix` for authentication using traditional Unix passwords, and `mysql-ldap` for authentication using LDAP.
- For proxy support, PAM provides a way for a PAM module to return to the server a MySQL user name other than the external user name passed by the client program when it connects to the server. Use the authentication string to control the mapping from external user names to MySQL user names. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.

For example, if an account uses the `mysql-unix` PAM service name and should map operating system users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL users, respectively, use a statement like this:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'mysql-unix, root=developer, users=data_entry';
```

Authentication string syntax for the PAM authentication plugin follows these rules:

- The string consists of a PAM service name, optionally followed by a PAM group mapping list consisting of one or more keyword/value pairs each specifying a PAM group name and a MySQL user name:

```
pam_service_name[ ,pam_group_name=mysql_user_name]...
```

The plugin parses the authentication string for each connection attempt that uses the account. To minimize overhead, keep the string as short as possible.

- Each `pam_group_name=mysql_user_name` pair must be preceded by a comma.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `pam_service_name`, `pam_group_name`, and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `pam_service_name`, `pam_group_name`, or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (`\`). To include either character, escape it with a backslash.

If the plugin successfully authenticates the external user name (the name passed by the client), it looks for a PAM group mapping list in the authentication string and, if present, uses it to return a different MySQL user name to the MySQL server based on which PAM groups the external user is a member of:

- If the authentication string contains no PAM group mapping list, the plugin returns the external name.
- If the authentication string does contain a PAM group mapping list, the plugin examines each `pam_group_name=mysql_user_name` pair in the list from left to right and tries to find a match for the `pam_group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `mysql_user_name` for the first match it finds. If the plugin finds no match for any PAM group, it returns the external name. If the plugin is not capable of looking up a group in a directory, it ignores the PAM group mapping list and returns the external name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

- No proxy users. This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication. (For a MySQL account of `'user_name'@'host_name'` to match the external user, `user_name` must be the external user name and `host_name` must match the host from which the client connects.) Authentication can be performed by various PAM-supported methods. Later discussion shows how to authenticate client credentials using traditional Unix passwords, and passwords in LDAP.

PAM authentication, when not done through proxy users or PAM groups, requires the MySQL user name to be same as the operating system user name. MySQL user names are limited to 16 characters (see [Section 6.2.3, "Grant Tables"](#)), which limits PAM nonproxy authentication to Unix accounts with names of at most 16 characters.

- Proxy users only, with PAM group mapping. For this scenario, create one or more MySQL accounts that define different sets of privileges. (Ideally, nobody should connect using those accounts directly.) Then define a default user authenticating through PAM that uses some mapping scheme (usually based on the external PAM groups the users are members of) to map all the external user names to the few MySQL accounts holding the privilege sets. Any client who connects and specifies an external user name as the client user name is mapped to one of the MySQL accounts and uses its privileges. The discussion shows how to set this up using traditional Unix passwords, but other PAM methods such as LDAP could be used instead.

Variations on these scenarios are possible:

- You can permit some users to log in directly (without proxying) but require others to connect through proxy accounts.
- You can use one PAM authentication method for some users, and another method for other users, by using differing PAM service names among your PAM-authenticated accounts. For example, you can use the `mysql-unix` PAM service for some users, and `mysql-ldap` for others.

The examples make the following assumptions. You might need to make some adjustments if your system is set up differently.

- The login name and password are `antonio` and `antonio_password`, respectively. Change these to correspond to the user you want to authenticate.
- The PAM configuration directory is `/etc/pam.d`.
- The PAM service name corresponds to the authentication method (`mysql-unix` or `mysql-ldap` in this discussion). To use a given PAM service, you must set up a PAM file with the same name in the PAM configuration directory (creating the file if it does not exist). In addition, you must use the PAM service name in the authentication string of `CREATE USER` or `GRANT` statements for any account that authenticates using that service.

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set in the server's startup environment. If so, the plugin enables logging of diagnostic messages to the standard output. Depending on how your server is started, the message might appear on the console or in the error log. These messages can be helpful for debugging PAM-related issues that occur when the plugin performs authentication. For more information, see [PAM Authentication Debugging](#).

PAM Unix Password Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and Unix passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through traditional Unix password store.

Note

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see [PAM Authentication Access to Unix Password Store](#).

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.
2. Set up PAM to authenticate MySQL connections using traditional Unix passwords by creating a `mysql-unix` PAM service file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

```
##PAM-1.0
auth            include            password-auth
account         include            password-auth
```

For macOS, use `login` rather than `password-auth`.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
@include common-account
@include common-session-noninteractive
```

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-unix` PAM service:

```
CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-unix';
GRANT ALL PRIVILEGES
  ON mydb.*
```

```
TO 'antonio'@'localhost';
```

Here, the authentication string contains only the PAM service name, `mysql-unix`, which authenticates Unix passwords.

4. Use the `mysql` command-line client to connect to the MySQL server as `antonio`. For example:

```
shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password
```

The server should permit the connection and the following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | antonio@localhost | NULL          |
+-----+-----+-----+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `antonio` MySQL user, and that no proxying has occurred.

Note

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See [Section 6.4.1.3, “Client-Side Cleartext Pluggable Authentication”](#).
- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

PAM LDAP Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and LDAP passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through LDAP.

To use PAM LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the PAM LDAP service to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.

Configure MySQL for PAM LDAP authentication as follows:

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.
2. Set up PAM to authenticate MySQL connections using LDAP by creating a `mysql-ldap` PAM service file named `/etc/pam.d/mysql-ldap`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-ldap` file might look like this:

```

#%PAM-1.0
auth      required      pam_ldap.so
account   required      pam_ldap.so

```

If PAM object files have a suffix different from `.so` on your system, substitute the correct suffix.

The PAM file format might differ on some systems.

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-ldap` PAM service:

```

CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-ldap';
GRANT ALL PRIVILEGES
  ON mydb.*
  TO 'antonio'@'localhost';

```

Here, the authentication string contains only the PAM service name, `mysql-ldap`, which authenticates using LDAP.

4. Connecting to the server is the same as described in [PAM Unix Password Authentication without Proxy Users](#).

PAM Unix Password Authentication with Proxy Users and Group Mapping

The authentication scheme described here uses proxying and PAM group mapping to map connecting MySQL users who authenticate using PAM onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy account authenticated using PAM, such that all the external users are mapped to the MySQL accounts that hold the privileges. Any user who connects using the proxy account is mapped to one of those MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of [PAM LDAP Authentication without Proxy Users](#).

Note

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see [PAM Authentication Access to Unix Password Store](#).

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.
2. Verify that `antonio` is a member of the `root` or `users` PAM group.
3. Set up PAM to authenticate the `mysql-unix` PAM service through operating system users by creating a file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

```

#%PAM-1.0
auth      include      password-auth
account   include      password-auth

```

For macOS, use `login` rather than `password-auth`.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
```

```
@include common-account
@include common-session-noninteractive
```

4. Create a default proxy user (`'@'`) that maps external PAM users to the proxied accounts:

```
CREATE USER '@'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-unix, root=developer, users=data_entry';
```

Here, the authentication string contains the PAM service name, `mysql-unix`, which authenticates Unix passwords. The authentication string also maps external users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL user names, respectively.

The PAM group mapping list following the PAM service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to perform mapping from external user names to the proper proxied MySQL user names.

Note

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

5. Create the proxied accounts and grant to them the privileges required for MySQL access:

```
CREATE USER 'developer'@'localhost'
  IDENTIFIED BY 'very secret password';
CREATE USER 'data_entry'@'localhost'
  IDENTIFIED BY 'very secret password';

GRANT ALL PRIVILEGES
  ON mydevdb.*
  TO 'developer'@'localhost';
GRANT ALL PRIVILEGES
  ON mydb.*
  TO 'data_entry'@'localhost';
```

If you do not let anyone know the passwords for these accounts, clients cannot use them to connect directly to the MySQL server. Instead, it is expected that users who authenticate using PAM will use the `developer` or `data_entry` account by proxy based on their PAM group.

6. Grant to the proxy account the `PROXY` privilege for each proxied account:

```
GRANT PROXY
  ON 'developer'@'localhost'
  TO '@';
GRANT PROXY
  ON 'data_entry'@'localhost'
  TO '@';
```

7. Use the `mysql` command-line client to connect to the MySQL server as `antonio`.

```
shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password
```

The server authenticates the connection using the default `'@'` proxy account. The resulting privileges for `antonio` depend on which PAM groups `antonio` is a member of. If `antonio` is a member of the `root` PAM group, the PAM plugin maps `root` to the `developer` MySQL user name and returns that name to the server. The server verifies that `'@'` has the `PROXY` privilege for `developer` and permits the connection. The following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | developer@localhost | '@' |
+-----+-----+-----+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `developer` MySQL user, and that proxying occurs through the default proxy account.

If `antonio` is not a member of the `root` PAM group but is a member of the `users` PAM group, a similar process occurs, but the plugin maps `user` PAM group membership to the `data_entry` MySQL user name and returns that name to the server:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | data_entry@localhost | ''@'' |
+-----+-----+-----+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges of the `data_entry` MySQL user, and that proxying occurs through the default proxy account.

Note

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See [Section 6.4.1.3, “Client-Side Cleartext Pluggable Authentication”](#).
- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

PAM Authentication Access to Unix Password Store

On some systems, Unix authentication uses a password store such as `/etc/shadow`, a file that typically has restricted access permissions. This can cause MySQL PAM-based authentication to fail. Unfortunately, the PAM implementation does not permit distinguishing “password could not be checked” (due, for example, to inability to read `/etc/shadow`) from “password does not match.” If you are using Unix password store for PAM authentication, you may be able to enable access to it from MySQL using one of the following methods:

- Assuming that the MySQL server is run from the `mysql` operating system account, put that account in the `shadow` group that has `/etc/shadow` access:

1. Create a `shadow` group in `/etc/group`.
2. Add the `mysql` operating system user to the `shadow` group in `/etc/group`.
3. Assign `/etc/group` to the `shadow` group and enable the group read permission:

```
chgrp shadow /etc/shadow
chmod g+r /etc/shadow
```

4. Restart the MySQL server.

- If you are using the `pam_unix` module and the `unix_chkpwd` utility, enable password store access as follows:

```
chmod u-s /usr/sbin/unix_chkpwd
setcap cap_dac_read_search+ep /usr/sbin/unix_chkpwd
```

Adjust the path to `unix_chkpwd` as necessary for your platform.

PAM Authentication Debugging

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set (the value does not matter). If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related issues that occur when the plugin performs authentication.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.

Another technique for debugging connection failures and determining what is happening during connection attempts is to configure PAM authentication to permit all connections, then check the system log files. This technique should be used only on a *temporary* basis, and not on a production server.

Configure a PAM service file named `/etc/pam.d/mysql-any-password` with these contents (the format may differ on some systems):

```
##PAM-1.0
auth      required    pam_permit.so
account   required    pam_permit.so
```

Create an account that uses the PAM plugin and names the `mysql-any-password` PAM service:

```
CREATE USER 'testuser'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-any-password';
```

The `mysql-any-password` service file causes any authentication attempt to return true, even for incorrect passwords. If an authentication attempt fails, that tells you the configuration problem is on the MySQL side. Otherwise, the problem is on the operating system/PAM side. To see what might be happening, check system log files such as `/var/log/secure`, `/var/log/audit.log`, `/var/log/syslog`, or `/var/log/messages`.

After determining what the problem is, remove the `mysql-any-password` PAM service file to disable any-password access.

6.4.1.5 Windows Pluggable Authentication

Note

Windows pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

As of MySQL 5.5.16, MySQL Enterprise Edition for Windows supports an authentication method that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the Windows OS. This identity includes the name of the client account. Windows pluggable authentication uses the identity of the client to check whether it is a given account or a member of a group. By default, negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

Windows pluggable authentication provides these capabilities:

- External authentication: Windows authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables who have logged in to Windows.
- Proxy user support: Windows authentication can return to MySQL a user name different from the external user name passed by the client program. This means that the plugin can return the MySQL user that defines the privileges the external Windows-authenticated user should have. For example, a Windows user named `joe` can connect and have the privileges of a MySQL user named `developer`.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.

Table 6.12 Plugin and Library Names for Windows Authentication

| Plugin or File | Plugin or File Name |
|--------------------|--|
| Server-side plugin | <code>authentication_windows</code> |
| Client-side plugin | <code>authentication_windows_client</code> |
| Library file | <code>authentication_windows.dll</code> |

The library file includes only the server-side plugin. As of MySQL 5.5.13, the client-side plugin is built into the `libmysqlclient` client library.

The server-side Windows authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This permits clients from any 5.5.13 or higher distribution to connect to a server that has the server-side plugin loaded.

The Windows authentication plugin is supported on any version of Windows supported by MySQL 5.5 (see <https://www.mysql.com/support/supportedplatforms/database.html>). It requires MySQL Server 5.5.16 or higher.

The following sections provide installation and usage information specific to Windows pluggable authentication:

- [Installing Windows Pluggable Authentication](#)
- [Uninstalling Windows Pluggable Authentication](#)
- [Using Windows Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.10, “Pluggable Authentication”](#). For proxy user information, see [Section 6.2.11, “Proxy Users”](#).

Installing Windows Pluggable Authentication

This section describes how to install the Windows authentication plugin. For general information about installing plugins, see [Section 5.5.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load=authentication_windows.dll
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN authentication_windows SONAME 'authentication_windows.dll';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.5.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%windows%';
+-----+-----+
| PLUGIN_NAME          | PLUGIN_STATUS |
+-----+-----+
| authentication_windows | ACTIVE        |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the Windows authentication plugin, see [Using Windows Pluggable Authentication](#). Additional plugin control is provided by the `authentication_windows_use_principal_name` and `authentication_windows_log_level` system variables. See [Section 5.1.7, “Server System Variables”](#).

Uninstalling Windows Pluggable Authentication

The method used to uninstall the Windows authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_windows;
```

In addition, remove any startup options that set Windows plugin-related system variables.

Using Windows Pluggable Authentication

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server is running with the server-side plugin enabled, as described in [Installing Windows Pluggable Authentication](#), and that client programs are recent enough to include the client-side plugin built into `libmysqlclient` (MySQL 5.5.13 or higher). Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_windows`. Suppose that the Windows users `Rafal` and `Tasha` should be permitted to connect to MySQL, as well as any users in the `Administrators` or `Power Users` group. To set this up, create a MySQL account named `sql_admin` that uses the Windows plugin for authentication:

```
CREATE USER sql_admin
IDENTIFIED WITH authentication_windows
AS 'Rafal, Tasha, Administrators, "Power Users"';
```

The plugin name is `authentication_windows`. The string following the `AS` keyword is the authentication string. It specifies that the Windows users named `Rafal` or `Tasha` are permitted to authenticate to the server as the MySQL user `sql_admin`, as are any Windows users in the `Administrators` or `Power Users` group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the `sql_admin` account, a user who has logged in to Windows can attempt to connect to the server using that account:

```
C:\> mysql --user=sql_admin
```

No password is required here. The `authentication_windows` plugin uses the Windows security API to check which Windows user is connecting. If that user is named `Rafal` or `Tasha`, or is a member of the `Administrators` or `Power Users` group, the server grants access and the client is authenticated as `sql_admin` and has whatever privileges are granted to the `sql_admin` account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:

- The string consists of one or more user mappings separated by commas.
- Each user mapping associates a Windows user or group name with a MySQL user name:

```
win_user_or_group_name=mysql_user_name
win_user_or_group_name
```

For the latter syntax, with no `mysql_user_name` value given, the implicit value is the MySQL user created by the `CREATE USER` statement. Thus, these statements are equivalent:

```
CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal, Tasha, Administrators, "Power Users"';

CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin,
     "Power Users"=sql_admin';
```

- Each backslash character (`\`) in a value must be doubled because backslash is the escape character in MySQL strings.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `win_user_or_group_name` and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `win_user_or_group_name` and or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.
- `win_user_or_group_name` values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

```
domain\\user
.\\user
domain\\group
.\\group
BUILTIN\\WellKnownGroup
```

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding `mysql_user_name` to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named `win_user` is a member of `win_group` and the authentication string looks like this:

```
'win_group = sql_user1, win_user = sql_user2'
```

When `win_user` connects to the MySQL server, there is a match both to `win_group` and to `win_user`. The plugin authenticates the user as `sql_user2` because the more-specific user match

takes precedence over the group match, even though the group is listed first in the authentication string.

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Windows Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting
  IDENTIFIED WITH authentication_windows
  AS 'SomeDomain\\Accounting';
```

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see [Section 6.2.11, “Proxy Users”](#)). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The `local_user` and `MyDomain\domain_user` local and domain Windows users should map to the `local_wlad` MySQL account.
- Users in the `MyDomain\Developers` domain group should map to the `local_dev` MySQL account.
- Local machine administrators should map to the `local_admin` MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (`local_wlad`, `local_dev`, `local_admin`). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:

```
CREATE USER win_proxy
  IDENTIFIED WITH authentication_windows
  AS 'local_user = local_wlad,
     MyDomain\\domain_user = local_wlad,
     MyDomain\\Developers = local_dev,
     BUILTIN\\Administrators = local_admin';
```

2. For proxying to work, the proxied accounts must exist, so create them:

```
CREATE USER local_wlad IDENTIFIED BY 'secret_wlad_pass';
CREATE USER local_dev IDENTIFIED BY 'secret_dev_pass';
CREATE USER local_admin IDENTIFIED BY 'secret_admin_pass';
```

If you do not let anyone know the passwords for these accounts, clients cannot use them to connect directly to the MySQL server. Instead, it is expected that users who authenticate using Windows will use the `win_proxy` proxy account.

You should also execute `GRANT` statements (not shown) that grant each proxied account the privileges required for MySQL access.

3. Grant to the proxy account the `PROXY` privilege for each proxied account:

```
GRANT PROXY ON local_wlad TO win_proxy;
GRANT PROXY ON local_dev TO win_proxy;
GRANT PROXY ON local_admin TO win_proxy;
```

Now the Windows users `local_user` and `MyDomain\domain_user` can connect to the MySQL server as `win_proxy` and when authenticated have the privileges of the account given in the

authentication string (in this case, `local_wlad`). A user in the `MyDomain\Developers` group who connects as `win_proxy` has the privileges of the `local_dev` account. A user in the `BUILTIN\Administrators` group has the privileges of the `local_admin` account.

To configure authentication so that all Windows users who do not have their own MySQL account go through a proxy account, substitute the default proxy account (`'@'`) for `win_proxy` in the preceding instructions. For information about default proxy accounts, see [Section 6.2.11, “Proxy Users”](#).

Note

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

To use the Windows authentication plugin with Connector/NET connection strings in Connector/NET 6.4.4 and higher, see [Using the Windows Native Authentication Plugin](#).

6.4.1.6 Socket Peer-Credential Pluggable Authentication

As of MySQL 5.5.10, a server-side `auth_socket` authentication plugin is available that authenticates clients that connect from the local host through the Unix socket file. The plugin uses the `SO_PEERCREC` socket option to obtain information about the user running the client program. Thus, the plugin can be used only on systems that support the `SO_PEERCREC` option, such as Linux.

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.

Table 6.13 Plugin and Library Names for Socket Peer-Credential Authentication

| Plugin or File | Plugin or File Name |
|--------------------|-----------------------------|
| Server-side plugin | <code>auth_socket</code> |
| Client-side plugin | None, see discussion |
| Library file | <code>auth_socket.so</code> |

The following sections provide installation and usage information specific to socket pluggable authentication:

- [Installing Socket Pluggable Authentication](#)
- [Uninstalling Socket Pluggable Authentication](#)
- [Using Socket Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.10, “Pluggable Authentication”](#).

Installing Socket Pluggable Authentication

This section describes how to install the socket authentication plugin. For general information about installing plugins, see [Section 5.5.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load=auth_socket.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN auth_socket SONAME 'auth_socket.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.5.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
        FROM INFORMATION_SCHEMA.PLUGINS
        WHERE PLUGIN_NAME LIKE '%socket%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| auth_socket | ACTIVE        |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the socket plugin, see [Using Socket Pluggable Authentication](#).

Uninstalling Socket Pluggable Authentication

The method used to uninstall the socket authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN auth_socket;
```

Using Socket Pluggable Authentication

The socket plugin checks whether the socket user name (the operating system user name) matches the MySQL user name specified by the client program to the server, and permits the connection only if the names match.

Suppose that a MySQL account is created for an operating system user named `valerie` who is to be authenticated by the `auth_socket` plugin for connections from the local host through the socket file:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
```

If a user on the local host with a login name of `stefanie` invokes `mysql` with the option `--user=valerie` to connect through the socket file, the server uses `auth_socket` to authenticate the client. The plugin determines that the `--user` option value (`valerie`) differs from the client user's name (`stefanie`) and refuses the connection. If a user named `valerie` tries the same thing, the plugin finds that the user name and the MySQL user name are both `valerie` and permits the connection. However, the plugin refuses the connection even for `valerie` if the connection is made using a different protocol, such as TCP/IP.

6.4.1.7 Test Pluggable Authentication

MySQL includes a test plugin that checks account credentials and logs success or failure to the server error log. This is a loadable plugin (not built in) and must be installed prior to use.

The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

Note

This plugin is intended for testing and development purposes, and is not for use in production environments or on servers that are exposed to public networks.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable.

Table 6.14 Plugin and Library Names for Test Authentication

| Plugin or File | Plugin or File Name |
|--------------------|----------------------------------|
| Server-side plugin | <code>test_plugin_server</code> |
| Client-side plugin | <code>auth_test_plugin</code> |
| Library file | <code>auth_test_plugin.so</code> |

The following sections provide installation and usage information specific to test pluggable authentication:

- [Installing Test Pluggable Authentication](#)
- [Uninstalling Test Pluggable Authentication](#)
- [Using Test Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 6.2.10, “Pluggable Authentication”](#).

Installing Test Pluggable Authentication

This section describes how to install the test authentication plugin. For general information about installing plugins, see [Section 5.5.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load=auth_test_plugin.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.5.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
```

```
WHERE PLUGIN_NAME LIKE '%test_plugin%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| test_plugin_server | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the test plugin, see [Using Test Pluggable Authentication](#).

Uninstalling Test Pluggable Authentication

The method used to uninstall the test authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN test_plugin_server;
```

Using Test Pluggable Authentication

To use the test authentication plugin, create an account and name that plugin in the `IDENTIFIED WITH` clause:

```
CREATE USER 'testuser'@'localhost' IDENTIFIED WITH test_plugin_server;
SET PASSWORD FOR 'testuser'@'localhost' = PASSWORD('testpassword');
```

Then provide the `--user` and `--password` options for that account when you connect to the server. For example:

```
shell> mysql --user=testuser --password
Enter password: testpassword
```

The plugin fetches the password as received from the client and compares it with the value stored in the `authentication_string` column of the account row in the `mysql.user` system table. If the two values match, the plugin returns the `authentication_string` value as the new effective user ID.

You can look in the server error log for a message indicating whether authentication succeeded (notice that the password is reported as the “user”):

```
[Note] Plugin test_plugin_server reported:
'successfully authenticated user testpassword'
```

6.4.2 MySQL Enterprise Audit

Note

MySQL Enterprise Audit is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

As of MySQL 5.5.28, MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

After you install the plugin (see [Section 6.4.2.1, “Installing MySQL Enterprise Audit”](#)), it writes an audit log file. By default, the file is named `audit.log` in the server data directory. To change the name of the file, set the `audit_log_file` system variable at server startup.

Audit log file contents are not encrypted. See [Section 6.4.2.2, “MySQL Enterprise Audit Security Considerations”](#).

The audit log file is written in XML, with auditable events encoded as `<AUDIT_RECORD>` elements. To select the file format, set the `audit_log_format` system variable at server startup. For details on file format and contents, see [Section 6.4.2.3, “Audit Log File Formats”](#).

To control what information the audit log plugin writes to its log file, set the `audit_log_policy` system variable. By default, this variable is set to `ALL` (write all auditable events), but also permits values of `LOGINS` or `QUERIES` to log only login or query events, or `NONE` to disable logging.

For more information about controlling how logging occurs, see [Section 6.4.2.4, “Audit Log Logging Control”](#). For descriptions of the parameters used to configure the audit log plugin, see [Section 6.4.2.7, “Audit Log Options and System Variables”](#).

If the audit log plugin is enabled, the Performance Schema (see [Chapter 22, MySQL Performance Schema](#)) has instrumentation for it. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE '%/alog/%';
```

Changes from Older MySQL Enterprise Audit Versions

Several changes were made to the audit log plugin in MySQL 5.5.34 for better compatibility with Oracle Audit Vault.

MySQL 5.7 changed audit log file output to a new format. This format has been backported to MySQL 5.5 and it is possible to select either the old or new format using the `audit_log_format` system variable, which has permitted values of `OLD` and `NEW` (default `OLD`). The two formats differ as follows:

- Information within `<AUDIT_RECORD>` elements written in the old format using attributes is written in the new format using subelements.
- The new format includes more information in `<AUDIT_RECORD>` elements. Every element includes a `RECORD_ID` value providing a unique identifier. The `TIMESTAMP` value includes time zone information. Query records include `HOST`, `IP`, `OS_LOGIN`, and `USER` information, as well as `COMMAND_CLASS` and `STATUS_CODE` values.

Example of old `<AUDIT_RECORD>` format:

```
<AUDIT_RECORD
  TIMESTAMP="2013-09-15T15:27:27"
  NAME="Query"
  CONNECTION_ID="3"
  STATUS="0"
  SQLTEXT="SELECT 1"
/>
```

Example of new `<AUDIT_RECORD>` format:

```
<AUDIT_RECORD>
  <TIMESTAMP>2013-09-15T15:27:27 UTC</TIMESTAMP>
  <RECORD_ID>3998_2013-09-15T15:27:27</RECORD_ID>
  <NAME>Query</NAME>
  <CONNECTION_ID>3</CONNECTION_ID>
  <STATUS>0</STATUS>
  <STATUS_CODE>0</STATUS_CODE>
  <USER>root[root] @ localhost [127.0.0.1]</USER>
  <OS_LOGIN></OS_LOGIN>
  <HOST>localhost</HOST>
  <IP>127.0.0.1</IP>
  <COMMAND_CLASS>select</COMMAND_CLASS>
  <SQLTEXT>SELECT 1</SQLTEXT>
```

```
</AUDIT_RECORD>
```

When the audit log plugin rotates the audit log file, it uses a different file name format. For a log file named `audit.log`, the plugin previously renamed the file to `audit.log.TIMESTAMP`. The plugin now renames the file to `audit.log.TIMESTAMP.xml` to indicate that it is an XML file.

If you change the value of `audit_log_format`, use this procedure to avoid writing log entries in one format to an existing log file that contains entries in a different format:

1. Stop the server.
2. Rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin will create a new log file, which will contain log entries in the selected format.

The API for writing audit plugins has also changed. The `mysql_event_general` structure has new members to represent client host name and IP address, command class, and external user. For more information, see [Section 24.2.4.8, “Writing Audit Plugins”](#).

6.4.2.1 Installing MySQL Enterprise Audit

This section describes how to install MySQL Enterprise Audit, which is implemented using the `audit_log` plugin. For general information about installing plugins, see [Section 5.5.1, “Installing and Uninstalling Plugins”](#).

Note

If installed, the `audit_log` plugin involves some minimal overhead even when disabled. To avoid this overhead, do not install MySQL Enterprise Audit unless you plan to use it.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `audit_log`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put the following lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load=audit_log.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN audit_log SONAME 'audit_log.so';
```

`INSTALL PLUGIN` loads the plugin, and also registers it in the `mysql.plugins` system table to cause the plugin to be loaded for each subsequent normal server startup without the need for `--plugin-load`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.5.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
        FROM INFORMATION_SCHEMA.PLUGINS
        WHERE PLUGIN_NAME LIKE 'audit%';
+-----+-----+
```

| PLUGIN_NAME | PLUGIN_STATUS |
|-------------|---------------|
| audit_log | ACTIVE |

If the plugin failed to initialize, check the server error log for diagnostic messages.

If the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load`, you can use the `--audit-log` option at server startup to control plugin activation. For example, to load the plugin at startup and prevent it from being removed at runtime, use these options:

```
[mysqld]
plugin-load=audit_log.so
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use `--audit-log` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

For additional information about the parameters used to configure operation of the `audit_log` plugin, see [Section 6.4.2.7, “Audit Log Options and System Variables”](#).

Audit log file contents are not encrypted. See [Section 6.4.2.2, “MySQL Enterprise Audit Security Considerations”](#).

6.4.2.2 MySQL Enterprise Audit Security Considerations

Contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. The default file name is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` system variable at server startup. Other audit log files may exist due to log rotation.

6.4.2.3 Audit Log File Formats

The MySQL server calls the audit log plugin to write an audit record to its log file whenever an auditable event occurs. Typically the first audit record written after plugin startup contains the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA` are not logged.

To select the log format that the audit log plugin uses to write its log file, set the `audit_log_format` system variable at server startup. These formats are available:

- New-style XML format (`audit_log_format=NEW`): An XML format that has better compatibility with Oracle Audit Vault than old-style XML format. MySQL 5.7 introduced this format, which was backported to MySQL 5.5 as of MySQL 5.5.34.
- Old-style XML format (`audit_log_format=OLD`): The original audit log format used by default in older MySQL series. MySQL 5.5 uses old-style XML format by default.

Note

Changing the value of `audit_log_format` can result in writing log entries in one format to an existing log file that contains entries in a different format. To avoid this issue, use the procedure described at [Audit Log File Format](#).

Audit log file contents are not encrypted. See [Section 6.4.2.2, “MySQL Enterprise Audit Security Considerations”](#).

The following sections describe the available audit logging formats:

- [New-Style XML Audit Log File Format](#)

- [Old-Style XML Audit Log File Format](#)

New-Style XML Audit Log File Format

Here is a sample log file in new-style XML format (`audit_log_format=NEW`), reformatted slightly for readability:

```
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD>
    <TIMESTAMP>2017-10-16T14:06:33 UTC</TIMESTAMP>
    <RECORD_ID>1_2017-10-16T14:06:33</RECORD_ID>
    <NAME>Audit</NAME>
    <SERVER_ID>1</SERVER_ID>
    <VERSION>1</VERSION>
    <STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
      --socket=/usr/local/mysql/mysql.sock
      --port=3306</STARTUP_OPTIONS>
    <OS_VERSION>i686-Linux</OS_VERSION>
    <MYSQL_VERSION>5.5.59-log</MYSQL_VERSION>
  </AUDIT_RECORD>
  <AUDIT_RECORD>
    <TIMESTAMP>2017-10-16T14:09:38 UTC</TIMESTAMP>
    <RECORD_ID>2_2017-10-16T14:06:33</RECORD_ID>
    <NAME>Connect</NAME>
    <CONNECTION_ID>5</CONNECTION_ID>
    <STATUS>0</STATUS>
    <STATUS_CODE>0</STATUS_CODE>
    <USER>root</USER>
    <OS_LOGIN/>
    <HOST>localhost</HOST>
    <IP>127.0.0.1</IP>
    <COMMAND_CLASS>connect</COMMAND_CLASS>
    <PRIV_USER>root</PRIV_USER>
    <PROXY_USER/>
    <DB>test</DB>
  </AUDIT_RECORD>
  ...
  <AUDIT_RECORD>
    <TIMESTAMP>2017-10-16T14:09:38 UTC</TIMESTAMP>
    <RECORD_ID>6_2017-10-16T14:06:33</RECORD_ID>
    <NAME>Query</NAME>
    <CONNECTION_ID>5</CONNECTION_ID>
    <STATUS>0</STATUS>
    <STATUS_CODE>0</STATUS_CODE>
    <USER>root[root] @ localhost [127.0.0.1]</USER>
    <OS_LOGIN/>
    <HOST>localhost</HOST>
    <IP>127.0.0.1</IP>
    <COMMAND_CLASS>drop_table</COMMAND_CLASS>
    <SQLTEXT>DROP TABLE IF EXISTS t</SQLTEXT>
  </AUDIT_RECORD>
  ...
  <AUDIT_RECORD>
    <TIMESTAMP>2017-10-16T14:09:39 UTC</TIMESTAMP>
    <RECORD_ID>8_2017-10-16T14:06:33</RECORD_ID>
    <NAME>Quit</NAME>
    <CONNECTION_ID>5</CONNECTION_ID>
    <STATUS>0</STATUS>
    <STATUS_CODE>0</STATUS_CODE>
    <USER>root</USER>
    <OS_LOGIN/>
    <HOST>localhost</HOST>
    <IP>127.0.0.1</IP>
    <COMMAND_CLASS>connect</COMMAND_CLASS>
  </AUDIT_RECORD>
  ...
```

```

<AUDIT_RECORD>
  <TIMESTAMP>2017-10-16T14:09:43 UTC</TIMESTAMP>
  <RECORD_ID>11_2017-10-16T14:06:33</RECORD_ID>
  <NAME>Quit</NAME>
  <CONNECTION_ID>6</CONNECTION_ID>
  <STATUS>0</STATUS>
  <STATUS_CODE>0</STATUS_CODE>
  <USER>root</USER>
  <OS_LOGIN/>
  <HOST>localhost</HOST>
  <IP>127.0.0.1</IP>
  <COMMAND_CLASS>connect</COMMAND_CLASS>
</AUDIT_RECORD>
<AUDIT_RECORD>
  <TIMESTAMP>2017-10-16T14:09:45 UTC</TIMESTAMP>
  <RECORD_ID>12_2017-10-16T14:06:33</RECORD_ID>
  <NAME>NoAudit</NAME>
  <SERVER_ID>1</SERVER_ID>
</AUDIT_RECORD>
</AUDIT>

```

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Elements within `<AUDIT_RECORD>` elements have these characteristics:

- Some elements appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of elements within an `<AUDIT_RECORD>` element is not guaranteed.
- Element values are not fixed length. Long values may be truncated as indicated in the element descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `<`, `>`, `"`, and `&`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFF] | [#x10000-#x10FFFF]
```

The following elements are mandatory in every `<AUDIT_RECORD>` element:

- `<NAME>`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
<NAME>Query</NAME>
```

Some common `<NAME>` values:

| | |
|----------|--|
| Audit | When auditing starts, which may be server startup time |
| Connect | When a client connects, also known as logging in |
| Query | An SQL statement (executed directly) |
| Prepare | Preparation of an SQL statement; usually followed by Execute |
| Execute | Execution of an SQL statement; usually follows Prepare |
| Shutdown | Server shutdown |
| Quit | When a client disconnects |
| NoAudit | Auditing has been turned off |

The possible values are `Audit`, `Binlog Dump`, `Change user`, `Close stmt`, `Connect Out`, `Connect`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `NoAudit`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `Time`.

With the exception of `Audit` and `NoAudit`, these values correspond to the `COM_xxx` command values listed in the `mysql_com.h` header file. For example, `Create DB` and `Change user` correspond to `COM_CREATE_DB` and `COM_CHANGE_USER`, respectively.

- `<RECORD_ID>`

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.

Example:

```
<RECORD_ID>12_2017-10-16T14:06:33</RECORD_ID>
```

- `<TIMESTAMP>`

A string representing a UTC value in `YYYY-MM-DDThh:mm:ss UTC` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `<TIMESTAMP>` value occurring after the statement finishes, not when it was received.

Example:

```
<TIMESTAMP>2017-10-16T14:09:45 UTC</TIMESTAMP>
```

The following elements are optional in `<AUDIT_RECORD>` elements. Many of them occur only with specific `<NAME>` element values.

- `<COMMAND_CLASS>`

A string that indicates the type of action performed.

Example:

```
<COMMAND_CLASS>drop_table</COMMAND_CLASS>
```

The values correspond to the `Com_xxx` status variables that indicate command counts; for example `Com_drop_table` and `Com_select` count `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT LOWER(REPLACE(VARIABLE_NAME, 'COM_', '')) AS name
FROM INFORMATION_SCHEMA.GLOBAL_STATUS
WHERE VARIABLE_NAME LIKE 'COM%'
ORDER BY name;
```

- `<CONNECTION_ID>`

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example:

```
<CONNECTION_ID>127</CONNECTION_ID>
```

- `<DB>`

A string representing the default database name.

Example:

```
<DB>test</DB>
```

- [<HOST>](#)

A string representing the client host name.

Example:

```
<HOST>localhost</HOST>
```

- [<IP>](#)

A string representing the client IP address.

Example:

```
<IP>127.0.0.1</IP>
```

- [<MYSQL_VERSION>](#)

A string representing the MySQL server version. This is the same as the value of the [VERSION\(\)](#) function or [version](#) system variable.

Example:

```
<MYSQL_VERSION>5.5.59-log</MYSQL_VERSION>
```

- [<OS_LOGIN>](#)

A string representing the external user (empty if none). The value may differ from the [<USER>](#) value, for example, if the server authenticates the client using an external authentication method.

Example:

```
<OS_LOGIN>jeffrey</OS_LOGIN>
```

- [<OS_VERSION>](#)

A string representing the operating system on which the server was built or is running.

Example:

```
<OS_VERSION>x86_64-Linux</OS_VERSION>
```

- [<PRIV_USER>](#)

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the [<USER>](#) value.

Example:

```
<PRIV_USER>jeffrey</PRIV_USER>
```

- [<PROXY_USER>](#)

A string representing the proxy user (see [Section 6.2.11, "Proxy Users"](#)). The value is empty if user proxying is not in effect.

Example:

```
<PROXY_USER>developer</PROXY_USER>
```

- `<SERVER_ID>`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:

```
<SERVER_ID>1</SERVER_ID>
```

- `<SQLTEXT>`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```
<SQLTEXT>DELETE FROM t1</SQLTEXT>
```

- `<STARTUP_OPTIONS>`

A string representing the options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:

```
<STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
--port=3306 --log_output=FILE</STARTUP_OPTIONS>
```

- `<STATUS>`

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `<STATUS_CODE>` for information about how it differs from `<STATUS>`.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Section B.3.1, "Server Error Message Reference"](#).

Warnings are not logged.

Example:

```
<STATUS>1051</STATUS>
```

- `<STATUS_CODE>`

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The `STATUS_CODE` value differs from the `STATUS` value: `STATUS_CODE` is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. `STATUS` is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example:

```
<STATUS_CODE>0</STATUS_CODE>
```

- `<USER>`

A string representing the user name sent by the client. This may differ from the `<PRIV_USER>` value.

Example:

```
<USER>root[root] @ localhost [127.0.0.1]</USER>
```

- **<VERSION>**

An unsigned integer representing the version of the audit log file format.

Example:

```
<VERSION>1</VERSION>
```

Old-Style XML Audit Log File Format

Here is a sample log file in old-style XML format (`audit_log_format=OLD`), reformatted slightly for readability:

```
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:00 UTC"
    RECORD_ID="1_2017-10-16T14:25:00"
    NAME="Audit"
    SERVER_ID="1"
    VERSION="1"
    STARTUP_OPTIONS="--port=3306"
    OS_VERSION="i686-Linux"
    MYSQL_VERSION="5.5.59-log" />
  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:24 UTC"
    RECORD_ID="2_2017-10-16T14:25:00"
    NAME="Connect"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root"
    OS_LOGIN=" "
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="connect"
    PRIV_USER="root"
    PROXY_USER=" "
    DB="test" />
  ...

  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:24 UTC"
    RECORD_ID="6_2017-10-16T14:25:00"
    NAME="Query"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root[root] @ localhost [127.0.0.1]"
    OS_LOGIN=" "
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="drop_table"
    SQLTEXT="DROP TABLE IF EXISTS t" />
  ...

  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:24 UTC"
    RECORD_ID="8_2017-10-16T14:25:00"
    NAME="Quit"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root"
    OS_LOGIN=" "
    HOST="localhost"
```

```

IP="127.0.0.1"
COMMAND_CLASS="connect"
<AUDIT_RECORD
  TIMESTAMP="2017-10-16T14:25:32 UTC"
  RECORD_ID="12_2017-10-16T14:25:00"
  NAME="NoAudit"
  SERVER_ID="1" />
</AUDIT>

```

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Attributes of `<AUDIT_RECORD>` elements have these characteristics:

- Some attributes appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of attributes within an `<AUDIT_RECORD>` element is not guaranteed.
- Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `<`, `>`, `"`, and `&`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFF] | [#x10000-#x10FFFF]
```

The following attributes are mandatory in every `<AUDIT_RECORD>` element:

- **NAME**

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example: `NAME="Query"`

Some common **NAME** values:

| | |
|----------|--|
| Audit | When auditing starts, which may be server startup time |
| Connect | When a client connects, also known as logging in |
| Query | An SQL statement (executed directly) |
| Prepare | Preparation of an SQL statement; usually followed by Execute |
| Execute | Execution of an SQL statement; usually follows Prepare |
| Shutdown | Server shutdown |
| Quit | When a client disconnects |
| NoAudit | Auditing has been turned off |

The possible values are `Audit`, `Binlog Dump`, `Change user`, `Close stmt`, `Connect Out`, `Connect`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `NoAudit`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `Time`.

With the exception of `"Audit"` and `"NoAudit"`, these values correspond to the `COM_xxx` command values listed in the `mysql_com.h` header file. For example, `"Create DB"` and `"Change user"` correspond to `COM_CREATE_DB` and `COM_CHANGE_USER`, respectively.

- **RECORD_ID**

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.

Example: `RECORD_ID="12_2017-10-16T14:25:00"`

- `TIMESTAMP`

A string representing a UTC value in `YYYY-MM-DDThh:mm:ss UTC` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `TIMESTAMP` value occurring after the statement finishes, not when it was received.

Example: `TIMESTAMP="2017-10-16T14:25:32 UTC"`

The following attributes are optional in `<AUDIT_RECORD>` elements. Many of them occur only for elements with specific values of the `NAME` attribute.

- `COMMAND_CLASS`

A string that indicates the type of action performed.

Example: `COMMAND_CLASS="drop_table"`

The values correspond to the `Com_xxx` status variables that indicate command counts; for example `Com_drop_table` and `Com_select` count `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT LOWER(REPLACE(VARIABLE_NAME, 'COM_', '')) AS name
FROM INFORMATION_SCHEMA.GLOBAL_STATUS
WHERE VARIABLE_NAME LIKE 'COM%'
ORDER BY name;
```

- `CONNECTION_ID`

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example: `CONNECTION_ID="127"`

- `DB`

A string representing the default database name.

Example: `DB="test"`

- `HOST`

A string representing the client host name.

Example: `HOST="localhost"`

- `IP`

A string representing the client IP address.

Example: `IP="127.0.0.1"`

- `MYSQL_VERSION`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

Example: `MYSQL_VERSION="5.5.31-log"`

- `OS_LOGIN`

A string representing the external user (empty if none). The value may differ from `USER`, for example, if the server authenticates the client using an external authentication method.

Example: `OS_LOGIN="jeffrey"`

- `OS_VERSION`

A string representing the operating system on which the server was built or is running.

Example: `OS_VERSION="x86_64-Linux"`

- `PRIV_USER`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and it may differ from the `USER` value.

Example: `PRIV_USER="jeffrey"`

- `PROXY_USER`

A string representing the proxy user (see [Section 6.2.11, "Proxy Users"](#)). The value is empty if user proxying is not in effect.

Example: `PROXY_USER="developer"`

- `SERVER_ID`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example: `SERVER_ID="1"`

- `SQLTEXT`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example: `SQLTEXT="DELETE FROM t1"`

- `STARTUP_OPTIONS`

A string representing the options that were given on the command line or in option files when the MySQL server was started.

Example: `STARTUP_OPTIONS="--port=3306 --log_output=FILE"`

- `STATUS`

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `STATUS_CODE` for information about how it differs from `STATUS`.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Section B.3.1, “Server Error Message Reference”](#).

Warnings are not logged.

Example: `STATUS="1051"`

- `STATUS_CODE`

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The `STATUS_CODE` value differs from the `STATUS` value: `STATUS_CODE` is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. `STATUS` is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example: `STATUS_CODE="0"`

- `USER`

A string representing the user name sent by the client. This may differ from the `PRIV_USER` value.

- `VERSION`

An unsigned integer representing the version of the audit log file format.

Example: `VERSION="1"`

6.4.2.4 Audit Log Logging Control

This section describes how to control general characteristics of audit logging, such as the file to which the audit log plugin writes events and the format of written events.

- [Audit Log File Name](#)
- [Audit Log File Format](#)
- [Audit Logging Write Strategy](#)
- [Audit Log File Space Management and Name Rotation](#)

For additional information about the system variables that affect audit logging, see [Section 6.4.2.7, “Audit Log Options and System Variables”](#).

Audit Log File Name

To control the audit log file name, set the `audit_log_file` system variable at server startup. By default, the name is `audit.log` in the server data directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

When the audit plugin initializes, it checks whether a file with the audit log file name already exists. If so, the plugin checks whether the file ends with an `</AUDIT>` tag and truncates the tag before writing any `<AUDIT_RECORD>` elements. If the log file exists but does not end with `</AUDIT>` or the `</AUDIT>` tag cannot be truncated, the plugin considers the file malformed and fails to initialize. This

can occur if the server exits unexpectedly with the audit log plugin running. No logging occurs until the problem is rectified. Check the error log for diagnostic information:

```
[ERROR] Plugin 'audit_log' init function returned error.
```

To deal with this problem, either remove or rename the malformed log file and restart the server.

Audit Log File Format

To control the audit log file format, set the `audit_log_format` system variable at server startup. By default, the format is `OLD` (old-style XML format). For information about available formats, see [Section 6.4.2.3, “Audit Log File Formats”](#).

Note

Changing the value of `audit_log_format` can result in writing log entries in one format to an existing log file that contains entries in a different format. To avoid this issue, use the following procedure:

1. Stop the server.
2. Either change the value of the `audit_log_file` system variable so the plugin writes to a different file, or rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin creates a new log file and writes entries to it in the selected format.

Audit Logging Write Strategy

The audit log plugin can use any of several strategies for log writes. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

To specify a write strategy, set the `audit_log_strategy` system variable at server startup. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (`PERFORMANCE`) or to log synchronously, either using file system caching (`SEMISYNCHRONOUS`) or forcing output with a `sync()` call after each write request (`SYNCHRONOUS`).

For asynchronous write strategy, the `audit_log_buffer_size` system variable is the buffer size in bytes. Set this variable at server startup to change the buffer size. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin does not allocate this buffer for nonasynchronous write strategies.

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.
- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.
- Output goes to the buffer. A separate thread handles writes from the buffer to the log file.

With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host exits unexpectedly). To reduce this risk, set `audit_log_strategy` to use synchronous logging.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, the audit log may have events missing.

Audit Log File Space Management and Name Rotation

The audit log file has the potential to grow very large and consume a lot of disk space. To enable management of the space used by its log files, the audit log plugin provides the

`audit_log_rotate_on_size` and `audit_log_flush` system variables, which control audit log file rotation and flushing. Rotation can be done manually, or automatically based on file size.

Manual audit log file rotation. By default, `audit_log_rotate_on_size=0` and there is no log rotation except that which you perform manually. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value changes from disabled to enabled. Log file renaming must be done externally to the server. Suppose that the log file name is `audit.log` and you want to maintain the three most recent log files, cycling through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

```
mv audit.log.2 audit.log.3
mv audit.log.1 audit.log.2
mv audit.log audit.log.1
```

At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`.

2. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

```
SET GLOBAL audit_log_flush = ON;
```

Automatic size-based audit log file rotation. If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. Instead, whenever a write to the log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin closes the file, renames it, and opens a new log file.

The renamed file has a timestamp and `.xml` added to the end. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.log.15081807937726520.xml`. The last 7 digits are a fractional second part. The first 10 digits are a Unix timestamp value that can be interpreted using the `FROM_UNIXTIME()` function:

```
mysql> SELECT FROM_UNIXTIME(1508180793);
+-----+
| FROM_UNIXTIME(1508180793) |
+-----+
| 2017-10-16 14:06:33      |
+-----+
```

Note

With size-based log file rotation, renamed log files do not rotate off the end of the name sequence. Instead, they have unique names and accumulate indefinitely. To avoid excessive space use, remove old files periodically, backing them up first as necessary.

6.4.2.5 Audit Log Filtering

The `audit_log_policy` system variable controls what kinds of information the plugin writes. By default, this variable is set to `ALL` (write all auditable events), but also permits values of `LOGINS` or `QUERIES` to log only login or query events, or `NONE` to disable logging.

6.4.2.6 Audit Log Option and Variable Reference

Table 6.15 Audit Log Option and Variable Reference

| Name | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dy |
|------------------------------------|----------|-------------|------------|------------|-----------|----|
| <code>audit-log</code> | Yes | Yes | | | | |
| <code>audit_log_buffer_size</code> | Yes | Yes | Yes | | Global | No |
| <code>audit_log_file</code> | Yes | Yes | Yes | | Global | No |

| Name | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynam |
|--|----------|-------------|------------|------------|-----------|-------|
| audit_log_flush | | | Yes | | Global | Yes |
| audit_log_format | Yes | Yes | Yes | | Global | No |
| audit_log_policy | Yes | Yes | Yes | | Global | Yes |
| audit_log_rotate_on_size | Yes | Yes | Yes | | Global | Yes |
| audit_log_strategy | Yes | Yes | Yes | | Global | No |

6.4.2.7 Audit Log Options and System Variables

This section describes the command options and system variables that control operation of MySQL Enterprise Audit. If values specified at startup time are incorrect, the audit log plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it will not recognize them.

To control activation of the `audit_log` plugin, use this option:

- `--audit-log[=value]`

| Property | Value |
|----------------------------|--|
| Command-Line Format | <code>--audit-log[=value]</code> |
| Introduced | 5.5.28 |
| Type | Enumeration |
| Default Value | ON |
| Valid Values | ON OFF FORCE FORCE_PLUS_PERMANENT |

This option controls how the server loads the `audit_log` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load`. See [Section 6.4.2.1, “Installing MySQL Enterprise Audit”](#).

The option value should be one of those available for plugin-loading options, as described in [Section 5.5.1, “Installing and Uninstalling Plugins”](#). For example, `--audit-log=FORCE_PLUS_PERMANENT` tells the server to load the plugin at startup and prevents it from being removed while the server is running.

This option was added in MySQL 5.5.28.

If the audit log plugin is enabled, it exposes several system variables that permit control over logging:

```
mysql> SHOW VARIABLES LIKE 'audit_log%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| audit_log_buffer_size | 1048576 |
| audit_log_file | audit.log |
| audit_log_flush | OFF |
| audit_log_policy | ALL |
| audit_log_rotate_on_size | 0 |
| audit_log_strategy | ASYNCHRONOUS |
+-----+-----+
```

You can set any of these variables at server startup, and some of them at runtime.

- `audit_log_buffer_size`

| Property | Value |
|---|--|
| Command-Line Format | <code>--audit-log-buffer-size=#</code> |
| Introduced | 5.5.28 |
| System Variable | <code>audit_log_buffer_size</code> |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 1048576 |
| Minimum Value | 4096 |
| Maximum Value (64-bit platforms) | 18446744073709547520 |
| Maximum Value (32-bit platforms) | 4294967295 |

When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

This variable was added in MySQL 5.5.28.

- `audit_log_file`

| Property | Value |
|----------------------------|---|
| Command-Line Format | <code>--audit-log-file=file_name</code> |
| Introduced | 5.5.28 |
| System Variable | <code>audit_log_file</code> |
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | <code>audit.log</code> |

The name of the file to which the audit log plugin writes events. The default value is `audit.log`. If the file name is a relative path, the server interprets it relative to the data directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

This variable was added in MySQL 5.5.28.

- `audit_log_flush`

| Property | Value |
|------------------------|------------------------------|
| Introduced | 5.5.28 |
| System Variable | <code>audit_log_flush</code> |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | <code>OFF</code> |

When this variable is set to enabled (1 or `ON`), the audit log plugin closes and reopens its log file to flush it. (The value remains `OFF` so that you need not disable it explicitly before enabling it again to perform another flush.) Enabling this variable has no effect unless `audit_log_rotate_on_size` is 0.

This variable was added in MySQL 5.5.28.

- `audit_log_format`

| Property | Value |
|----------------------------|--|
| Command-Line Format | <code>--audit-log-format=value</code> |
| Introduced | 5.5.34 |
| System Variable | <code>audit_log_format</code> |
| Scope | Global |
| Dynamic | No |
| Type | Enumeration |
| Default Value | <code>OLD</code> |
| Valid Values | <code>OLD</code> <code>NEW</code> |

The audit log file format. Permitted values are `OLD` and `NEW` (default `OLD`). For details about each format, see [Section 6.4.2.3, “Audit Log File Formats”](#).

Changing the value of `audit_log_format` can result in writing log entries in one format to an existing log file that contains entries in a different format. To avoid this issue, use the procedure described at [Audit Log File Format](#).

This variable was added in MySQL 5.5.34.

- `audit_log_policy`

| Property | Value |
|----------------------------|---|
| Command-Line Format | <code>--audit-log-policy=value</code> |
| Introduced | 5.5.28 |
| System Variable | <code>audit_log_policy</code> |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | <code>ALL</code> |
| Valid Values | <code>ALL</code> <code>LOGINS</code> <code>QUERIES</code> |

| Property | Value |
|----------|-------|
| | NONE |

The policy controlling the information written by the audit log plugin to its log file. The following table shows the permitted values.

| Value | Description |
|---------|--|
| ALL | Log all events |
| NONE | Log nothing (disable the audit stream) |
| LOGINS | Log only login events |
| QUERIES | Log only query events |

This variable was added in MySQL 5.5.28.

- [audit_log_rotate_on_size](#)

| Property | Value |
|----------------------------|---|
| Command-Line Format | <code>--audit-log-rotate-on-size=#</code> |
| Introduced | 5.5.28 |
| System Variable | audit_log_rotate_on_size |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |

If the [audit_log_rotate_on_size](#) value is 0, the audit log plugin does not perform automatic log file rotation. Instead, use [audit_log_flush](#) to close and reopen the log on demand. In this case, manually rename the file externally to the server before flushing it.

If the [audit_log_rotate_on_size](#) value is greater than 0, automatic size-based log file rotation occurs. Whenever a write to the log file causes its size to exceed the [audit_log_rotate_on_size](#) value, the audit log plugin closes the current log file, renames it, and opens a new log file.

For more information about audit log file rotation, see [Audit Log File Space Management and Name Rotation](#).

If you set this variable to a value that is not a multiple of 4096, it is truncated to the nearest multiple. (Thus, setting it to a value less than 4096 has the effect of setting it to 0 and no rotation occurs, except manually.)

This variable was added in MySQL 5.5.28.

- [audit_log_strategy](#)

| Property | Value |
|----------------------------|---|
| Command-Line Format | <code>--audit-log-strategy=value</code> |
| Introduced | 5.5.28 |
| System Variable | audit_log_strategy |
| Scope | Global |
| Dynamic | No |

| Property | Value |
|---------------|--|
| Type | Enumeration |
| Default Value | ASYNCHRONOUS |
| Valid Values | ASYNCHRONOUS PERFORMANCE SEMI SYNCHRONOUS SYNCHRONOUS |

The logging method used by the audit log plugin. These strategy values are permitted:

- **ASYNCHRONOUS**: Log asynchronously. Wait for space in the output buffer.
- **PERFORMANCE**: Log asynchronously. Drop requests for which there is insufficient space in the output buffer.
- **SEMI SYNCHRONOUS**: Log synchronously. Permit caching by the operating system.
- **SYNCHRONOUS**: Log synchronously. Call `sync()` after each request.

This variable was added in MySQL 5.5.28.

6.4.2.8 Audit Log Restrictions

MySQL Enterprise Audit is subject to these general restrictions:

- Only SQL statements are logged. Changes made by no-SQL APIs, such as memcached, Node.JS, and the NDB API, are not logged.
- Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.
- Contents of files referenced by statements such as `LOAD DATA` are not logged.

NDB Cluster. It is possible to use MySQL Enterprise Audit with MySQL NDB Cluster, subject to the following conditions:

- All changes to be logged must be done using the SQL interface. Changes using no-SQL interfaces, such as those provided by the NDB API, memcached, or ClusterJ, are not logged.
- The plugin must be installed on each MySQL server that is used to execute SQL on the cluster.
- Audit plugin data must be aggregated amongst all MySQL servers used with the cluster. This aggregation is the responsibility of the application or user.

Chapter 7 Backup and Recovery

Table of Contents

| | |
|---|-----|
| 7.1 Backup and Recovery Types | 804 |
| 7.2 Database Backup Methods | 807 |
| 7.3 Example Backup and Recovery Strategy | 809 |
| 7.3.1 Establishing a Backup Policy | 809 |
| 7.3.2 Using Backups for Recovery | 811 |
| 7.3.3 Backup Strategy Summary | 812 |
| 7.4 Using mysqldump for Backups | 812 |
| 7.4.1 Dumping Data in SQL Format with mysqldump | 812 |
| 7.4.2 Reloading SQL-Format Backups | 813 |
| 7.4.3 Dumping Data in Delimited-Text Format with mysqldump | 814 |
| 7.4.4 Reloading Delimited-Text Format Backups | 815 |
| 7.4.5 mysqldump Tips | 815 |
| 7.5 Point-in-Time (Incremental) Recovery Using the Binary Log | 817 |
| 7.5.1 Point-in-Time Recovery Using Event Times | 819 |
| 7.5.2 Point-in-Time Recovery Using Event Positions | 819 |
| 7.6 MyISAM Table Maintenance and Crash Recovery | 820 |
| 7.6.1 Using myisamchk for Crash Recovery | 820 |
| 7.6.2 How to Check MyISAM Tables for Errors | 821 |
| 7.6.3 How to Repair MyISAM Tables | 822 |
| 7.6.4 MyISAM Table Optimization | 824 |
| 7.6.5 Setting Up a MyISAM Table Maintenance Schedule | 824 |

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replication slave servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

- Types of backups: Logical versus physical, full versus incremental, and so forth.
- Methods for creating backups.
- Recovery methods, including point-in-time recovery.
- Backup scheduling, compression, and encryption.
- Table maintenance, to enable recovery of corrupt tables.

Additional Resources

Resources related to backup or to maintaining data availability include the following:

- Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product for backups. For an overview of the MySQL Enterprise Backup product, see [Section 25.2, “MySQL Enterprise Backup Overview”](#).
- A forum dedicated to backup issues is available at <https://forums.mysql.com/list.php?28>.
- Details for [mysqldump](#), [mysqlhotcopy](#), and other MySQL backup programs can be found in [Chapter 4, MySQL Programs](#).
- The syntax of the SQL statements described here is given in [Chapter 13, SQL Statements](#).

- For additional information about [InnoDB](#) backup procedures, see [Section 14.21.1, “InnoDB Backup”](#).
- Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the master by using a slave server. See [Chapter 17, Replication](#).
- NDB Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See [Chapter 18, MySQL NDB Cluster 7.2](#). For information specifically about NDB Cluster backup, see [Section 18.5.3, “Online Backup of NDB Cluster”](#).
- Distributed Replicated Block Device (DRBD) is another high-availability solution. It works by replicating a block device from a primary server to a secondary server at the block level. See [Chapter 16, High Availability and Scalability](#)

7.1 Backup and Recovery Types

This section describes the characteristics of different types of backups.

Physical (Raw) Versus Logical Backups

Physical backups consist of raw copies of the directories and files that store database contents. This type of backup is suitable for large, important databases that need to be recovered quickly when problems occur.

Logical backups save information represented as logical database structure ([CREATE DATABASE](#), [CREATE TABLE](#) statements) and content ([INSERT](#) statements or delimited-text files). This type of backup is suitable for smaller amounts of data where you might edit the data values or table structure, or recreate the data on a different machine architecture.

Physical backup methods have these characteristics:

- The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory.
- Physical backup methods are faster than logical because they involve only file copying without conversion.
- Output is more compact than for logical backup.
- Because backup speed and compactness are important for busy, important databases, the MySQL Enterprise Backup product performs physical backups. For an overview of the MySQL Enterprise Backup product, see [Section 25.2, “MySQL Enterprise Backup Overview”](#).
- Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. For example, [InnoDB](#) tables can each be in a separate file, or share file storage with other [InnoDB](#) tables; each [MyISAM](#) table corresponds uniquely to a set of files.
- In addition to databases, the backup can include any related files such as log or configuration files.
- Data from [MEMORY](#) tables is tricky to back up this way because their contents are not stored on disk. (The MySQL Enterprise Backup product has a feature where you can retrieve data from [MEMORY](#) tables during a backup.)
- Backups are portable only to other machines that have identical or similar hardware characteristics.
- Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup. MySQL Enterprise Backup does this locking automatically for tables that require it.

- Physical backup tools include the `mysqlbackup` of MySQL Enterprise Backup for `InnoDB` or any other tables, file system-level commands (such as `cp`, `scp`, `tar`, `rsync`), or `mysqlhotcopy` for `MyISAM` tables.
- For restore:
 - MySQL Enterprise Backup restores `InnoDB` and other tables that it backed up.
 - `ndb_restore` restores `NDB` tables.
 - Files copied at the file system level or with `mysqlhotcopy` can be copied back to their original locations with file system commands.

Logical backup methods have these characteristics:

- The backup is done by querying the MySQL server to obtain database structure and content information.
- Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.
- Output is larger than for physical backup, particularly when saved in text format.
- Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.
- The backup does not include log or configuration files, or other database-related files that are not part of databases.
- Backups stored in logical format are machine independent and highly portable.
- Logical backups are performed with the MySQL server running. The server is not taken offline.
- Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even `MEMORY`.
- To restore logical backups, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA` statement or the `mysqlimport` client.

Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

- The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.
- Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity. The MySQL Enterprise Backup product does such locking automatically.

Offline backup methods have these characteristics:

- Clients can be affected adversely because the server is unavailable during backup. For that reason, such backups are often taken from a replication slave server that can be taken offline without harming availability.
- The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely that clients will be affected for online recovery than for online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

Local Versus Remote Backups

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server. host.

- `mysqldump` can connect to local or remote servers. For SQL output (`CREATE` and `INSERT` statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` option), data files are created on the server host.
- `mysqlhotcopy` performs only local backups: It connects to the server to lock it against data modifications and then copies local table files.
- `SELECT ... INTO OUTFILE` can be initiated from a local or remote client host, but the output file is created on the server host.
- Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

Full Versus Point-in-Time (Incremental) Recovery

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server's state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

Table Maintenance

Data integrity can be compromised if tables become corrupt. For `InnoDB` tables, this is not a typical issue. For programs to check `MyISAM` tables and repair them if problems are found, see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. The MySQL Enterprise Backup product can compress [InnoDB](#) backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

7.2 Database Backup Methods

This section summarizes some general methods for making backups.

Making a Hot Backup with MySQL Enterprise Backup

Customers of MySQL Enterprise Edition can use the [MySQL Enterprise Backup](#) product to do [physical](#) backups of entire instances or selected databases, tables, or both. This product includes features for [incremental](#) and [compressed](#) backups. Backing up the physical database files makes restore much faster than logical techniques such as the `mysqldump` command. [InnoDB](#) tables are copied using a [hot backup](#) mechanism. (Ideally, the [InnoDB](#) tables should represent a substantial majority of the data.) Tables from other storage engines are copied using a [warm backup](#) mechanism. For an overview of the MySQL Enterprise Backup product, see [Section 25.2, “MySQL Enterprise Backup Overview”](#).

Making Backups with `mysqldump` or `mysqlhotcopy`

The `mysqldump` program and the `mysqlhotcopy` script can make backups. `mysqldump` is more general because it can back up all kinds of tables. `mysqlhotcopy` works only with some storage engines. (See [Section 7.4, “Using `mysqldump` for Backups”](#), and [Section 4.6.9, “`mysqlhotcopy` — A Database Backup Program”](#).)

For [InnoDB](#) tables, it is possible to perform an online backup that takes no locks on tables using the `--single-transaction` option to `mysqldump`. See [Section 7.3.1, “Establishing a Backup Policy”](#).

Making Backups by Copying Table Files

For storage engines that represent each table using its own files, tables can be backed up by copying those files. For example, [MyISAM](#) tables are stored as files, so it is easy to do a backup by copying files (`*.frm`, `*.MYD`, and `*.MYI` files). To get a consistent backup, stop the server or lock and flush the relevant tables:

```
FLUSH TABLES tbl_list WITH READ LOCK;
```

You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The flush is needed to ensure that all active index pages are written to disk before you start the backup. See [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Statements”](#), and [Section 13.7.6.3, “FLUSH Statement”](#).

You can also create a binary backup simply by copying all table files, as long as the server isn't updating anything. The `mysqlhotcopy` script uses this method. (But note that table file copying methods do not work if your database contains [InnoDB](#) tables. `mysqlhotcopy` does not work for [InnoDB](#) tables because [InnoDB](#) does not necessarily store table contents in database directories. Also, even if the server is not actively updating data, [InnoDB](#) may still have modified data cached in memory and not flushed to disk.)

Making Delimited-Text File Backups

To create a text file containing a table's data, you can use `SELECT * INTO OUTFILE 'file_name' FROM tbl_name`. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk.

See [Section 13.2.9, “SELECT Statement”](#). This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing `CREATE TABLE` statements for the backed up tables) is to use `mysqldump` with the `--tab` option. See [Section 7.4.3, “Dumping Data in Delimited-Text Format with `mysqldump`”](#).

To reload a delimited-text data file, use `LOAD DATA` or `mysqlimport`.

Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups: You must start the server with the `--log-bin` option to enable binary logging; see [Section 5.4.4, “The Binary Log”](#). The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#). The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS`, `mysqldump --flush-logs`, or `mysqlhotcopy --flushlog`. See [Section 4.5.4, “`mysqldump` — A Database Backup Program”](#), and [Section 4.6.9, “`mysqlhotcopy` — A Database Backup Program”](#).

Making Backups Using Replication Slaves

If you have performance problems with your master server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See [Section 17.3.1, “Using Replication for Backups”](#).

If you are backing up a slave replication server, you should back up its `master.info` and `relay-log.info` files when you back up the slave's databases, regardless of the backup method you choose. These information files are always needed to resume replication after you restore the slave's data. If your slave is replicating `LOAD DATA` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA` operations. The location of this directory is the value of the `slave_load_tmpdir` system variable. If the server was not started with that variable set, the directory location is the value of the `tmpdir` system variable.

Recovering Corrupt Tables

If you have to restore `MyISAM` tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

7.3 Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the `InnoDB` storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The `InnoDB` data files might not contain consistent data due to the crash, but `InnoDB` reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. `InnoDB` automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

7.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, [MySQL Enterprise Backup](#) can perform a [physical backup](#) of an entire instance, with optimizations to minimize overhead and avoid disruption

when backing up InnoDB data files; `mysqldump` provides online [logical backup](#). This discussion uses `mysqldump`.

Assume that we make a full backup of all our InnoDB tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
shell> mysqldump --all-databases --master-data --single-transaction > backup_sunday_1_PM.sql
```

The resulting `.sql` file produced by `mysqldump` contains a set of SQL `INSERT` statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using `FLUSH TABLES WITH READ LOCK`). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are InnoDB tables, so `--single-transaction` uses a consistent read and guarantees that data seen by `mysqldump` does not change. (Changes made by other clients to InnoDB tables are not seen by the `mysqldump` process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the MyISAM tables in the `mysql` database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the `--log-bin` option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that was started with the `--log-bin` option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem guilhem 1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem guilhem      4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem guilhem    79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem guilhem   508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem guilhem  998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem guilhem   361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`, because the `--flush-logs` option causes the server to flush its logs. The `--master-`

`data` option causes `mysqldump` to write binary log information to its output, so the resulting `.sql` dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or higher.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file or higher.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

Note

Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See [Section 13.4.1.1, “PURGE BINARY LOGS Statement”](#).

7.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any

subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

7.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=log_name`, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in [Section 7.3.1, “Establishing a Backup Policy”](#), that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

7.4 Using `mysqldump` for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replication slaves.
- As a source of data for experimentation:
 - To make a copy of a database that you can use without changing the original data.
 - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

- Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.
- With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

7.4.1 Dumping Data in SQL Format with `mysqldump`

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see [Section 7.4.2, “Reloading SQL-Format Backups”](#).

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```
shell> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` option:

```
shell> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` option:

```
shell> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.

With `--all-databases` or `--databases`, `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
shell> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` option:

```
shell> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases`, the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output will contain no `CREATE DATABASE` statement, the `--add-drop-database` option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
shell> mysqldump test t1 t3 t7 > dump.sql
```

7.4.2 Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` or `--databases` option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
shell> mysql < dump.sql
```

Alternatively, from within `mysql`, use a `source` command:

```
mysql> source dump.sql
```

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```
shell> mysqladmin create db1
```

Then specify the database name when you load the dump file:

```
shell> mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

Note

For Windows PowerShell users: Because the "<" character is reserved for future use in PowerShell, an alternative approach is required, such as using quotes `cmd.exe /c "mysql < dump.sql"`.

7.4.3 Dumping Data in Delimited-Text Format with mysqldump

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see [Section 7.4.4, "Reloading Delimited-Text Format Backups"](#).

If you invoke `mysqldump` with the `--tab=dir_name` option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the base name for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```
shell> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` be used only for dumping a local server. If you use it with a remote server, the `--tab` directory must exist on both the local and remote hosts, and the `.txt` files will be written by the server in the remote directory (on the server host), whereas the `.sql` files will be written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=str`

The string for separating column values (default: tab).

- `--fields-enclosed-by=char`

The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=char`

The character within which to enclose non-numeric column values (default: no character).

- `--fields-escaped-by=char`

The character for escaping special characters (default: no escaping).

- `--lines-terminated-by=str`

The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='\"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=,
--fields-enclosed-by='\"' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you will need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

7.4.4 Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:

```
shell> mysql db1 < t1.sql
shell> mysqlimport db1 t1.txt
```

An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA` statement from within the `mysql` client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA` to ensure proper interpretation of the data file contents:

```
shell> mysqlimport --fields-terminated-by=,
--fields-enclosed-by='\"' --lines-terminated-by=0x0d0a db1 t1.txt
```

Or:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY '\"'
LINES TERMINATED BY '\r\n';
```

7.4.5 mysqldump Tips

This section surveys techniques that enable you to use `mysqldump` to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

7.4.5.1 Making a Copy of a Database

```
shell> mysqldump db1 > dump.sql
shell> mysqladmin create db2
shell> mysql db2 < dump.sql
```

Do not use `--databases` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.

7.4.5.2 Copy a Database from one Server to Another

On Server 1:

```
shell> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
shell> mysql < dump.sql
```

Use of `--databases` with the `mysqldump` command line causes the dump file to include `CREATE DATABASE` and `USE` statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` from the `mysqldump` command. Then you will need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```
shell> mysqldump db1 > dump.sql
```

On Server 2:

```
shell> mysqladmin create db1
shell> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases` from the `mysqldump` command enables you to dump data from one database and load it into another.

7.4.5.3 Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

- `--events`: Dump Event Scheduler events
- `--routines`: Dump stored procedures and functions
- `--triggers`: Dump triggers for tables

The `--triggers` option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events`, `--skip-routines`, or `--skip-triggers`.

7.4.5.4 Dumping Table Definitions and Content Separately

The `--no-data` option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```
shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` and `--events` options to also include stored routine and event definitions:

```
shell> mysqldump --no-data --routines --events test > dump-defs.sql
```

7.4.5.5 Using `mysqldump` to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
shell> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```
shell> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

7.5 Point-in-Time (Incremental) Recovery Using the Binary Log

Point-in-time recovery refers to recovery of data changes made since a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in [Section 7.2, “Database Backup Methods”](#).) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

Note

Many of the examples here use the `mysql` client to process binary log output produced by `mysqlbinlog`. If your binary log contains `\0` (null) characters, that output cannot be parsed by `mysql` unless you invoke it with the `--binary-mode` option (available in MySQL 5.6).

Point-in-time recovery is based on these principles:

- The source of information for point-in-time recovery is the set of incremental backups represented by the binary log files generated subsequent to the full backup operation. Therefore, the server must be started with the `--log-bin` option to enable binary logging (see [Section 5.4.4, “The Binary Log”](#)).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. [Section 5.4.4, “The Binary Log”](#).

To see a listing of all binary log files, use this statement:

```
mysql> SHOW BINARY LOGS;
```

To determine the name of the current binary log file, issue the following statement:

```
mysql> SHOW MASTER STATUS;
```

- The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be executed or viewed. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).
- Executing events from the binary log causes the data modifications they represent to be redone. This enables recovery of data changes for a given span of time. To execute events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```
shell> mysqlbinlog binlog_files | mysql -u root -p
```

- Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```
shell> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```
shell> mysqlbinlog binlog_files > tmpfile
shell> ... edit tmpfile ...
```

- Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental `DROP DATABASE`. You can delete from the file any statements not to be executed before executing its contents. After editing the file, execute the contents as follows:

```
shell> mysql -u root -p < tmpfile
```

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* connection to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

7.5.1 Point-in-Time Recovery Using Event Times

To indicate the start and end times for recovery, specify the `--start-datetime` and `--stop-datetime` options for `mysqlbinlog`, in `DATETIME` format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore the table and data, you could restore the previous night's backup, and then execute the following command:

```
shell> mysqlbinlog --stop-datetime="2005-04-20 9:59:59" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

This command recovers all of the data up until the date and time given by the `--stop-datetime` option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run `mysqlbinlog` again with a start date and time, like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 10:01:00" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two `mysqlbinlog` commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on.

To use this method of point-in-time recovery, you should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```
shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

Then open the `/tmp/mysql_restore.sql` file with a text editor to examine it.

Excluding specific changes by specifying times for `mysqlbinlog` does not work well if multiple statements executed at the same time as the one to be excluded.

7.5.2 Point-in-Time Recovery Using Event Positions

Instead of specifying dates and times, the `--start-position` and `--stop-position` options for `mysqlbinlog` can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, run `mysqlbinlog` for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 9:55:00" \
--stop-datetime="2005-04-20 10:05:00" \
/var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This command creates a small text file in the `/tmp` directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you do not want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as `log_pos` followed by a number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

```
shell> mysqlbinlog --stop-position=368312 /var/log/mysql/bin.123456 \
```

```
| mysql -u root -p
shell> mysqlbinlog --start-position=368315 /var/log/mysql/bin.123456 \
| mysql -u root -p
```

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

7.6 MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). Other table-repair information can be found at [Section 2.11.7, “Rebuilding or Repairing Tables or Indexes”](#).

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause `FULLTEXT` indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in [Section 4.6.3.1, “myisamchk General Options”](#).

MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what `myisamchk` can do:

- To check MyISAM tables, use `CHECK TABLE`.
- To repair MyISAM tables, use `REPAIR TABLE`.
- To optimize MyISAM tables, use `OPTIMIZE TABLE`.
- To analyze MyISAM tables, use `ANALYZE TABLE`.

For additional information about these statements, see [Section 13.7.2, “Table Maintenance Statements”](#).

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server.

7.6.1 Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See [Section B.4.3.3, “What to Do If MySQL Keeps Crashing”](#).

For an explanation of how MyISAM tables can become corrupted, see [Section 15.3.4, “MyISAM Table Problems”](#).

If you run `mysqld` with external locking disabled (which is the default), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one will access the tables through `mysqld` while you run `myisamchk`, you only have to execute

`mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each MyISAM table `tbl_name` in a database corresponds to the three files in the database directory shown in the following table.

| File | Purpose |
|---------------------------|--------------------------|
| <code>tbl_name.frm</code> | Definition (format) file |
| <code>tbl_name.MYD</code> | Data file |
| <code>tbl_name.MYI</code> | Index file |

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

7.6.2 How to Check MyISAM Tables for Errors

To check a MyISAM table, use the following commands:

- `myisamchk tbl_name`

This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

- `myisamchk -m tbl_name`

This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e tbl_name`

This does a complete and thorough check of all data (`-e` means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i tbl_name`

This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

7.6.3 How to Repair MyISAM Tables

The discussion in this section describes how to use `myisamchk` on MyISAM tables (extensions `.MYI` and `.MYD`).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See [Section 13.7.2.2, “CHECK TABLE Statement”](#), and [Section 13.7.2.5, “REPAIR TABLE Statement”](#).

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- `tbl_name.frm` is locked against change
- Can't find file `tbl_name.MYI` (Errcode: `nnn`)
- Unexpected end of file
- Record file is crashed
- Got error `nnn` from table handler

To get more information about the error, run `pererror nnn`, where `nnn` is the error number. The following example shows how to use `pererror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> pererror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in [Section 7.6.2, “How to Check MyISAM Tables for Errors”](#)), or you want to use the extended features that `myisamchk` provides.

The `myisamchk` options used for table maintenance with are described in [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). `myisamchk` also has variables that you can set to control memory allocation that may improve performance. See [Section 4.6.3.6, “myisamchk Memory Usage”](#).

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still available for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

Stage 1: Checking your tables

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state` option to tell `myisamchk` to mark the table as “checked.”

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 2: Easy safe repair

First, try `myisamchk -r -q tbl_name` (`-r -q` means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

Note

If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
shell> mysql db_name
mysql> SET autocommit=1;
mysql> TRUNCATE TABLE tbl_name;
```

```
mysql> quit
```

- Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

Important

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See [Section 13.7.2.5, “REPAIR TABLE Statement”](#).

Stage 4: Very difficult repair

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file is not changed after the table is created:

- Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.
- If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

7.6.4 MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See [Section 13.7.2.4, “OPTIMIZE TABLE Statement”](#).

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.
- `--sort-index` or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.
- `--sort-records=index_num` or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

7.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See [Section 13.7.2, “Table Maintenance Statements”](#).

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check MyISAM tables automatically, start it with the `myisam_recover_options` system variable set. See [Section 5.1.7, “Server System Variables”](#).

You should also check your tables regularly during normal system operation. For example, you can run a `cron` job to check important tables once a week, using a line like this in a `crontab` file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with `VARCHAR`, `BLOB`, or `TEXT` columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the `mysqld` server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --myisam_sort_buffer_size=16M */*.MYI
```

This chapter explains how to optimize MySQL performance and provides examples. Optimization involves configuring, tuning, and measuring performance, at several levels. Depending on your job role (developer, DBA, or a combination of both), you might optimize at the level of individual SQL statements, entire applications, a single database server, or multiple networked database servers. Sometimes you can be proactive and plan in advance for performance, while other times you might troubleshoot a configuration or code issue after a problem occurs. Optimizing CPU and memory usage can also improve scalability, allowing the database to handle more load without slowing down.

8.1 Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, which you must minimize and make as efficient as possible. As you work on database performance, you start by learning the high-level rules and guidelines for the software side, and measuring performance using wall-clock time. As you become an expert, you learn more about what happens internally, and start measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop their own storage engines and hardware appliances to expand the MySQL ecosystem.

- [Optimizing at the Database Level](#)
- [Optimizing at the Hardware Level](#)
- [Balancing Portability and Performance](#)

Optimizing at the Database Level

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does each table have the appropriate columns for the type of work? For example, applications that perform frequent updates often have many tables with few columns, while applications that analyze large amounts of data often have few tables with many columns.
- Are the right [indexes](#) in place to make queries efficient?
- Are you using the appropriate storage engine for each table, and taking advantage of the strengths and features of each storage engine you use? In particular, the choice of a transactional storage engine such as [InnoDB](#) or a nontransactional one such as [MyISAM](#) can be very important for performance and scalability.

Note

[InnoDB](#) is the default storage engine for new tables. In practice, the advanced [InnoDB](#) performance features mean that [InnoDB](#) tables often outperform the simpler [MyISAM](#) tables, especially for a busy database.

- Does each table use an appropriate row format? This choice also depends on the storage engine used for the table. In particular, compressed tables use less disk space and so require less disk I/O to read and write the data. Compression is available for all kinds of workloads with [InnoDB](#) tables, and for read-only [MyISAM](#) tables.
- Does the application use an appropriate [locking strategy](#)? For example, by allowing shared access when possible so that database operations can run concurrently, and requesting exclusive access when appropriate so that critical operations get top priority. Again, the choice of storage engine is significant. The [InnoDB](#) storage engine handles most locking issues without involvement from you, allowing for better concurrency in the database and reducing the amount of experimentation and tuning for your code.
- Are all [memory areas used for caching](#) sized correctly? That is, large enough to hold frequently accessed data, but not so large that they overload physical memory and cause paging. The main memory areas to configure are the [InnoDB](#) buffer pool, the [MyISAM](#) key cache, and the MySQL query cache.

Optimizing at the Hardware Level

Any database application eventually hits hardware limits as the database becomes more and more busy. A DBA must evaluate whether it is possible to tune the application or reconfigure the server to avoid these [bottlenecks](#), or whether more hardware resources are required. System bottlenecks typically arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.
- Disk reading and writing. When the disk is at the correct position, we need to read or write the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.
- CPU cycles. When the data is in main memory, we must process it to get our result. Having large tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

Balancing Portability and Performance

To use performance-oriented SQL extensions in a portable MySQL program, you can wrap MySQL-specific keywords in a statement within `/* ! */` comment delimiters. Other SQL servers ignore the commented keywords. For information about writing comments, see [Section 9.6, “Comment Syntax”](#).

8.2 Optimizing SQL Statements

The core logic of a database application is performed through SQL statements, whether issued directly through an interpreter or submitted behind the scenes through an API. The tuning guidelines in this section help to speed up all kinds of MySQL applications. The guidelines cover SQL operations that read and write data, the behind-the-scenes overhead for SQL operations in general, and operations used in specific scenarios such as database monitoring.

8.2.1 Optimizing SELECT Statements

Queries, in the form of `SELECT` statements, perform all the lookup operations in the database. Tuning these statements is a top priority, whether to achieve sub-second response times for dynamic web pages, or to chop hours off the time to generate huge overnight reports.

Besides `SELECT` statements, the tuning techniques for queries also apply to constructs such as `CREATE TABLE...AS SELECT`, `INSERT INTO...SELECT`, and `WHERE` clauses in `DELETE` statements. Those statements have additional performance considerations because they combine write operations with the read-oriented query operations.

In MySQL NDB Cluster 7.2 and later, the `NDB` storage engine supports a join pushdown optimization whereby a qualifying join is sent in its entirety to NDB Cluster data nodes, where it can be distributed among them and executed in parallel. For more information about this optimization, see [Conditions for NDB pushdown joins](#).

The main considerations for optimizing queries are:

- To make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an `index`. Set up indexes on columns used in the `WHERE` clause, to speed up evaluation, filtering, and the final retrieval of results. To avoid wasted disk space, construct a small set of indexes that speed up many related queries used in your application.

Indexes are especially important for queries that reference different tables, using features such as `joins` and `foreign keys`. You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See [Section 8.3.1, “How MySQL Uses Indexes”](#) and [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#).

- Isolate and tune any part of the query, such as a function call, that takes excessive time. Depending on how the query is structured, a function could be called once for every row in the result set, or even once for every row in the table, greatly magnifying any inefficiency.
- Minimize the number of `full table scans` in your queries, particularly for big tables.
- Keep table statistics up to date by using the `ANALYZE TABLE` statement periodically, so the optimizer has the information needed to construct an efficient execution plan.
- Learn the tuning techniques, indexing techniques, and configuration parameters that are specific to the storage engine for each table. Both `InnoDB` and `MyISAM` have sets of guidelines for enabling and sustaining high performance in queries. For details, see [Section 8.5.5, “Optimizing InnoDB Queries”](#) and [Section 8.6.1, “Optimizing MyISAM Queries”](#).
- Avoid transforming the query in ways that make it hard to understand, especially if the optimizer does some of the same transformations automatically.
- If a performance issue is not easily solved by one of the basic guidelines, investigate the internal details of the specific query by reading the `EXPLAIN` plan and adjusting your indexes, `WHERE`

clauses, join clauses, and so on. (When you reach a certain level of expertise, reading the [EXPLAIN](#) plan might be your first step for every query.)

- Adjust the size and properties of the memory areas that MySQL uses for caching. With efficient use of the [InnoDB buffer pool](#), [MyISAM](#) key cache, and the MySQL query cache, repeated queries run faster because the results are retrieved from memory the second and subsequent times.
- Even for a query that runs fast using the cache memory areas, you might still optimize further so that they require less cache memory, making your application more scalable. Scalability means that your application can handle more simultaneous users, larger requests, and so on without experiencing a big drop in performance.
- Deal with locking issues, where the speed of your query might be affected by other sessions accessing the tables at the same time.

8.2.1.1 WHERE Clause Optimization

This section discusses optimizations that can be made for processing [WHERE](#) clauses. The examples use [SELECT](#) statements, but the same optimizations apply for [WHERE](#) clauses in [DELETE](#) and [UPDATE](#) statements.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;

SELECT MAX(key_part2) FROM tbl_name
WHERE key_part1=constant;

SELECT ... FROM tbl_name
ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the entries from a secondary index, if the indexed columns are numeric:

```
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
WHERE key_part1=val1 AND key_part2=val2;

SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use the index data to retrieve the rows in sorted order without a separate sorting pass:

```
SELECT ... FROM tbl_name
ORDER BY key_part1,key_part2,... ;

SELECT ... FROM tbl_name
ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

You might be tempted to rewrite your queries to make arithmetic operations faster, while sacrificing readability. Because MySQL does similar optimizations automatically, you can often avoid this work, and leave the query in a more understandable and maintainable form. Some of the optimizations performed by MySQL follow:

Note

Because work on the MySQL optimizer is ongoing, not all of the optimizations that MySQL performs are documented here.

- Removal of unnecessary parentheses:

```
((a AND b) AND c OR ((a AND b) AND (c AND d)))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
(a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

- Constant condition removal:

```
(b>=5 AND b=5) OR (b=6 AND 5=5) OR (b=7 AND 5=6)
-> b=5 OR b=6
```

- Constant expressions used by indexes are evaluated only once.
- `COUNT(*)` on a single table without a `WHERE` is retrieved directly from the table information for `MyISAM` and `MEMORY` tables. This is also done for any `NOT NULL` expression when used with only one table.
- Early detection of invalid constant expressions. MySQL quickly detects that some `SELECT` statements are impossible and returns no rows.
- `HAVING` is merged with `WHERE` if you do not use `GROUP BY` or aggregate functions (`COUNT()`, `MIN()`, and so on).
- For each table in a join, a simpler `WHERE` is constructed to get a fast `WHERE` evaluation for the table and also to skip rows as soon as possible.
- All constant tables are read first before any other tables in the query. A constant table is any of the following:
 - An empty table or a table with one row.
 - A table that is used with a `WHERE` clause on a `PRIMARY KEY` or a `UNIQUE` index, where all index parts are compared to constant expressions and are defined as `NOT NULL`.

All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in `ORDER BY` and `GROUP BY` clauses come from the same table, that table is preferred first when joining.
- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the `SQL_SMALL_RESULT` modifier, MySQL uses an in-memory temporary table.
- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.
- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.
- Before each row is output, those that do not match the `HAVING` clause are skipped.

8.2.1.2 Range Optimization

The `range` access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections give a detailed description of how intervals are extracted from the `WHERE` clause.

- [Range Access Method for Single-Part Indexes](#)
- [Range Access Method for Multiple-Part Indexes](#)

Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the `WHERE` clause, denoted as *range conditions* rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both `BTREE` and `HASH` indexes, comparison of a key part with a constant value is a range condition when using the `=`, `<=>`, `IN()`, `IS NULL`, or `IS NOT NULL` operators.
- Additionally, for `BTREE` indexes, comparison of a key part with a constant value is a range condition when using the `>`, `<`, `>=`, `<=`, `BETWEEN`, `!=`, or `<>` operators, or `LIKE` comparisons if the argument to `LIKE` is a constant string that does not start with a wildcard character.
- For all index types, multiple range conditions combined with `OR` or `AND` form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a `const` or `system` table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the `WHERE` clause:

```
SELECT * FROM t1
  WHERE key_col > 1
     AND key_col < 10;

SELECT * FROM t1
  WHERE key_col = 1
     OR key_col IN (15,18,20);

SELECT * FROM t1
  WHERE key_col LIKE 'ab%'
     OR key_col BETWEEN 'bar' AND 'foo';
```

Some nonconstant values may be converted to constants during the optimizer constant propagation phase.

MySQL tries to extract range conditions from the `WHERE` clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where `key1` is an indexed column and `nonkey` is not indexed:

```
SELECT * FROM t1 WHERE
  (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
  (key1 < 'bar' AND nonkey = 4) OR
```

```
(key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z')
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Replacing them with `TRUE` yields:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z')
```

3. Collapse conditions that are always true or false:

- `(key1 LIKE 'abcde%' OR TRUE)` is always true
- `(key1 < 'uux' AND key1 > 'z')` is always false

Replacing these conditions with constants yields:

```
(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

Removing unnecessary `TRUE` and `FALSE` constants yields:

```
(key1 < 'abc') OR (key1 < 'bar')
```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

```
(key1 < 'bar')
```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested `AND/OR` constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

MySQL does not support merging multiple ranges for the `range` access method for spatial indexes. To work around this limitation, you can use a `UNION` with identical `SELECT` statements, except that you put each spatial predicate in a different `SELECT`.

Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

| <code>key_part1</code> | <code>key_part2</code> | <code>key_part3</code> |
|------------------------|------------------------|------------------------|
| NULL | 1 | 'abc' |
| NULL | 1 | 'xyz' |
| NULL | 2 | 'foo' |
| 1 | 1 | 'abc' |
| 1 | 1 | 'xyz' |
| 1 | 2 | 'abc' |
| 2 | 1 | 'aaa' |

The condition `key_part1 = 1` defines this interval:

```
(1,-inf,-inf) <= (key_part1,key_part2,key_part3) < (1,+inf,+inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For [HASH](#) indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

```
key_part1 cmp const1
AND key_part2 cmp const2
AND ...
AND key_partN cmp constN;
```

Here, `const1`, `const2`, ... are constants, `cmp` is one of the `=`, `<=>`, or `IS NULL` comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part [HASH](#) index:

```
key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
```

For the definition of what is considered to be a constant, see [Range Access Method for Single-Part Indexes](#).

- For a [BTREE](#) index, an interval might be usable for conditions combined with `AND`, where each condition compares a key part with a constant value using `=`, `<=>`, `IS NULL`, `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE 'pattern'` (where `'pattern'` does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` or `!=` is used).

The optimizer attempts to use additional key parts to determine the interval as long as the comparison operator is `=`, `<=>`, or `IS NULL`. If the operator is `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE`, the optimizer uses it but considers no more key parts. For the following expression, the optimizer uses `=` from the first comparison. It also uses `>=` from the second comparison but considers no further key parts and does not use the third comparison for interval construction:

```
key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
```

The single interval is:

```
('foo',10,-inf) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)
```

It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value `('foo', 11, 0)`, which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with `OR`, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with `AND`, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

```
(key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)
```

The intervals are:

```
(1,-inf) < (key_part1,key_part2) < (1,2)
(5,-inf) < (key_part1,key_part2)
```

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The `key_len` column in the `EXPLAIN` output indicates the maximum length of the key prefix used.

In some cases, `key_len` may indicate that a key part was used, but that might be not what you would expect. Suppose that `key_part1` and `key_part2` can be `NULL`. Then the `key_len` column displays two key part lengths for the following condition:

```
key_part1 >= 1 AND key_part2 < 2
```

But, in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

For a description of how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index, see [Range Access Method for Single-Part Indexes](#). Analogous steps are performed for range conditions on multiple-part indexes.

8.2.1.3 Index Merge Optimization

The *Index Merge* access method retrieves rows with multiple `range` scans and merges their results into one. This access method merges index scans from a single table only, not scans across multiple tables. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans.

Example queries for which Index Merge may be used:

```
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;

SELECT * FROM tbl_name
  WHERE (key1 = 10 OR key2 = 20) AND non_key = 30;

SELECT * FROM t1, t2
  WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
     AND t2.key1 = t1.some_col1;

SELECT * FROM t1, t2
  WHERE t1.key1 = 1
     AND (t2.key1 = t1.some_col1 OR t2.key2 = t1.some_col2);
```

Note

The Index Merge optimization algorithm has the following known limitations:

- If your query has a complex `WHERE` clause with deep `AND/OR` nesting and MySQL does not choose the optimal plan, try distributing terms using the following identity transformations:

```
(x AND y) OR z => (x OR z) AND (y OR z)
(x OR y) AND z => (x AND z) OR (y AND z)
```

- Index Merge is not applicable to full-text indexes.
- If a range scan is possible on some key, the optimizer will not consider using Index Merge Union or Index Merge Sort-Union algorithms. For example, consider this query:

```
SELECT * FROM t1 WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
```

For this query, two plans are possible:

- An Index Merge scan using the `(goodkey1 < 10 OR goodkey2 < 20)` condition.
- A range scan using the `badkey < 30` condition.

■ However, the optimizer considers only the second plan.

In `EXPLAIN` output, the Index Merge method appears as `index_merge` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

The Index Merge access method has several algorithms, which are displayed in the `Extra` field of `EXPLAIN` output:

- `Using intersect(...)`
- `Using union(...)`
- `Using sort_union(...)`

The following sections describe these algorithms in greater detail. The optimizer chooses between different possible Index Merge algorithms and other access methods based on cost estimates of the various available options.

Use of Index Merge is subject to the value of the `index_merge`, `index_merge_intersection`, `index_merge_union`, and `index_merge_sort_union` flags of the `optimizer_switch` system variable. See [Section 8.9.2, “Switchable Optimizations”](#). By default, all those flags are `on`. To enable only certain algorithms, set `index_merge` to `off`, and enable only such of the others as should be permitted.

- [Index Merge Intersection Access Algorithm](#)
- [Index Merge Union Access Algorithm](#)
- [Index Merge Sort-Union Access Algorithm](#)

Index Merge Intersection Access Algorithm

This access algorithm is applicable when a `WHERE` clause is converted to several range conditions on different keys combined with `AND`, and each condition is one of the following:

- An *N*-part expression of this form, where the index has exactly *N* parts (that is, all index parts are covered):

```
key_part1 = const1 AND key_part2 = const2 ... AND key_partN = constN
```

- Any range condition over the primary key of an `InnoDB` table.

Examples:

```
SELECT * FROM innodb_table
  WHERE primary_key < 10 AND key_coll = 20;

SELECT * FROM tbl_name
  WHERE key1_part1 = 1 AND key1_part2 = 2 AND key2 = 2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (`EXPLAIN` output contains `Using index` in `Extra` field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1 = 1 AND key2 = 1;
```

If the used indexes do not cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over the primary key of an [InnoDB](#) table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

Index Merge Union Access Algorithm

The criteria for this algorithm are similar to those for the Index Merge intersection algorithm. The algorithm is applicable when the table's `WHERE` clause is converted to several range conditions on different keys combined with `OR`, and each condition is one of the following:

- An N -part expression of this form, where the index has exactly N parts (that is, all index parts are covered):

```
key_part1 = const1 AND key_part2 = const2 ... AND key_partN = constN
```

- Any range condition over a primary key of an [InnoDB](#) table.
- A condition for which the Index Merge intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1
  WHERE key1 = 1 OR key2 = 2 OR key3 = 3;

SELECT * FROM innodb_table
  WHERE (key1 = 1 AND key2 = 2)
  OR (key3 = 'foo' AND key4 = 'bar') AND key5 = 5;
```

Index Merge Sort-Union Access Algorithm

This access algorithm is applicable when the `WHERE` clause is converted to several range conditions combined by `OR`, but the Index Merge union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name
  WHERE key_col1 < 10 OR key_col2 < 20;

SELECT * FROM tbl_name
  WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col = 30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

8.2.1.4 Engine Condition Pushdown Optimization

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the [NDB](#) storage engine.

For NDB Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster's data nodes and the MySQL server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that an NDB Cluster table is defined as follows:

```
CREATE TABLE t1 (
  a INT,
  b INT,
  KEY(a)
) ENGINE=NDB;
```

Condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

```
SELECT a, b FROM t1 WHERE b = 10;
```

The use of condition pushdown can be seen in the output of [EXPLAIN](#):

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE b = 10\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
      type: ALL
possible_keys: NULL
      key: NULL
     key_len: NULL
      ref: NULL
      rows: 10
     Extra: Using where with pushed condition
```

However, condition pushdown *cannot* be used with either of these two queries:

```
SELECT a,b FROM t1 WHERE a = 10;
SELECT a,b FROM t1 WHERE b + 1 = 10;
```

Condition pushdown is not applicable to the first query because an index exists on column [a](#). (An index access method would be more efficient and so would be chosen in preference to condition pushdown.) Condition pushdown cannot be employed for the second query because the comparison involving the nonindexed column [b](#) is indirect. (However, condition pushdown could be applied if you were to reduce [b + 1 = 10](#) to [b = 9](#) in the [WHERE](#) clause.)

Condition pushdown may also be employed when an indexed column is compared with a constant using a [>](#) or [<](#) operator:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
      type: range
possible_keys: a
      key: a
     key_len: 5
      ref: NULL
      rows: 2
     Extra: Using where with pushed condition
```

Other supported comparisons for condition pushdown include the following:

- `column [NOT] LIKE pattern`
`pattern` must be a string literal containing the pattern to be matched; for syntax, see [Section 12.7.1, “String Comparison Functions and Operators”](#).
- `column IS [NOT] NULL`
- `column IN (value_list)`
 Each item in the `value_list` must be a constant, literal value.
- `column BETWEEN constant1 AND constant2`
`constant1` and `constant2` must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Engine condition pushdown is enabled by default. To disable it at server startup, set the `optimizer_switch` system variable. For example, in a `my.cnf` file, use these lines:

```
[mysqld]
optimizer_switch=engine_condition_pushdown=off
```

At runtime, disable condition pushdown like this:

```
SET optimizer_switch='engine_condition_pushdown=off';
```

Limitations. Condition pushdown is subject to the following limitations:

- Condition pushdown is supported only by the [NDB](#) storage engine.
- Columns may be compared with constants only; however, this includes expressions which evaluate to constant values.
- Columns used in comparisons cannot be of any of the [BLOB](#) or [TEXT](#) types. This exclusion extends to [BIT](#) and [ENUM](#) columns as well.
- A string value to be compared with a column must use the same collation as the column.
- Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use extended [EXPLAIN](#) output to determine which conditions are actually pushed down. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).

8.2.1.5 Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

- [Nested-Loop Join Algorithm](#)
- [Block Nested-Loop Join Algorithm](#)

Nested-Loop Join Algorithm

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables `t1`, `t2`, and `t3` is to be executed using the following join types:

| Table | Join Type |
|-------|-----------|
| t1 | range |
| t2 | ref |
| t3 | ALL |

If a simple NLJ algorithm is used, the join is processed like this:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    for each row in t3 {
      if row satisfies join conditions, send to client
    }
  }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, it typically reads tables processed in the inner loops many times.

Block Nested-Loop Join Algorithm

A Block Nested-Loop (BNL) join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared

against all 10 rows in the buffer. This reduces by an order of magnitude the number of times the inner table must be read.

MySQL join buffering has these characteristics:

- Join buffering can be used when the join is of type [ALL](#) or [index](#) (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or [range](#).
- A join buffer is never allocated for the first nonconstant table, even if it would be of type [ALL](#) or [index](#).
- Only columns of interest to a join are stored in its join buffer, not whole rows.
- The `join_buffer_size` system variable determines the size of each join buffer used to process a query.
- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.
- A join buffer is allocated prior to executing the join and freed after the query is done.

For the example join described previously for the NLJ algorithm (without buffering), the join is done as follows using join buffering:

```

for each row in t1 matching range {
  for each row in t2 matching reference key {
    store used columns from t1, t2 in join buffer
    if buffer is full {
      for each row in t3 {
        for each t1, t2 combination in join buffer {
          if row satisfies join conditions, send to client
        }
      }
      empty join buffer
    }
  }
}

if buffer is not empty {
  for each row in t3 {
    for each t1, t2 combination in join buffer {
      if row satisfies join conditions, send to client
    }
  }
}
    
```

If S is the size of each stored $t1$, $t2$ combination in the join buffer and C is the number of combinations in the buffer, the number of times table $t3$ is scanned is:

$$(S * C) / \text{join_buffer_size} + 1$$

The number of $t3$ scans decreases as the value of `join_buffer_size` increases, up to the point when `join_buffer_size` is large enough to hold all previous row combinations. At that point, no speed is gained by making it larger.

8.2.1.6 Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in [Section 13.2.9.2, “JOIN Clause”](#).

The syntax of `table_factor` is extended in comparison with the SQL Standard. The latter accepts only `table_reference`, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of `table_reference` items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
```

```
ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

Is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, `CROSS JOIN` is syntactically equivalent to `INNER JOIN`; they can replace each other. In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause; `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. Consider this join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
ON t1.a=t2.a
```

After removing parentheses and grouping operations to the left, that join expression transforms into this expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables `t1`, `t2`, and `t3` have the following state:

- Table `t1` contains rows (1), (2)
- Table `t2` contains row (1,101)
- Table `t3` contains row (101)

In this case, the first expression returns a result set including the rows (1,1,101,101), (2,NULL,NULL,NULL), whereas the second expression returns the rows (1,1,101,101), (2,NULL,NULL,101):

```
mysql> SELECT *
FROM t1
LEFT JOIN
(t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
ON t1.a=t2.a;
+-----+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | NULL |
+-----+-----+-----+-----+

mysql> SELECT *
FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
LEFT JOIN t3
ON t2.b=t3.b OR t2.b IS NULL;
+-----+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | 101 |
+-----+-----+-----+-----+
```

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3
```

For the given table states, the two expressions return different sets of rows:

```
mysql> SELECT *
      FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
+-----+-----+-----+-----+
| a     | a     | b     | b     |
+-----+-----+-----+-----+
| 1     | 1     | 101   | 101   |
| 2     | NULL  | NULL  | NULL  |
+-----+-----+-----+-----+

mysql> SELECT *
      FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
+-----+-----+-----+-----+
| a     | a     | b     | b     |
+-----+-----+-----+-----+
| 1     | 1     | 101   | 101   |
| 2     | NULL  | NULL  | 101   |
+-----+-----+-----+-----+
```

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```
(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)
```

Is equivalent to this expression for any tables `t1,t2,t3` and any condition `P` over attributes `t2.b` and `t3.b`:

```
t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)
```

Whenever the order of execution of join operations in a join expression (*joined_table*) is not from left to right, we talk about nested joins. Consider the following queries:

```
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
      WHERE t1.a > 1

SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
      WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3
```

In the first query, the nested join is formed with a left join operation. In the second query, it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. In our extended syntax, the parentheses in `(t2, t3)` of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because `LEFT JOIN` and `ON` play the role of the left and right delimiters for the expression `(t2,t3)`.

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed and joins evaluated left to right. In fact, tables can be evaluated in any order.

- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall the algorithm by which the nested-loop join executes a query (see [Section 8.2.1.5, “Nested-Loop Join Algorithms”](#)). Suppose that a join query over 3 tables `T1`, `T2`, `T3` has this form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
           INNER JOIN T3 ON P2(T2,T3)
WHERE P(T1,T2,T3)
```

Here, `P1(T1, T2)` and `P2(T2, T3)` are some join conditions (on expressions), whereas `P(T1, T2, T3)` is a condition over columns of tables `T1`, `T2`, `T3`.

The nested-loop join algorithm would execute this query in the following manner:

```
FOR each row t1 in T1 {
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

The notation `t1 || t2 || t3` indicates a row constructed by concatenating the columns of rows `t1`, `t2`, and `t3`. In some of the following examples, `NULL` where a table name appears means a row in which `NULL` is used for each column of that table. For example, `t1 || t2 || NULL` indicates a row constructed by concatenating the columns of rows `t1` and `t2`, and `NULL` for each column of `t3`. Such a row is said to be `NULL`-complemented.

Now consider a query with nested outer joins:

```
SELECT * FROM T1 LEFT JOIN
           (T2 LEFT JOIN T3 ON P2(T2,T3))
           ON P1(T1,T2)
WHERE P(T1,T2,T3)
```

For this query, modify the nested-loop pattern to obtain:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f2=TRUE;
    }
    f1=TRUE;
  }
  IF (!f2) {
    IF P(t1,t2,NULL) {
      t:=t1||t2||NULL; OUTPUT t;
    }
    f1=TRUE;
  }
}
IF (!f1) {
  IF P(t1,NULL,NULL) {
    t:=t1||NULL||NULL; OUTPUT t;
  }
}
```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by `NULL` values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In the example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

For the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```
FOR each row t3 in T3 {
  FOR each row t2 in T2 such that P2(t2,t3) {
    FOR each row t1 in T1 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

For queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer evaluates two different nestings. In both nestings, `T1` must be processed in the outer loop because it is used in an outer join. `T2` and `T3` are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, `T2` and `T3` can be processed in either order.

```
SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)
```

One nesting evaluates `T2`, then `T3`:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t1,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f1:=TRUE
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}
```

The other nesting evaluates `T3`, then `T2`:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t3 in T3 such that P2(t1,t3) {
    FOR each row t2 in T2 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f1:=TRUE
    }
  }
  IF (!f1) {
```

```

    IF P(t1,NULL,NULL) {
        t:=t1|NULL|NULL; OUTPUT t;
    }
}

```

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our `WHERE` condition `P(T1, T2, T3)` can be represented by a conjunctive formula:

```
P(T1,T2,T2) = C1(T1) AND C2(T2) AND C3(T3).
```

In this case, MySQL actually uses the following nested-loop algorithm for the execution of the query with inner joins:

```

FOR each row t1 in T1 such that C1(t1) {
    FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2) {
        FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
}

```

You see that each of the conjuncts `C1(T1)`, `C2(T2)`, `C3(T3)` are pushed out of the most inner loop to the most outer loop where it can be evaluated. If `C1(T1)` is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table `T1` passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the `WHERE` condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we must introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

Recall this example with outer joins:

```
P(T1,T2,T3)=C1(T1) AND C(T2) AND C3(T3)
```

For that example, the nested-loop algorithm using guarded pushed-down conditions looks like this:

```

FOR each row t1 in T1 such that C1(t1) {
    BOOL f1:=FALSE;
    FOR each row t2 in T2
        such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
        BOOL f2:=FALSE;
        FOR each row t3 in T3
            such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
            IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
                t:=t1||t2||t3; OUTPUT t;
            }
            f2=TRUE;
            f1=TRUE;
        }
        IF (!f2) {
            IF (f1?TRUE:C2(t2) && P(t1,t2,NULL)) {
                t:=t1||t2||NULL; OUTPUT t;
            }
            f1=TRUE;
        }
    }
    IF (!f1 && P(t1,NULL,NULL)) {
        t:=t1|NULL|NULL; OUTPUT t;
    }
}

```

In general, pushed-down predicates can be extracted from join conditions such as `P1(T1, T2)` and `P(T2, T3)`. In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the `NULL`-complemented row generated by the corresponding outer join operation.

Access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the `WHERE` condition.

8.2.1.7 Outer Join Optimization

Outer joins include `LEFT JOIN` and `RIGHT JOIN`.

MySQL implements an `A LEFT JOIN B join_specification` as follows:

- Table `B` is set to depend on table `A` and all tables on which `A` depends.
- Table `A` is set to depend on all tables (except `B`) that are used in the `LEFT JOIN` condition.
- The `LEFT JOIN` condition is used to decide how to retrieve rows from table `B`. (In other words, any condition in the `WHERE` clause is not used.)
- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependency, an error occurs.
- All standard `WHERE` optimizations are performed.
- If there is a row in `A` that matches the `WHERE` clause, but there is no row in `B` that matches the `ON` condition, an extra `B` row is generated with all columns set to `NULL`.
- If you use `LEFT JOIN` to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the `WHERE` part, where `col_name` is a column that is declared as `NOT NULL`, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the `LEFT JOIN` condition.

The `RIGHT JOIN` implementation is analogous to that of `LEFT JOIN` with the table roles reversed. Right joins are converted to equivalent left joins, as described in [Section 8.2.1.8, “Outer Join Simplification”](#).

For a `LEFT JOIN`, if the `WHERE` condition is always false for the generated `NULL` row, the `LEFT JOIN` is changed to an inner join. For example, the `WHERE` clause would be false in the following query if `t2.column1` were `NULL`:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to an inner join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

Now the optimizer can use table `t2` before table `t1` if doing so would result in a better query plan. To provide a hint about the table join order, use `STRAIGHT_JOIN`; see [Section 13.2.9, “SELECT Statement”](#).

8.2.1.8 Outer Join Simplification

Table expressions in the `FROM` clause of a query are simplified in many cases.

At the parser stage, queries with right outer join operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed such that this right join:

```
(T1, ...) RIGHT JOIN (T2, ...) ON P(T1, ..., T2, ...)
```

Becomes this equivalent left join:

```
(T2, ...) LEFT JOIN (T1, ...) ON P(T1, ..., T2, ...)
```

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1, T2)` are replaced by the list `T1, T2, P(T1, T2)` being joined as a conjunct to the `WHERE` condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for outer join operations, it takes into consideration only plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer choices are limited because only such plans enable outer joins to be executed using the nested-loop algorithm.

Consider a query of this form, where `R(T2)` greatly narrows the number of matching rows from table `T2`:

```
SELECT * T1 LEFT JOIN T2 ON P1(T1, T2)
WHERE P(T1, T2) AND R(T2)
```

If the query is executed as written, the optimizer has no choice but to access the less-restricted table `T1` before the more-restricted table `T2`, which may produce a very inefficient execution plan.

Instead, MySQL converts the query to a query with no outer join operation if the `WHERE` condition is null-rejected. (That is, it converts the outer join to an inner join.) A condition is said to be null-rejected for an outer join operation if it evaluates to `FALSE` or `UNKNOWN` for any `NULL`-complemented row generated for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected because they cannot be true for any `NULL`-complemented row (with `T2` columns set to `NULL`):

```
T2.B IS NOT NULL
T2.B > 3
T2.C <= T1.C
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected because they might be true for a `NULL`-complemented row:

```
T2.B IS NULL
T1.B < 3 OR T2.B IS NOT NULL
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple:

- It is of the form `A IS NOT NULL`, where `A` is an attribute of any of the inner tables
- It is a predicate containing a reference to an inner table that evaluates to `UNKNOWN` when one of its arguments is `NULL`
- It is a conjunction containing a null-rejected condition as a conjunct
- It is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In this query, the `WHERE` condition is null-rejected for the second outer join operation but is not null-rejected for the first one:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
```

```

LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0

```

If the `WHERE` condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, in the preceding query, the second outer join is null-rejected and can be replaced by an inner join:

```

SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0

```

For the original query, the optimizer evaluates only plans compatible with the single table-access order `T1, T2, T3`. For the rewritten query, it additionally considers the access order `T3, T1, T2`.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```

SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0

```

Is first converted to the query:

```

SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0

```

Which is equivalent to the query:

```

SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B

```

The remaining outer join operation can also be replaced by an inner join because the condition `T3.B=T2.B` is null-rejected. This results in a query with no outer joins at all:

```

SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B

```

Sometimes the optimizer succeeds in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```

SELECT * FROM T1 LEFT JOIN
(T2 LEFT JOIN T3 ON T3.B=T2.B)
ON T2.A=T1.A
WHERE T3.C > 0

```

Is converted to:

```

SELECT * FROM T1 LEFT JOIN
(T2 INNER JOIN T3 ON T3.B=T2.B)
ON T2.A=T1.A
WHERE T3.C > 0

```

That can be rewritten only to the form still containing the embedding outer join operation:

```

SELECT * FROM T1 LEFT JOIN
(T2, T3)
ON (T2.A=T1.A AND T3.B=T2.B)
WHERE T3.C > 0

```

Any attempt to convert an embedded outer join operation in a query must take into account the join condition for the embedding outer join together with the `WHERE` condition. In this query, the `WHERE` condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join `T2.A=T1.A AND T3.C=T1.C` is null-rejected:

```
SELECT * FROM T1 LEFT JOIN
      (T2 LEFT JOIN T3 ON T3.B=T2.B)
      ON T2.A=T1.A AND T3.C=T1.C
WHERE T3.D > 0 OR T1.D > 0
```

Consequently, the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
      (T2, T3)
      ON T2.A=T1.A AND T3.C=T1.C AND T3.B=T2.B
WHERE T3.D > 0 OR T1.D > 0
```

8.2.1.9 IS NULL Optimization

MySQL can perform the same optimization on `col_name IS NULL` that it can use for `col_name = constant_value`. For example, MySQL can use indexes and ranges to search for `NULL` with `IS NULL`.

Examples:

```
SELECT * FROM tbl_name WHERE key_col IS NULL;

SELECT * FROM tbl_name WHERE key_col <=> NULL;

SELECT * FROM tbl_name
WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a `WHERE` clause includes a `col_name IS NULL` condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway (for example, if it comes from a table on the right side of a `LEFT JOIN`).

MySQL can also optimize the combination `col_name = expr OR col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` when this optimization is used.

This optimization can handle one `IS NULL` for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;

SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;

SELECT * FROM t1, t2
WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;

SELECT * FROM t1, t2
WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);

SELECT * FROM t1, t2
WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

The optimization can handle only one `IS NULL` level. In the following query, MySQL uses key lookups only on the expression `(t1.a=t2.a AND t2.a IS NULL)` and is not able to use the key part on `b`:

```
SELECT * FROM t1, t2
WHERE (t1.a=t2.a AND t2.a IS NULL)
OR (t1.b=t2.b AND t2.b IS NULL);
```

8.2.1.10 ORDER BY Optimization

This section describes when MySQL can use an index to satisfy an `ORDER BY` clause, the `filesort` operation used when an index cannot be used, and execution plan information available from the optimizer about `ORDER BY`.

An `ORDER BY` with and without `LIMIT` may return rows in different orders, as discussed in Section 8.2.1.13, “LIMIT Query Optimization”.

- [Use of Indexes to Satisfy ORDER BY](#)
- [Use of filesort to Satisfy ORDER BY](#)
- [Influencing ORDER BY Optimization](#)
- [ORDER BY Execution Plan Information Available](#)

Use of Indexes to Satisfy ORDER BY

In some cases, MySQL may use an index to satisfy an `ORDER BY` clause and avoid the extra sorting involved in performing a `filesort` operation.

The index may also be used even if the `ORDER BY` does not match the index exactly, as long as all unused portions of the index and all extra `ORDER BY` columns are constants in the `WHERE` clause. If the index does not contain all columns accessed by the query, the index is used only if index access is cheaper than other access methods.

Assuming that there is an index on `(key_part1, key_part2)`, the following queries may use the index to resolve the `ORDER BY` part. Whether the optimizer actually does so depends on whether reading the index is more efficient than a table scan if columns not in the index must also be read.

- In this query, the index on `(key_part1, key_part2)` enables the optimizer to avoid sorting:

```
SELECT * FROM t1
ORDER BY key_part1, key_part2;
```

However, the query uses `SELECT *`, which may select more columns than `key_part1` and `key_part2`. In that case, scanning an entire index and looking up table rows to find columns not in the index may be more expensive than scanning the table and sorting the results. If so, the optimizer probably will not use the index. If `SELECT *` selects only the index columns, the index will be used and sorting avoided.

If `t1` is an InnoDB table, the table primary key is implicitly part of the index, and the index can be used to resolve the `ORDER BY` for this query:

```
SELECT pk, key_part1, key_part2 FROM t1
ORDER BY key_part1, key_part2;
```

- In this query, `key_part1` is constant, so all rows accessed through the index are in `key_part2` order, and an index on `(key_part1, key_part2)` avoids sorting if the `WHERE` clause is selective enough to make an index range scan cheaper than a table scan:

```
SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2;
```

- In the next two queries, whether the index is used is similar to the same queries without `DESC` shown previously:

```
SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
WHERE key_part1 = constant
```

```
ORDER BY key_part2 DESC;
```

- In the next two queries, *key_part1* is compared to a constant. The index will be used if the `WHERE` clause is selective enough to make an index range scan cheaper than a table scan:

```
SELECT * FROM t1
  WHERE key_part1 > constant
  ORDER BY key_part1 ASC;

SELECT * FROM t1
  WHERE key_part1 < constant
  ORDER BY key_part1 DESC;
```

- In the next query, the `ORDER BY` does not name *key_part1*, but all rows selected have a constant *key_part1* value, so the index can still be used:

```
SELECT * FROM t1
  WHERE key_part1 = constant1 AND key_part2 > constant2
  ORDER BY key_part2;
```

In some cases, MySQL *cannot* use indexes to resolve the `ORDER BY`, although it may still use indexes to find the rows that match the `WHERE` clause. Examples:

- The query uses `ORDER BY` on different indexes:

```
SELECT * FROM t1 ORDER BY key1, key2;
```

- The query uses `ORDER BY` on nonconsecutive parts of an index:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1_part1, key1_part3;
```

- The query mixes `ASC` and `DESC`:

```
SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 ASC;
```

- The index used to fetch the rows differs from the one used in the `ORDER BY`:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
```

- The query uses `ORDER BY` with an expression that includes terms other than the index column name:

```
SELECT * FROM t1 ORDER BY ABS(key);
SELECT * FROM t1 ORDER BY -key;
```

- The query joins many tables, and the columns in the `ORDER BY` are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the `EXPLAIN` output that does not have a `const` join type.)
- The query has different `ORDER BY` and `GROUP BY` expressions.
- There is an index on only a prefix of a column named in the `ORDER BY` clause. In this case, the index cannot be used to fully resolve the sort order. For example, if only the first 10 bytes of a `CHAR(20)` column are indexed, the index cannot distinguish values past the 10th byte and a `filesort` is needed.
- The index does not store rows in order. For example, this is true for a `HASH` index in a `MEMORY` table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column `t1.a` is indexed. In this statement, the name of the column in the select list is `a`. It refers to `t1.a`, as does the reference to `a` in the `ORDER BY`, so the index on `t1.a` can be used:

```
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also `a`, but it is the alias name. It refers to `ABS(a)`, as does the reference to `a` in the `ORDER BY`, so the index on `t1.a` cannot be used:

```
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the `ORDER BY` refers to a name that is not the name of a column in the select list. But there is a column in `t1` named `a`, so the `ORDER BY` refers to `t1.a` and the index on `t1.a` can be used. (The resulting sort order may be completely different from the order for `ABS(a)`, of course.)

```
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

By default, MySQL sorts `GROUP BY col1, col2, ...` queries as if you also included `ORDER BY col1, col2, ...` in the query. If you include an explicit `ORDER BY` clause that contains the same column list, MySQL optimizes it away without any speed penalty, although the sorting still occurs.

If a query includes `GROUP BY` but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying `ORDER BY NULL`. For example:

```
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```

The optimizer may still choose to use sorting to implement grouping operations. `ORDER BY NULL` suppresses sorting of the result, not prior sorting done by grouping operations to determine the result.

Note

`GROUP BY` implicitly sorts by default (that is, in the absence of `ASC` or `DESC` designators for `GROUP BY` columns), but relying on implicit `GROUP BY` sorting is deprecated. To produce a given sort order, use explicit `ASC` or `DESC` designators for `GROUP BY` columns or provide an `ORDER BY` clause. `GROUP BY` sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.

Use of filesort to Satisfy ORDER BY

If an index cannot be used to satisfy an `ORDER BY` clause, MySQL performs a `filesort` operation that reads table rows and sorts them. A `filesort` constitutes an extra sorting phase in query execution.

To obtain memory for `filesort` operations, the optimizer allocates a fixed amount of `sort_buffer_size` bytes up front. Individual sessions can change the session value of this variable as desired to avoid excessive memory use, or to allocate more memory as necessary.

A `filesort` operation uses temporary disk files as necessary if the result set is too large to fit in memory. Some types of queries are particularly suited to completely in-memory `filesort` operations. For example, the optimizer can use `filesort` to efficiently handle in memory, without temporary files, the `ORDER BY` operation for queries (and subqueries) of the following form:

```
SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M,]N;
```

Such queries are common in web applications that display only a few rows from a larger result set. Examples:

```
SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;
SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;
```

Influencing ORDER BY Optimization

For slow `ORDER BY` queries for which `filesort` is not used, try lowering the `max_length_for_sort_data` system variable to a value that is appropriate to trigger a `filesort`.

(A symptom of setting the value of this variable too high is a combination of high disk activity and low CPU activity.)

To increase `ORDER BY` speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, try the following strategies:

- Increase the `sort_buffer_size` variable value. Ideally, the value should be large enough for the entire result set to fit in the sort buffer (to avoid writes to disk and merge passes), but at minimum the value must be large enough to accommodate 15 tuples. (Up to 15 temporary disk files are merged and there must be room in memory for at least one tuple per file.)

Take into account that the size of column values stored in the sort buffer is affected by the `max_sort_length` system variable value. For example, if tuples store values of long string columns and you increase the value of `max_sort_length`, the size of sort buffer tuples increases as well and may require you to increase `sort_buffer_size`. For column values calculated as a result of string expressions (such as those that invoke a string-valued function), the `filesort` algorithm cannot tell the maximum length of expression values, so it must allocate `max_sort_length` bytes for each tuple.

To monitor the number of merge passes (to merge temporary files), check the `Sort_merge_passes` status variable.

- Increase the `read_rnd_buffer_size` variable value so that more rows are read at a time.
- Use less RAM per row by declaring columns only as large as they need to be to hold the values stored in them. For example, `CHAR(16)` is better than `CHAR(200)` if values never exceed 16 characters.
- Change the `tmpdir` system variable to point to a dedicated file system with large amounts of free space. The variable value can list several paths that are used in round-robin fashion; you can use this feature to spread the load across several directories. Separate the paths by colon characters (:) on Unix and semicolon characters (;) on Windows. The paths should name directories in file systems located on different *physical* disks, not different partitions on the same disk.

ORDER BY Execution Plan Information Available

With `EXPLAIN` (see [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#)), you can check whether MySQL can use indexes to resolve an `ORDER BY` clause:

- If the `Extra` column of `EXPLAIN` output does not contain `Using filesort`, the index is used and a `filesort` is not performed.
- If the `Extra` column of `EXPLAIN` output contains `Using filesort`, the index is not used and a `filesort` is performed.

8.2.1.11 GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (as is true, for example, for a `BTREE` index, but not for a `HASH` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query through index access, as detailed in the following sections. The first method applies the grouping operation together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

In MySQL, `GROUP BY` is used for sorting, so the server may also apply `ORDER BY` optimizations to grouping. However, relying on implicit `GROUP BY` sorting is deprecated. See [Section 8.2.1.10, “ORDER BY Optimization”](#).

- [Loose Index Scan](#)
- [Tight Index Scan](#)

Loose Index Scan

The most efficient way to process `GROUP BY` is when an index is used to directly retrieve the grouping columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, `BTREE`). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all `WHERE` conditions. This access method considers only a fraction of the keys in an index, so it is called a *Loose Index Scan*. When there is no `WHERE` clause, a Loose Index Scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the `WHERE` clause contains range predicates (see the discussion of the `range` join type in [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#)), a Loose Index Scan looks up the first key of each group that satisfies the range conditions, and again reads the smallest possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The `GROUP BY` names only columns that form a leftmost prefix of the index and no other columns. (If, instead of `GROUP BY`, the query has a `DISTINCT` clause, all distinct attributes refer to columns that form a leftmost prefix of the index.) For example, if a table `t1` has an index on `(c1,c2,c3)`, Loose Index Scan is applicable if the query has `GROUP BY c1, c2`. It is not applicable if the query has `GROUP BY c2, c3` (the columns are not a leftmost prefix) or `GROUP BY c1, c2, c4` (`c4` is not in the index).
- The only aggregate functions used in the select list (if any) are `MIN()` and `MAX()`, and all of them refer to the same column. The column must be in the index and must immediately follow the columns in the `GROUP BY`.
- Any other parts of the index than those from the `GROUP BY` referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of `MIN()` or `MAX()` functions.
- For columns in the index, full column values must be indexed, not just a prefix. For example, with `c1 VARCHAR(20)`, `INDEX (c1(10))`, the index uses only a prefix of `c1` values and cannot be used for Loose Index Scan.

If Loose Index Scan is applicable to a query, the `EXPLAIN` output shows `Using index for group-by` in the `Extra` column.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The Loose Index Scan access method can be used for the following queries:

```
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;
```

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than `MIN()` or `MAX()`:

```
SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
```

- The columns in the `GROUP BY` clause do not form a leftmost prefix of the index:

```
SELECT c1, c2 FROM t1 GROUP BY c2, c3;
```

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant:

```
SELECT c1, c3 FROM t1 GROUP BY c1, c2;
```

Were the query to include `WHERE c3 = const`, Loose Index Scan could be used.

The Loose Index Scan access method can be applied to other forms of aggregate function references in the select list, in addition to the `MIN()` and `MAX()` references already supported:

- `AVG(DISTINCT)`, `SUM(DISTINCT)`, and `COUNT(DISTINCT)` are supported. `AVG(DISTINCT)` and `SUM(DISTINCT)` take a single argument. `COUNT(DISTINCT)` can have more than one column argument.
- There must be no `GROUP BY` or `DISTINCT` clause in the query.
- The Loose Index Scan limitations described previously still apply.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The Loose Index Scan access method can be used for the following queries:

```
SELECT COUNT(DISTINCT c1), SUM(DISTINCT c1) FROM t1;
```

```
SELECT COUNT(DISTINCT c1, c2), COUNT(DISTINCT c2, c1) FROM t1;
```

Tight Index Scan

A Tight Index Scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a Loose Index Scan are not met, it still may be possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, it is called a *Tight Index Scan*. With a Tight Index Scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there be a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If the `GROUP BY` result requires sorting, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The following queries do not work with the Loose Index Scan access method described previously, but still work with the Tight Index Scan access method.

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:

```
SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
```

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:

```
SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
```

8.2.1.12 DISTINCT Optimization

`DISTINCT` combined with `ORDER BY` needs a temporary table in many cases.

Because `DISTINCT` may use `GROUP BY`, learn how MySQL works with columns in `ORDER BY` or `HAVING` clauses that are not part of the selected columns. See [Section 12.17.3, “MySQL Handling of GROUP BY”](#).

In most cases, a `DISTINCT` clause can be considered as a special case of `GROUP BY`. For example, the following two queries are equivalent:

```
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;

SELECT c1, c2, c3 FROM t1
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to `GROUP BY` queries can be also applied to queries with a `DISTINCT` clause. Thus, for more details on the optimization possibilities for `DISTINCT` queries, see [Section 8.2.1.11, “GROUP BY Optimization”](#).

When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with `EXPLAIN`), MySQL stops reading from `t2` (for any particular row in `t1`) when it finds the first row in `t2`:

```
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

8.2.1.13 LIMIT Query Optimization

If you need only a specified number of rows from a result set, use a `LIMIT` clause in the query, rather than fetching the whole result set and throwing away the extra data.

MySQL sometimes optimizes a query that has a `LIMIT row_count` clause and no `HAVING` clause:

- If you select only a few rows with `LIMIT`, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.
- If you combine `LIMIT row_count` with `ORDER BY`, MySQL stops sorting as soon as it has found the first `row_count` rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the `LIMIT` clause are selected, and most or all of them are sorted, before the first `row_count` are found. After the initial rows have been found, MySQL does not sort any remainder of the result set.

One manifestation of this behavior is that an `ORDER BY` query with and without `LIMIT` may return rows in different order, as described later in this section.

- If you combine `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.
- In some cases, a `GROUP BY` can be resolved by reading the index in order (or doing a sort on the index), then calculating summaries until the index value changes. In this case, `LIMIT row_count` does not calculate any unnecessary `GROUP BY` values.
- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using `SQL_CALC_FOUND_ROWS`. In that case, the number of rows can be retrieved with `SELECT FOUND_ROWS()`. See [Section 12.15, “Information Functions”](#).
- `LIMIT 0` quickly returns an empty set. This can be useful for checking the validity of a query. It can also be employed to obtain the types of the result columns within applications that use a MySQL

API that makes result set metadata available. With the `mysql` client program, you can use the `--column-type-info` option to display result column types.

- If the server uses temporary tables to resolve a query, it uses the `LIMIT row_count` clause to calculate how much space is required.

If multiple rows have identical values in the `ORDER BY` columns, the server is free to return those rows in any order, and may do so differently depending on the overall execution plan. In other words, the sort order of those rows is nondeterministic with respect to the nonordered columns.

One factor that affects the execution plan is `LIMIT`, so an `ORDER BY` query with and without `LIMIT` may return rows in different orders. Consider this query, which is sorted by the `category` column but nondeterministic with respect to the `id` and `rating` columns:

```
mysql> SELECT * FROM ratings ORDER BY category;
+-----+-----+-----+
| id | category | rating |
+-----+-----+-----+
| 1 | 1 | 4.5 |
| 5 | 1 | 3.2 |
| 3 | 2 | 3.7 |
| 4 | 2 | 3.5 |
| 6 | 2 | 3.5 |
| 2 | 3 | 5.0 |
| 7 | 3 | 2.7 |
+-----+-----+-----+
```

Including `LIMIT` may affect order of rows within each `category` value. For example, this is a valid query result:

```
mysql> SELECT * FROM ratings ORDER BY category LIMIT 5;
+-----+-----+-----+
| id | category | rating |
+-----+-----+-----+
| 1 | 1 | 4.5 |
| 5 | 1 | 3.2 |
| 4 | 2 | 3.5 |
| 3 | 2 | 3.7 |
| 6 | 2 | 3.5 |
+-----+-----+-----+
```

In each case, the rows are sorted by the `ORDER BY` column, which is all that is required by the SQL standard.

If it is important to ensure the same row order with and without `LIMIT`, include additional columns in the `ORDER BY` clause to make the order deterministic. For example, if `id` values are unique, you can make rows for a given `category` value appear in `id` order by sorting like this:

```
mysql> SELECT * FROM ratings ORDER BY category, id;
+-----+-----+-----+
| id | category | rating |
+-----+-----+-----+
| 1 | 1 | 4.5 |
| 5 | 1 | 3.2 |
| 3 | 2 | 3.7 |
| 4 | 2 | 3.5 |
| 6 | 2 | 3.5 |
| 2 | 3 | 5.0 |
| 7 | 3 | 2.7 |
+-----+-----+-----+

mysql> SELECT * FROM ratings ORDER BY category, id LIMIT 5;
+-----+-----+-----+
| id | category | rating |
+-----+-----+-----+
| 1 | 1 | 4.5 |
| 5 | 1 | 3.2 |
| 3 | 2 | 3.7 |
+-----+-----+-----+
```

| | | |
|---|---|-----|
| 4 | 2 | 3.5 |
| 6 | 2 | 3.5 |

8.2.1.14 Function Call Optimization

MySQL functions are tagged internally as deterministic or nondeterministic. A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations. Examples of nondeterministic functions: `RAND()`, `UUID()`.

If a function is tagged nondeterministic, a reference to it in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join).

MySQL also determines when to evaluate functions based on types of arguments, whether the arguments are table columns or constant values. A deterministic function that takes a table column as argument must be evaluated whenever that column changes value.

Nondeterministic functions may affect query performance. For example, some optimizations may not be available, or more locking might be required. The following discussion uses `RAND()` but applies to other nondeterministic functions as well.

Suppose that a table `t` has this definition:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY, col_a VARCHAR(100));
```

Consider these two queries:

```
SELECT * FROM t WHERE id = POW(1,2);
SELECT * FROM t WHERE id = FLOOR(1 + RAND() * 49);
```

Both queries appear to use a primary key lookup because of the equality comparison against the primary key, but that is true only for the first of them:

- The first query always produces a maximum of one row because `POW()` with constant arguments is a constant value and is used for index lookup.
- The second query contains an expression that uses the nondeterministic function `RAND()`, which is not constant in the query but in fact has a new value for every row of table `t`. Consequently, the query reads every row of the table, evaluates the predicate for each row, and outputs all rows for which the primary key matches the random value. This might be zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The effects of nondeterminism are not limited to `SELECT` statements. This `UPDATE` statement uses a nondeterministic function to select rows to be modified:

```
UPDATE t SET col_a = some_expr WHERE id = FLOOR(1 + RAND() * 49);
```

Presumably the intent is to update at most a single row for which the primary key matches the expression. However, it might update zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The behavior just described has implications for performance and replication:

- Because a nondeterministic function does not produce a constant value, the optimizer cannot use strategies that might otherwise be applicable, such as index lookups. The result may be a table scan.
- `InnoDB` might escalate to a range-key lock rather than taking a single row lock for one matching row.
- Updates that do not execute deterministically are unsafe for replication.

The difficulties stem from the fact that the `RAND()` function is evaluated once for every row of the table. To avoid multiple function evaluations, use one of these techniques:

- Move the expression containing the nondeterministic function to a separate statement, saving the value in a variable. In the original statement, replace the expression with a reference to the variable, which the optimizer can treat as a constant value:

```
SET @keyval = FLOOR(1 + RAND() * 49);
UPDATE t SET col_a = some_expr WHERE id = @keyval;
```

- Assign the random value to a variable in a derived table. This technique causes the variable to be assigned a value, once, prior to its use in the comparison in the `WHERE` clause:

```
UPDATE t, (SELECT @keyval := FLOOR(1 + RAND() * 49)) AS dt
SET col_a = some_expr WHERE id = @keyval;
```

As mentioned previously, a nondeterministic expression in the `WHERE` clause might prevent optimizations and result in a table scan. However, it may be possible to partially optimize the `WHERE` clause if other expressions are deterministic. For example:

```
SELECT * FROM t WHERE partial_key=5 AND some_column=RAND();
```

If the optimizer can use `partial_key` to reduce the set of rows selected, `RAND()` is executed fewer times, which diminishes the effect of nondeterminism on optimization.

8.2.1.15 Row Constructor Expression Optimization

Row constructors permit simultaneous comparisons of multiple values. For example, these two statements are semantically equivalent:

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

In addition, the optimizer handles both expressions the same way.

The optimizer is less likely to use available indexes if the row constructor columns do not cover the prefix of an index. Consider the following table, which has a primary key on `(c1, c2, c3)`:

```
CREATE TABLE t1 (
  c1 INT, c2 INT, c3 INT, c4 CHAR(100),
  PRIMARY KEY(c1,c2,c3)
);
```

In this query, the `WHERE` clause uses all columns in the index. However, the row constructor itself does not cover an index prefix, with the result that the optimizer uses only `c1` (`key_len=4`, the size of `c1`):

```
mysql> EXPLAIN SELECT * FROM t1
  WHERE c1=1 AND (c2,c3) > (1,1)\G
***** 1. row *****
   id: 1
  select_type: SIMPLE
    table: t1
  partitions: NULL
     type: ref
possible_keys: PRIMARY
      key: PRIMARY
     key_len: 4
      ref: const
       rows: 3
  Extra: Using where
```

In such cases, rewriting the row constructor expression using an equivalent nonconstructor expression may result in more complete index use. For the given query, the row constructor and equivalent nonconstructor expressions are:

```
(c2,c3) > (1,1)
c2 > 1 OR ((c2 = 1) AND (c3 > 1))
```

Rewriting the query to use the nonconstructor expression results in the optimizer using all three columns in the index (`key_len=12`):

```
mysql> EXPLAIN SELECT * FROM t1
      WHERE c1 = 1 AND (c2 > 1 OR ((c2 = 1) AND (c3 > 1)))\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: t1
      partitions: NULL
      type: range
possible_keys: PRIMARY
      key: PRIMARY
      key_len: 12
      ref: NULL
      rows: 3
      Extra: Using where
```

Thus, for better results, avoid mixing row constructors with [AND/OR](#) expressions. Use one or the other.

8.2.1.16 Avoiding Full Table Scans

Frequently, a [full table scan](#) is a danger sign that a query can be speeded up significantly. For tables with more than a few rows, consider redesigning the query by adding an index for one or more of the columns tested in the [WHERE](#) clause. Put extra effort into avoiding table scans for queries that perform joins or reference foreign keys. If the nature of the data means there is no way to avoid reading all the rows, then it might not be practical to make the query faster, or making it faster might involve extensive restructuring of your tables that is beyond the scope of this section.

The output from [EXPLAIN](#) shows [ALL](#) in the [type](#) column when MySQL uses a table scan to resolve a query. This usually happens under the following conditions:

- The [ON](#) or [WHERE](#) clauses do not reference any indexed columns that the query can use. Consider adding an index, or refining those clauses to refer to an indexed column.
- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.
- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See [Section 8.2.1.1, “WHERE Clause Optimization”](#). For example, to query census data only for males or only for females, MySQL must read most of the data blocks in the table, so locating the rows through the index would add unnecessary overhead. If these reports are frequent or truly time-critical, and the table is huge, you might partition, shard, or create dimension tables using the relevant column.
- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably will do many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Minimize the [OR](#) keywords in your [WHERE](#) clauses. If there is no index that helps to locate the values on *both* sides of the [OR](#), any row could potentially be part of the result set, so all rows must be tested, and that requires a full table scan. If you have one index that helps to optimize one side of an [OR](#) query, and a different index that helps to optimize the other side, use a [UNION](#) operator to run separate fast queries and merge the results afterward.
- With tables that use the [MEMORY](#) storage engine, if you run queries that examine ranges of values (using operators such as [>](#), [<=](#), or [BETWEEN](#) on the indexed columns), create the index with the [USING BTREE](#) clause. The default ([USING HASH](#)) is fast for retrieving individual rows with an equality operator ([=](#) or [<=>](#)), but is much slower (requiring a full table scan) to examine a range of column values. A [MEMORY](#) table created with the [USING BTREE](#) clause is still fast for equality comparisons, so use that clause for your [MEMORY](#) tables that handle a variety of queries.

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See [Section 13.7.2.1, “ANALYZE TABLE Statement”](#).
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

See [Section 8.9.3, “Index Hints”](#).

- Start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See [Section 5.1.7, “Server System Variables”](#).

8.2.2 Subquery Optimization

Certain optimizations are applicable to comparisons that use the `IN` operator to test subquery results (or that use `=ANY`, which is equivalent). This section discusses these optimizations, particularly with regard to the challenges that `NULL` values present. The last part of the discussion suggests how you can help the optimizer.

Consider the following subquery comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression `outer_expr`, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression `inner_expr` is equal to `outer_expr`. This is done by pushing down an appropriate equality into the subquery’s `WHERE` clause to make it more restrictive. The converted comparison looks like this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

After the conversion, MySQL can use the pushed-down equality to limit the number of rows it must examine to evaluate the subquery.

More generally, a comparison of `N` values to a subquery that returns `N`-value rows is subject to the same conversion. If `oe_i` and `ie_i` represent corresponding outer and inner expression values, this subquery comparison:

```
(oe_1, ..., oe_N) IN
(SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

Becomes:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
AND oe_1 = ie_1
AND ...
AND oe_N = ie_N)
```

For simplicity, the following discussion assumes a single pair of outer and inner expression values.

The conversion just described has its limitations. It is valid only if we ignore possible `NULL` values. That is, the “pushdown” strategy works as long as both of these conditions are true:

- `outer_expr` and `inner_expr` cannot be `NULL`.
- You need not distinguish `NULL` from `FALSE` subquery results. If the subquery is a part of an `OR` or `AND` expression in the `WHERE` clause, MySQL assumes that you do not care.

When either or both of those conditions do not hold, optimization is more complex.

Suppose that `outer_expr` is known to be a non-NULL value but the subquery does not produce a row such that `outer_expr = inner_expr`. Then `outer_expr IN (SELECT ...)` evaluates as follows:

- `NULL`, if the `SELECT` produces any row where `inner_expr` is `NULL`
- `FALSE`, if the `SELECT` produces only non-NULL values or produces nothing

In this situation, the approach of looking for rows with `outer_expr = inner_expr` is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where `inner_expr` is `NULL`. Roughly speaking, the subquery can be converted to something like this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND
        (outer_expr=inner_expr OR inner_expr IS NULL))
```

The need to evaluate the extra `IS NULL` condition is why MySQL has the `ref_or_null` access method:

```
mysql> EXPLAIN
      SELECT outer_expr IN (SELECT t2.maybe_null_key
                          FROM t2, t3 WHERE ...)
      FROM t1;
***** 1. row *****
      id: 1
      select_type: PRIMARY
      table: t1
      ...
***** 2. row *****
      id: 2
      select_type: DEPENDENT SUBQUERY
      table: t2
      type: ref_or_null
possible_keys: maybe_null_key
      key: maybe_null_key
      key_len: 5
      ref: func
      rows: 2
      Extra: Using where; Using index
      ...
```

The `unique_subquery` and `index_subquery` subquery-specific access methods also have “or NULL” variants. However, they are not visible in `EXPLAIN` output, so you must use `EXPLAIN EXTENDED` followed by `SHOW WARNINGS` (note the `checking NULL` in the warning message):

```
mysql> EXPLAIN EXTENDED
      SELECT outer_expr IN (SELECT maybe_null_key FROM t2) FROM t1\G
***** 1. row *****
      id: 1
      select_type: PRIMARY
      table: t1
      ...
***** 2. row *****
      id: 2
      select_type: DEPENDENT SUBQUERY
      table: t2
      type: index_subquery
possible_keys: maybe_null_key
      key: maybe_null_key
      key_len: 5
      ref: func
      rows: 2
      Extra: Using index

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
      Code: 1003
      Message: select (`test`.`t1`.`outer_expr`,
```

```
((`test`.`t1`.`outer_expr`) in t2 on
maybe_null_key checking NULL)) AS `outer_expr` IN (SELECT
maybe_null_key FROM t2)` from `test`.`t1`
```

The additional `OR ... IS NULL` condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when `outer_expr` can be `NULL`. According to the SQL interpretation of `NULL` as “unknown value,” `NULL IN (SELECT inner_expr ...)` should evaluate to:

- `NULL`, if the `SELECT` produces any rows
- `FALSE`, if the `SELECT` produces no rows

For proper evaluation, it is necessary to be able to check whether the `SELECT` has produced any rows at all, so `outer_expr = inner_expr` cannot be pushed down into the subquery. This is a problem because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of `outer_expr`.

The optimizer chooses SQL compliance over speed, so it accounts for the possibility that `outer_expr` might be `NULL`:

- If `outer_expr` is `NULL`, to evaluate the following expression, it is necessary to execute the `SELECT` to determine whether it produces any rows:

```
NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

It is necessary to execute the original `SELECT` here, without any pushed-down equalities of the kind mentioned previously.

- On the other hand, when `outer_expr` is not `NULL`, it is absolutely essential that this comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

be converted to this expression that uses a pushed-down condition:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

Without this conversion, subqueries will be slow.

To solve the dilemma of whether or not to push down conditions into the subquery, the conditions are wrapped within “trigger” functions. Thus, an expression of the following form:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

is converted into:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
AND trigcond(outer_expr=inner_expr))
```

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

```
(oe_1, ..., oe_N) IN (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

and converts it to this expression:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
AND trigcond(oe_1=ie_1)
AND ...
AND trigcond(oe_N=ie_N)
)
```

Each `trigcond(X)` is a special function that evaluates to the following values:

- `X` when the “linked” outer expression `oe_i` is not `NULL`
- `TRUE` when the “linked” outer expression `oe_i` is `NULL`

Note

Trigger functions are *not* triggers of the kind that you create with `CREATE TRIGGER`.

Equalities that are wrapped within `trigcond()` functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any `trigcond(X)` to be an unknown function and ignore it. Triggered equalities can be used by those optimizations:

- Reference optimizations: `trigcond(X=Y [OR Y IS NULL])` can be used to construct `ref`, `eq_ref`, or `ref_or_null` table accesses.
- Index lookup-based subquery execution engines: `trigcond(X=Y)` can be used to construct `unique_subquery` or `index_subquery` accesses.
- Table-condition generator: If the subquery is a join of several tables, the triggered condition is checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the condition is turned off. This fallback strategy is always the same: Do a full table scan. In `EXPLAIN` output, the fallback shows up as `Full scan on NULL key` in the `Extra` column:

```
mysql> EXPLAIN SELECT t1.col1,
          t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1\G
***** 1. row *****
      id: 1
  select_type: PRIMARY
      table: t1
      ...
***** 2. row *****
      id: 2
  select_type: DEPENDENT SUBQUERY
      table: t2
      type: index_subquery
possible_keys: key1
      key: key1
      key_len: 5
      ref: func
      rows: 2
  Extra: Using where; Full scan on NULL key
```

If you run `EXPLAIN EXTENDED` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
***** 1. row *****
  Level: Note
  Code: 1003
Message: select `test`.`t1`.`col1` AS `col1`,
           <in_optimizer>(`test`.`t1`.`col1`,
           <exists>(<index_lookup>(<cache>(`test`.`t1`.`col1`) in t2
           on key1 checking NULL
           where (`test`.`t2`.`col2` = `test`.`t1`.`col2`) having
           trigcond(<is_not_null_test>(`test`.`t2`.`key1`)))) AS
           `t1.col1 IN (select t2.key1 from t2 where t2.col2=t1.col2)`
           from `test`.`t1`
```

The use of triggered conditions has some performance implications. A `NULL IN (SELECT ...)` expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy is to improve compliance, not speed).

For multiple-table subqueries, execution of `NULL IN (SELECT ...)` is particularly slow because the join optimizer does not optimize for the case where the outer expression is `NULL`. It assumes that subquery evaluations with `NULL` on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be `NULL` but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these suggestions:

- Declare a column as `NOT NULL` if it really is. This also helps other aspects of the optimizer by simplifying condition testing for the column.
- If you need not distinguish a `NULL` from `FALSE` subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:

```
outer_expr IN (SELECT inner_expr FROM ...)
```

with this expression:

```
(outer_expr IS NOT NULL) AND (outer_expr IN (SELECT inner_expr FROM ...))
```

Then `NULL IN (SELECT ...)` is never evaluated because MySQL stops evaluating `AND` parts as soon as the expression result is clear.

8.2.3 Optimizing INFORMATION_SCHEMA Queries

Applications that monitor databases may make frequent use of `INFORMATION_SCHEMA` tables. Certain types of queries for `INFORMATION_SCHEMA` tables can be optimized to execute more quickly. The goal is to minimize file operations (for example, scanning a directory or opening a table file) to collect the information that makes up these dynamic tables.

Note

Comparison behavior for database and table names in `INFORMATION_SCHEMA` queries might differ from what you expect. For details, see [Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”](#).

1) Try to use constant lookup values for database and table names in the `WHERE` clause

You can take advantage of this principle as follows:

- To look up databases or tables, use expressions that evaluate to a constant, such as literal values, functions that return a constant, or scalar subqueries.
- Avoid queries that use a nonconstant database name lookup value (or no lookup value) because they require a scan of the data directory to find matching database directory names.
- Within a database, avoid queries that use a nonconstant table name lookup value (or no lookup value) because they require a scan of the database directory to find matching table files.

This principle applies to the `INFORMATION_SCHEMA` tables shown in the following table, which shows the columns for which a constant lookup value enables the server to avoid a directory scan. For example, if you are selecting from `TABLES`, using a constant lookup value for `TABLE_SCHEMA` in the `WHERE` clause enables a data directory scan to be avoided.

| Table | Column to specify to avoid data directory scan | Column to specify to avoid database directory scan |
|-------------------------------|--|--|
| <code>COLUMNS</code> | <code>TABLE_SCHEMA</code> | <code>TABLE_NAME</code> |
| <code>KEY_COLUMN_USAGE</code> | <code>TABLE_SCHEMA</code> | <code>TABLE_NAME</code> |
| <code>PARTITIONS</code> | <code>TABLE_SCHEMA</code> | <code>TABLE_NAME</code> |

| Table | Column to specify to avoid data directory scan | Column to specify to avoid database directory scan |
|-------------------------|--|--|
| REFERENTIAL_CONSTRAINTS | CONSTRAINT_SCHEMA | TABLE_NAME |
| STATISTICS | TABLE_SCHEMA | TABLE_NAME |
| TABLES | TABLE_SCHEMA | TABLE_NAME |
| TABLE_CONSTRAINTS | TABLE_SCHEMA | TABLE_NAME |
| TRIGGERS | EVENT_OBJECT_SCHEMA | EVENT_OBJECT_TABLE |
| VIEWS | TABLE_SCHEMA | TABLE_NAME |

The benefit of a query that is limited to a specific constant database name is that checks need be made only for the named database directory. Example:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

Use of the literal database name `test` enables the server to check only the `test` database directory, regardless of how many databases there might be. By contrast, the following query is less efficient because it requires a scan of the data directory to determine which database names match the pattern `'test%'`:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA LIKE 'test%';
```

For a query that is limited to a specific constant table name, checks need be made only for the named table within the corresponding database directory. Example:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 't1';
```

Use of the literal table name `t1` enables the server to check only the files for the `t1` table, regardless of how many tables there might be in the `test` database. By contrast, the following query requires a scan of the `test` database directory to determine which table names match the pattern `'t%'`:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME LIKE 't%';
```

The following query requires a scan of the database directory to determine matching database names for the pattern `'test%'`, and for each matching database, it requires a scan of the database directory to determine matching table names for the pattern `'t%'`:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test%' AND TABLE_NAME LIKE 't%';
```

2) Write queries that minimize the number of table files that must be opened

For queries that refer to certain `INFORMATION_SCHEMA` table columns, several optimizations are available that minimize the number of table files that must be opened. Example:

```
SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

In this case, after the server has scanned the database directory to determine the names of the tables in the database, those names become available with no further file system lookups. Thus, `TABLE_NAME` requires no files to be opened. The `ENGINE` (storage engine) value can be determined by opening the table's `.frm` file, without touching other table files such as the `.MYD` or `.MYI` file.

Some values, such as `INDEX_LENGTH` for `MyISAM` tables, require opening the `.MYD` or `.MYI` file as well.

The file-opening optimization types are denoted thus:

- **SKIP_OPEN_TABLE**: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
- **OPEN_FRM_ONLY**: Only the table's `.frm` file need be opened.
- **OPEN_TRIGGER_ONLY**: Only the table's `.TRG` file need be opened.
- **OPEN_FULL_TABLE**: The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

The following list indicates how the preceding optimization types apply to `INFORMATION_SCHEMA` table columns. For tables and columns not named, none of the optimizations apply.

- **COLUMNS**: `OPEN_FRM_ONLY` applies to all columns
- **KEY_COLUMN_USAGE**: `OPEN_FULL_TABLE` applies to all columns
- **PARTITIONS**: `OPEN_FULL_TABLE` applies to all columns
- **REFERENTIAL_CONSTRAINTS**: `OPEN_FULL_TABLE` applies to all columns
- **STATISTICS**:

| Column | Optimization type |
|---------------|-------------------|
| TABLE_CATALOG | OPEN_FRM_ONLY |
| TABLE_SCHEMA | OPEN_FRM_ONLY |
| TABLE_NAME | OPEN_FRM_ONLY |
| NON_UNIQUE | OPEN_FRM_ONLY |
| INDEX_SCHEMA | OPEN_FRM_ONLY |
| INDEX_NAME | OPEN_FRM_ONLY |
| SEQ_IN_INDEX | OPEN_FRM_ONLY |
| COLUMN_NAME | OPEN_FRM_ONLY |
| COLLATION | OPEN_FRM_ONLY |
| CARDINALITY | OPEN_FULL_TABLE |
| SUB_PART | OPEN_FRM_ONLY |
| PACKED | OPEN_FRM_ONLY |
| NULLABLE | OPEN_FRM_ONLY |
| INDEX_TYPE | OPEN_FULL_TABLE |
| COMMENT | OPEN_FRM_ONLY |

- **TABLES**:

| Column | Optimization type |
|---------------|-------------------|
| TABLE_CATALOG | SKIP_OPEN_TABLE |
| TABLE_SCHEMA | SKIP_OPEN_TABLE |
| TABLE_NAME | SKIP_OPEN_TABLE |
| TABLE_TYPE | OPEN_FRM_ONLY |
| ENGINE | OPEN_FRM_ONLY |
| VERSION | OPEN_FRM_ONLY |
| ROW_FORMAT | OPEN_FULL_TABLE |
| TABLE_ROWS | OPEN_FULL_TABLE |

| Column | Optimization type |
|-----------------|-------------------|
| AVG_ROW_LENGTH | OPEN_FULL_TABLE |
| DATA_LENGTH | OPEN_FULL_TABLE |
| MAX_DATA_LENGTH | OPEN_FULL_TABLE |
| INDEX_LENGTH | OPEN_FULL_TABLE |
| DATA_FREE | OPEN_FULL_TABLE |
| AUTO_INCREMENT | OPEN_FULL_TABLE |
| CREATE_TIME | OPEN_FULL_TABLE |
| UPDATE_TIME | OPEN_FULL_TABLE |
| CHECK_TIME | OPEN_FULL_TABLE |
| TABLE_COLLATION | OPEN_FRM_ONLY |
| CHECKSUM | OPEN_FULL_TABLE |
| CREATE_OPTIONS | OPEN_FRM_ONLY |
| TABLE_COMMENT | OPEN_FRM_ONLY |

- TABLE_CONSTRAINTS: OPEN_FULL_TABLE applies to all columns
- TRIGGERS: OPEN_TRIGGER_ONLY applies to all columns
- VIEWS:

| Column | Optimization type |
|----------------------|-------------------|
| TABLE_CATALOG | OPEN_FRM_ONLY |
| TABLE_SCHEMA | OPEN_FRM_ONLY |
| TABLE_NAME | OPEN_FRM_ONLY |
| VIEW_DEFINITION | OPEN_FRM_ONLY |
| CHECK_OPTION | OPEN_FRM_ONLY |
| IS_UPDATABLE | OPEN_FULL_TABLE |
| DEFINER | OPEN_FRM_ONLY |
| SECURITY_TYPE | OPEN_FRM_ONLY |
| CHARACTER_SET_CLIENT | OPEN_FRM_ONLY |
| COLLATION_CONNECTION | OPEN_FRM_ONLY |

3) Use **EXPLAIN** to determine whether the server can use **INFORMATION_SCHEMA** optimizations for a query

This applies particularly for **INFORMATION_SCHEMA** queries that search for information from more than one database, which might take a long time and impact performance. The **Extra** value in **EXPLAIN** output indicates which, if any, of the optimizations described earlier the server can use to evaluate **INFORMATION_SCHEMA** queries. The following examples demonstrate the kinds of information you can expect to see in the **Extra** value.

```
mysql> EXPLAIN SELECT TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS WHERE
      TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v1'\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: VIEWS
      type: ALL
possible_keys: NULL
      key: TABLE_SCHEMA, TABLE_NAME
      key_len: NULL
```

```

        ref: NULL
        rows: NULL
        Extra: Using where; Open_frm_only; Scanned 0 databases
    
```

Use of constant database and table lookup values enables the server to avoid directory scans. For references to `VIEWS.TABLE_NAME`, only the `.frm` file need be opened.

```

mysql> EXPLAIN SELECT TABLE_NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.TABLES\G
***** 1. row *****
        id: 1
        select_type: SIMPLE
        table: TABLES
        type: ALL
possible_keys: NULL
        key: NULL
        key_len: NULL
        ref: NULL
        rows: NULL
        Extra: Open_full_table; Scanned all databases
    
```

No lookup values are provided (there is no `WHERE` clause), so the server must scan the data directory and each database directory. For each table thus identified, the table name and row format are selected. `TABLE_NAME` requires no further table files to be opened (the `SKIP_OPEN_TABLE` optimization applies). `ROW_FORMAT` requires all table files to be opened (`OPEN_FULL_TABLE` applies). `EXPLAIN` reports `OPEN_FULL_TABLE` because it is more expensive than `SKIP_OPEN_TABLE`.

```

mysql> EXPLAIN SELECT TABLE_NAME, TABLE_TYPE FROM INFORMATION_SCHEMA.TABLES
        WHERE TABLE_SCHEMA = 'test'\G
***** 1. row *****
        id: 1
        select_type: SIMPLE
        table: TABLES
        type: ALL
possible_keys: NULL
        key: TABLE_SCHEMA
        key_len: NULL
        ref: NULL
        rows: NULL
        Extra: Using where; Open_frm_only; Scanned 1 database
    
```

No table name lookup value is provided, so the server must scan the `test` database directory. For the `TABLE_NAME` and `TABLE_TYPE` columns, the `SKIP_OPEN_TABLE` and `OPEN_FRM_ONLY` optimizations apply, respectively. `EXPLAIN` reports `OPEN_FRM_ONLY` because it is more expensive.

```

mysql> EXPLAIN SELECT B.TABLE_NAME
        FROM INFORMATION_SCHEMA.TABLES AS A, INFORMATION_SCHEMA.COLUMNS AS B
        WHERE A.TABLE_SCHEMA = 'test'
        AND A.TABLE_NAME = 't1'
        AND B.TABLE_NAME = A.TABLE_NAME\G
***** 1. row *****
        id: 1
        select_type: SIMPLE
        table: A
        type: ALL
possible_keys: NULL
        key: TABLE_SCHEMA, TABLE_NAME
        key_len: NULL
        ref: NULL
        rows: NULL
        Extra: Using where; Skip_open_table; Scanned 0 databases
***** 2. row *****
        id: 1
        select_type: SIMPLE
        table: B
        type: ALL
possible_keys: NULL
        key: NULL
        key_len: NULL
        ref: NULL
        rows: NULL
    
```

```
Extra: Using where; Open_frm_only; Scanned all databases;
      Using join buffer
```

For the first `EXPLAIN` output row: Constant database and table lookup values enable the server to avoid directory scans for `TABLES` values. References to `TABLES.TABLE_NAME` require no further table files.

For the second `EXPLAIN` output row: All `COLUMNS` table values are `OPEN_FRM_ONLY` lookups, so `COLUMNS.TABLE_NAME` requires the `.frm` file to be opened.

```
mysql> EXPLAIN SELECT * FROM INFORMATION_SCHEMA.COLLATIONS\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: COLLATIONS
      type: ALL
possible_keys: NULL
      key: NULL
      key_len: NULL
      ref: NULL
      rows: NULL
      Extra:
```

In this case, no optimizations apply because `COLLATIONS` is not one of the `INFORMATION_SCHEMA` tables for which optimizations are available.

8.2.4 Optimizing Data Change Statements

This section explains how to speed up data change statements: `INSERT`, `UPDATE`, and `DELETE`. Traditional OLTP applications and modern web applications typically do many small data change operations, where concurrency is vital. Data analysis and reporting applications typically run data change operations that affect many rows at once, where the main considerations is the I/O to write large amounts of data and keep indexes up-to-date. For inserting and updating large volumes of data (known in the industry as ETL, for “extract-transform-load”), sometimes you use other SQL statements or external commands, that mimic the effects of `INSERT`, `UPDATE`, and `DELETE` statements.

8.2.4.1 Optimizing INSERT Statements

To optimize insert speed, combine many small operations into a single large operation. Ideally, you make a single connection, send the data for many new rows at once, and delay all index updates and consistency checking until the very end.

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 × size of row)
- Inserting indexes: (1 × number of indexes)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by $\log N$, assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use `INSERT` statements with multiple `VALUES` lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row `INSERT` statements. If you are adding data to a nonempty table, you can tune the `bulk_insert_buffer_size` variable to make data insertion even faster. See [Section 5.1.7, “Server System Variables”](#).
- When loading a table from a text file, use `LOAD DATA`. This is usually 20 times faster than using `INSERT` statements. See [Section 13.2.6, “LOAD DATA Statement”](#).
- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.
- See [Section 8.5.4, “Bulk Data Loading for InnoDB Tables”](#) for tips specific to `InnoDB` tables.
- See [Section 8.6.2, “Bulk Data Loading for MyISAM Tables”](#) for tips specific to `MyISAM` tables.

8.2.4.2 Optimizing UPDATE Statements

An update statement is optimized like a `SELECT` query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a `MyISAM` table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use `OPTIMIZE TABLE` occasionally. See [Section 13.7.2.4, “OPTIMIZE TABLE Statement”](#).

8.2.4.3 Optimizing DELETE Statements

The time required to delete individual rows in a `MyISAM` table is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the `key_buffer_size` system variable. See [Section 5.1.1, “Configuring the Server”](#).

To delete all rows from a `MyISAM` table, `TRUNCATE TABLE tbl_name` is faster than `DELETE FROM tbl_name`. Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See [Section 13.1.33, “TRUNCATE TABLE Statement”](#).

8.2.5 Optimizing Database Privileges

The more complex your privilege setup, the more overhead applies to all SQL statements. Simplifying the privileges established by `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, consider using a simplified grant structure to reduce permission-checking overhead.

8.2.6 Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- If your application makes several database requests to perform related updates, combining the statements into a stored routine can help performance. Similarly, if your application computes a single result based on several column values or large volumes of data, combining the computation into a UDF (user-defined function) can help performance. The resulting fast database operations are then available to be reused by other queries, applications, and even code written in different

programming languages. See [Section 20.2, “Using Stored Routines”](#) and [Section 24.4, “Adding Functions to MySQL”](#) for more information.

- To fix any compression issues that occur with `ARCHIVE` tables, use `OPTIMIZE TABLE`. See [Section 15.6, “The ARCHIVE Storage Engine”](#).
- If possible, classify reports as “live” or as “statistical”, where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.
- If you have data that does not conform well to a rows-and-columns table structure, you can pack and store data into a `BLOB` column. In this case, you must provide code in your application to pack and unpack information, but this might save I/O operations to read and write the sets of related values.
- With Web servers, store images and other binary assets as files, with the path name stored in the database rather than the file itself. Most Web servers are better at caching files than database contents, so using files is generally faster. (Although you must handle backups and storage issues yourself in this case.)
- If you need really high speed, look at the low-level MySQL interfaces. For example, by accessing the MySQL `InnoDB` or `MyISAM` storage engine directly, you could get a substantial speed increase compared to using the SQL interface.
- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replication servers to split up the load. To avoid slowing down the master while making backups, you can make backups using a slave server. See [Chapter 17, *Replication*](#).

8.3 Optimization and Indexes

The best way to improve the performance of `SELECT` operations is to create indexes on one or more of the columns that are tested in the query. The index entries act like pointers to the table rows, allowing the query to quickly determine which rows match a condition in the `WHERE` clause, and retrieve the other column values for those rows. All MySQL data types can be indexed.

Although it can be tempting to create an indexes for every possible column used in a query, unnecessary indexes waste space and waste time for MySQL to determine which indexes to use. Indexes also add to the cost of inserts, updates, and deletes because each index must be updated. You must find the right balance to achieve fast queries using the optimal set of indexes.

8.3.1 How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. This is much faster than reading every row sequentially.

Most MySQL indexes (`PRIMARY KEY`, `UNIQUE`, `INDEX`, and `FULLTEXT`) are stored in B-trees. Exceptions are that indexes on spatial data types use R-trees, and that `MEMORY` tables also support hash indexes.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in `MEMORY` tables) are described in [Section 8.3.8, “Comparison of B-Tree and Hash Indexes”](#).

MySQL uses indexes for these operations:

- To find the rows matching a `WHERE` clause quickly.
- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows (the most `selective` index).

- If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on (`col1`, `col2`, `col3`), you have indexed search capabilities on (`col1`), (`col1`, `col2`), and (`col1`, `col2`, `col3`). For more information, see [Section 8.3.5, “Multiple-Column Indexes”](#).
- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. For example, `VARCHAR(10)` and `CHAR(10)` are the same size, but `VARCHAR(10)` and `CHAR(15)` are not.

For comparisons between nonbinary string columns, both columns should use the same character set. For example, comparing a `utf8` column with a `latin1` column precludes use of an index.

Comparison of dissimilar columns (comparing a string column to a temporal or numeric column, for example) may prevent use of indexes if values cannot be compared directly without conversion. For a given value such as `1` in the numeric column, it might compare equal to any number of values in the string column such as `'1'`, `' 1'`, `'00001'`, or `'01.e1'`. This rules out use of any indexes for the string column.

- To find the `MIN()` or `MAX()` value for a specific indexed column `key_col`. This is optimized by a preprocessor that checks whether you are using `WHERE key_part_N = constant` on all key parts that occur before `key_col` in the index. In this case, MySQL does a single key lookup for each `MIN()` or `MAX()` expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```
SELECT MIN(key_part2),MAX(key_part2)
FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable index (for example, `ORDER BY key_part1, key_part2`). If all key parts are followed by `DESC`, the key is read in reverse order. See [Section 8.2.1.10, “ORDER BY Optimization”](#), and [Section 8.2.1.11, “GROUP BY Optimization”](#).
- In some cases, a query can be optimized to retrieve values without consulting the data rows. (An index that provides all the necessary results for a query is called a [covering index](#).) If a query uses from a table only columns that are included in some index, the selected values can be retrieved from the index tree for greater speed:

```
SELECT key_part3 FROM tbl_name
WHERE key_part1=1
```

Indexes are less important for queries on small tables, or big tables where report queries process most or all of the rows. When a query needs to access most of the rows, reading sequentially is faster than working through an index. Sequential reads minimize disk seeks, even if not all the rows are needed for the query. See [Section 8.2.1.16, “Avoiding Full Table Scans”](#) for details.

8.3.2 Primary Key Optimization

The primary key for a table represents the column or set of columns that you use in your most vital queries. It has an associated index, for fast query performance. Query performance benefits from the `NOT NULL` optimization, because it cannot include any `NULL` values. With the `InnoDB` storage engine, the table data is physically organized to do ultra-fast lookups and sorts based on the primary key column or columns.

If your table is big and important, but does not have an obvious column or set of columns to use as a primary key, you might create a separate column with auto-increment values to use as the primary key. These unique IDs can serve as pointers to corresponding rows in other tables when you join tables using foreign keys.

8.3.3 Foreign Key Optimization

If a table has many columns, and you query many different combinations of columns, it might be efficient to split the less-frequently used data into separate tables with a few columns each, and relate them back to the main table by duplicating the numeric ID column from the main table. That way, each small table can have a primary key for fast lookups of its data, and you can query just the set of columns that you need using a join operation. Depending on how the data is distributed, the queries might perform less I/O and take up less cache memory because the relevant columns are packed together on disk. (To maximize performance, queries try to read as few data blocks as possible from disk; tables with only a few columns can fit more rows in each data block.)

8.3.4 Column Indexes

The most common type of index involves a single column, storing copies of the values from that column in a data structure, allowing fast lookups for the rows with the corresponding column values. The B-tree data structure lets the index quickly find a specific value, a set of values, or a range of values, corresponding to operators such as =, >, ≤, BETWEEN, IN, and so on, in a WHERE clause.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See [Chapter 14, The InnoDB Storage Engine](#), and [Chapter 15, Alternative Storage Engines](#). All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

For additional information about column indexes, see [Section 13.1.13, “CREATE INDEX Statement”](#).

- [Index Prefixes](#)
- [FULLTEXT Indexes](#)
- [Spatial Indexes](#)
- [Indexes in the MEMORY Storage Engine](#)

Index Prefixes

With `col_name(N)` syntax in an index specification for a string column, you can create an index that uses only the first *N* characters of the column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a BLOB or TEXT column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for InnoDB tables, unless you have `innodb_large_prefix` set).

Note

Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

If a search term exceeds the index prefix length, the index is used to exclude non-matching rows, and the remaining rows are examined for possible matches.

For additional information about index prefixes, see [Section 13.1.13, “CREATE INDEX Statement”](#).

FULLTEXT Indexes

FULLTEXT indexes are used for full-text searches. Only the MyISAM storage engine supports FULLTEXT indexes and only for CHAR, VARCHAR, and TEXT columns. Indexing always takes place over

the entire column and column prefix indexing is not supported. For details, see [Section 12.9, “Full-Text Search Functions”](#).

For queries that contain full-text expressions, MySQL evaluates those expressions during the optimization phase of query execution. The optimizer does not just look at full-text expressions and make estimates, it actually evaluates them in the process of developing an execution plan.

An implication of this behavior is that `EXPLAIN` for full-text queries is typically slower than for non-full-text queries for which no expression evaluation occurs during the optimization phase.

`EXPLAIN` for full-text queries may show `Select tables optimized away` in the `Extra` column due to matching occurring during optimization; in this case, no table access need occur during later execution.

Spatial Indexes

You can create indexes on spatial data types. Only `MyISAM` supports R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for `ARCHIVE`, which does not support spatial type indexing).

Indexes in the MEMORY Storage Engine

The `MEMORY` storage engine uses `HASH` indexes by default, but also supports `BTREE` indexes.

8.3.5 Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see [Section 8.3.4, “Column Indexes”](#)).

MySQL can use multiple-column indexes for queries that test all the columns in the index, or queries that test just the first column, the first two columns, the first three columns, and so on. If you specify the columns in the right order in the index definition, a single composite index can speed up several kinds of queries on the same table.

A multiple-column index can be considered a sorted array, the rows of which contain values that are created by concatenating the values of the indexed columns.

Note

As an alternative to a composite index, you can introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it might be faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```
SELECT * FROM tbl_name
WHERE hash_col=MD5(CONCAT(val1,val2))
AND col1=val1 AND col2=val2;
```

Suppose that a table has the following specification:

```
CREATE TABLE test (
  id          INT NOT NULL,
  last_name   CHAR(30) NOT NULL,
  first_name  CHAR(30) NOT NULL,
  PRIMARY KEY (id),
  INDEX name (last_name,first_name)
);
```

The `name` index is an index over the `last_name` and `first_name` columns. The index can be used for lookups in queries that specify values in a known range for combinations of `last_name` and `first_name` values. It can also be used for queries that specify just a `last_name` value because that column is a leftmost prefix of the index (as described later in this section). Therefore, the `name` index is used for lookups in the following queries:

```
SELECT * FROM test WHERE last_name='Smith';

SELECT * FROM test
  WHERE last_name='Smith' AND first_name='John';

SELECT * FROM test
  WHERE last_name='Smith'
    AND (first_name='John' OR first_name='Jon');

SELECT * FROM test
  WHERE last_name='Smith'
    AND first_name >='M' AND first_name < 'N';
```

However, the `name` index is *not* used for lookups in the following queries:

```
SELECT * FROM test WHERE first_name='John';

SELECT * FROM test
  WHERE last_name='Smith' OR first_name='John';
```

Suppose that you issue the following `SELECT` statement:

```
SELECT * FROM tbl_name
  WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer attempts to use the Index Merge optimization (see [Section 8.2.1.3, “Index Merge Optimization”](#)), or attempts to find the most restrictive index by deciding which index excludes more rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`.

MySQL cannot use the index to perform lookups if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;

SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on `(col1, col2, col3)`, only the first two queries use the index. The third and fourth queries do involve indexed columns, but do not use an index to perform lookups because `(col2)` and `(col2, col3)` are not leftmost prefixes of `(col1, col2, col3)`.

8.3.6 Verifying Index Usage

Always check whether all your queries really use the indexes that you have created in the tables. Use the `EXPLAIN` statement, as described in [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#).

8.3.7 InnoDB and MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how many rows must be read for each `ref` access
- To estimate how many rows a partial join will produce; that is, the number of rows that an operation of this form will produce:

```
(...) JOIN tbl_name ON tbl_name.key = expr
```

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The `SHOW INDEX` statement displays a cardinality value based on N/S , where N is the number of rows in the table and S is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the `<=>` comparison operator, `NULL` is not treated differently from any other value: `NULL <=> NULL`, just as `N <=> N` for any other N .

However, for a join based on the `=` operator, `NULL` is different from non-`NULL` values: `expr1 = expr2` is not true when `expr1` or `expr2` (or both) are `NULL`. This affects `ref` accesses for comparisons of the form `tbl_name.key = expr`: MySQL will not access the table if the current value of `expr` is `NULL`, because the comparison cannot be true.

For `=` comparisons, it does not matter how many `NULL` values are in the table. For optimization purposes, the relevant value is the average size of the non-`NULL` value groups. However, MySQL does not currently enable that average size to be collected or used.

For `InnoDB` and `MyISAM` tables, you have some control over collection of table statistics by means of the `innodb_stats_method` and `myisam_stats_method` system variables, respectively. These variables have three possible values, which differ as follows:

- When the variable is set to `nulls_equal`, all `NULL` values are treated as identical (that is, they all form a single value group).

If the `NULL` value group size is much higher than the average non-`NULL` value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-`NULL` values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for `ref` accesses when it should.

- When the variable is set to `nulls_unequal`, `NULL` values are not considered the same. Instead, each `NULL` value forms a separate value group of size 1.

If you have many `NULL` values, this method skews the average value group size downward. If the average non-`NULL` value group size is large, counting `NULL` values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-`NULL` values. Consequently, the `nulls_unequal` method may cause the optimizer to use this index for `ref` lookups when other methods may be better.

- When the variable is set to `nulls_ignored`, `NULL` values are ignored.

If you tend to use many joins that use `<=>` rather than `=`, `NULL` values are not special in comparisons and one `NULL` is equal to another. In this case, `nulls_equal` is the appropriate statistics method.

The `innodb_stats_method` system variable has a global value; the `myisam_stats_method` system variable has both global and session values. Setting the global value affects statistics collection for tables from the corresponding storage engine. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table's statistics to be regenerated with a given method without affecting other clients by setting the session value of `myisam_stats_method`.

To regenerate `MyISAM` table statistics, you can use any of the following methods:

- Execute `myisamchk --stats_method=method_name --analyze`
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set `myisam_stats_method` and issue an `ANALYZE TABLE` statement

Some caveats regarding the use of `innodb_stats_method` and `myisam_stats_method`:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some `ALTER TABLE` statements, for example.) If this happens, the statistics are collected using whatever value `innodb_stats_method` or `myisam_stats_method` has at the time. Thus, if you collect statistics using one method, but the system variable is set to the other method when a table's statistics are collected automatically later, the other method will be used.
- There is no way to tell which method was used to generate statistics for a given table.
- These variables apply only to `InnoDB` and `MyISAM` tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the `nulls_equal` method.

8.3.8 Comparison of B-Tree and Hash Indexes

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the `MEMORY` storage engine that lets you choose B-tree or hash indexes.

- [B-Tree Index Characteristics](#)
- [Hash Index Characteristics](#)

B-Tree Index Characteristics

A B-tree index can be used for column comparisons in expressions that use the `=`, `>`, `>=`, `<`, `<=`, or `BETWEEN` operators. The index also can be used for `LIKE` comparisons if the argument to `LIKE` is a constant string that does not start with a wildcard character. For example, the following `SELECT` statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%ck%';
```

In the first statement, only rows with `'Patrick' <= key_col < 'Patricl'` are considered. In the second statement, only rows with `'Pat' <= key_col < 'Pau'` are considered.

The following `SELECT` statements do not use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the `LIKE` value begins with a wildcard character. In the second statement, the `LIKE` value is not a constant.

If you use `... LIKE '%string%'` and `string` is longer than three characters, MySQL uses the *Turbo Boyer-Moore algorithm* to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using `col_name IS NULL` employs indexes if `col_name` is indexed.

Any index that does not span all `AND` levels in the `WHERE` clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every `AND` group.

The following `WHERE` clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3

/* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2

/* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5
```

```
/* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These `WHERE` clauses do *not* use indexes:

```
/* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2

/* Index is not used in both parts of the WHERE clause */
... WHERE index=1 OR A=10

/* No index spans all rows */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses `LIMIT` to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

Hash Index Characteristics

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the `=` or `<=>` operators (but are *very* fast). They are not used for comparison operators such as `<` that find a range of values. Systems that rely on this type of single-value lookup are known as “key-value stores”; to use MySQL for such applications, use hash indexes wherever possible.
- The optimizer cannot use a hash index to speed up `ORDER BY` operations. (This type of index cannot be used to search for the next entry in order.)
- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a `MyISAM` or `InnoDB` table to a hash-indexed `MEMORY` table.
- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

8.3.9 Indexed Lookups from `TIMESTAMP` Columns

Temporal values are stored in `TIMESTAMP` columns as UTC values, and values inserted into and retrieved from `TIMESTAMP` columns are converted between the session time zone and UTC. (This is the same type of conversion performed by the `CONVERT_TZ()` function. If the session time zone is UTC, there is effectively no time zone conversion.)

Due to conventions for local time zone changes such as Daylight Saving Time (DST), conversions between UTC and non-UTC time zones are not one-to-one in both directions. UTC values that are distinct may not be distinct in another time zone. The following example shows distinct UTC values that become identical in a non-UTC time zone:

```
mysql> CREATE TABLE tstable (ts TIMESTAMP);
mysql> SET time_zone = 'UTC'; -- insert UTC values
mysql> INSERT INTO tstable VALUES
      ('2018-10-28 00:30:00'),
      ('2018-10-28 01:30:00');
mysql> SELECT ts FROM tstable;
+-----+
| ts          |
+-----+
| 2018-10-28 00:30:00 |
| 2018-10-28 01:30:00 |
+-----+
mysql> SET time_zone = 'MET'; -- retrieve non-UTC values
```

```
mysql> SELECT ts FROM tstable;
+-----+
| ts    |
+-----+
| 2018-10-28 02:30:00 |
| 2018-10-28 02:30:00 |
+-----+
```

**Note**

To use named time zones such as `'MET'` or `'Europe/Amsterdam'`, the time zone tables must be properly set up. For instructions, see [Section 5.1.12, “MySQL Server Time Zone Support”](#).

You can see that the two distinct UTC values are the same when converted to the `'MET'` time zone. This phenomenon can lead to different results for a given `TIMESTAMP` column query, depending on whether the optimizer uses an index to execute the query.

Suppose that a query selects values from the table shown earlier using a `WHERE` clause to search the `ts` column for a single specific value such as a user-provided timestamp literal:

```
SELECT ts FROM tstable
WHERE ts = 'literal';
```

Suppose further that the query executes under these conditions:

- The session time zone is not UTC and has a DST shift. For example:

```
SET time_zone = 'MET';
```

- Unique UTC values stored in the `TIMESTAMP` column are not unique in the session time zone due to DST shifts. (The example shown earlier illustrates how this can occur.)
- The query specifies a search value that is within the hour of entry into DST in the session time zone.

Under those conditions, the comparison in the `WHERE` clause occurs in different ways for nonindexed and indexed lookups and leads to different results:

- If there is no index or the optimizer cannot use it, comparisons occur in the session time zone. The optimizer performs a table scan in which it retrieves each `ts` column value, converts it from UTC to the session time zone, and compares it to the search value (also interpreted in the session time zone):

```
mysql> SELECT ts FROM tstable
        WHERE ts = '2018-10-28 02:30:00';
+-----+
| ts    |
+-----+
| 2018-10-28 02:30:00 |
| 2018-10-28 02:30:00 |
+-----+
```

Because the stored `ts` values are converted to the session time zone, it is possible for the query to return two timestamp values that are distinct as UTC values but equal in the session time zone: One value that occurs before the DST shift when clocks are changed, and one value that occurs after the DST shift.

- If there is a usable index, comparisons occur in UTC. The optimizer performs an index scan, first converting the search value from the session time zone to UTC, then comparing the result to the UTC index entries:

```
mysql> ALTER TABLE tstable ADD INDEX (ts);
mysql> SELECT ts FROM tstable
        WHERE ts = '2018-10-28 02:30:00';
+-----+
| ts    |
```

```
+-----+
| 2018-10-28 02:30:00 |
+-----+
```

In this case, the (converted) search value is matched only to index entries, and because the index entries for the distinct stored UTC values are also distinct, the search value can match only one of them.

Due to different optimizer operation for nonindexed and indexed lookups, the query produces different results in each case. The result from the nonindexed lookup returns all values that match in the session time zone. The indexed lookup cannot do so:

- It is performed within the storage engine, which knows only about UTC values.
- For the two distinct session time zone values that map to the same UTC value, the indexed lookup matches only the corresponding UTC index entry and returns only a single row.

In the preceding discussion, the data set stored in `tstable` happens to consist of distinct UTC values. In such cases, all index-using queries of the form shown match at most one index entry.

If the index is not `UNIQUE`, it is possible for the table (and the index) to store multiple instances of a given UTC value. For example, the `ts` column might contain multiple instances of the UTC value `'2018-10-28 00:30:00'`. In this case, the index-using query would return each of them (converted to the MET value `'2018-10-28 02:30:00'` in the result set). It remains true that index-using queries match the converted search value to a single value in the UTC index entries, rather than matching multiple UTC values that convert to the search value in the session time zone.

If it is important to return all `ts` values that match in the session time zone, the workaround is to suppress use of the index with an `IGNORE INDEX` hint:

```
mysql> SELECT ts FROM tstable
      IGNORE INDEX (ts)
      WHERE ts = '2018-10-28 02:30:00';
+-----+
| ts          |
+-----+
| 2018-10-28 02:30:00 |
| 2018-10-28 02:30:00 |
+-----+
```

The same lack of one-to-one mapping for time zone conversions in both directions occurs in other contexts as well, such as conversions performed with the `FROM_UNIXTIME()` and `UNIX_TIMESTAMP()` functions. See [Section 12.6, “Date and Time Functions”](#).

8.4 Optimizing Database Structure

In your role as a database designer, look for the most efficient way to organize your schemas, tables, and columns. As when tuning application code, you minimize I/O, keep related items together, and plan ahead so that performance stays high as the data volume increases. Starting with an efficient database design makes it easier for team members to write high-performing application code, and makes the database likely to endure as applications evolve and are rewritten.

8.4.1 Optimizing Data Size

Design your tables to minimize their space on the disk. This can result in huge improvements by reducing the amount of data written to and read from disk. Smaller tables normally require less main memory while their contents are being actively processed during query execution. Any space reduction for table data also results in smaller indexes that can be processed faster.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application can give you a big performance gain. See [Chapter 14, *The InnoDB Storage Engine*](#), and [Chapter 15, *Alternative Storage Engines*](#).

You can get better performance for a table and minimize storage space by using the techniques listed here:

- [Table Columns](#)
- [Row Format](#)
- [Indexes](#)
- [Joins](#)
- [Normalization](#)

Table Columns

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. `MEDIUMINT` is often a better choice than `INT` because a `MEDIUMINT` column uses 25% less space.
- Declare columns to be `NOT NULL` if possible. It makes SQL operations faster, by enabling better use of indexes and eliminating overhead for testing whether each value is `NULL`. You also save some storage space, one bit per column. If you really need `NULL` values in your tables, use them. Just avoid the default setting that allows `NULL` values in every column.

Row Format

- In MySQL 5.5, `InnoDB` tables use the `COMPACT` row storage format (`ROW_FORMAT=COMPACT`) by default. Older versions of MySQL use the `REDUNDANT` row format (`ROW_FORMAT=REDUNDANT`).

The compact family of row formats, which includes `COMPACT`, `DYNAMIC`, and `COMPRESSED`, decreases row storage space at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

The compact family of row formats also optimizes `CHAR` column storage when using a variable-length character set such as `utf8mb3` or `utf8mb4`. With `ROW_FORMAT=REDUNDANT`, `CHAR(N)` occupies $N \times$ the maximum byte length of the character set. Many languages can be written primarily using single-byte `utf8` characters, so a fixed storage length often wastes space. With the compact family of rows formats, `InnoDB` allocates a variable amount of storage in the range of N to $N \times$ the maximum byte length of the character set for these columns by stripping trailing spaces. The minimum storage length is N bytes to facilitate in-place updates in typical cases. For more information, see [Section 14.14, “InnoDB Row Formats”](#).

- To minimize space even further by storing table data in compressed form, specify `ROW_FORMAT=COMPRESSED` when creating `InnoDB` tables, or run the `mysampack` command on an existing `MyISAM` table. (`InnoDB` compressed tables are readable and writable, while `MyISAM` compressed tables are read-only.)
- For `MyISAM` tables, if you do not have any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB` columns), a fixed-size row format is used. This is faster but may waste some space. See [Section 15.3.3, “MyISAM Table Storage Formats”](#). You can hint that you want to have fixed length rows even if you have `VARCHAR` columns with the `CREATE TABLE` option `ROW_FORMAT=FIXED`.

Indexes

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient. For `InnoDB` tables, the primary key columns are duplicated in each secondary index entry, so a short primary key saves considerable space if you have many secondary indexes.
- Create only the indexes that you need to improve query performance. Indexes are good for retrieval, but slow down insert and update operations. If you access a table mostly by searching on a

combination of columns, create a single composite index on them rather than a separate index for each column. The first part of the index should be the column most used. If you *always* use many columns when selecting from the table, the first column in the index should be the one with the most duplicates, to obtain better compression of the index.

- If it is very likely that a long string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see [Section 13.1.13, "CREATE INDEX Statement"](#)). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See [Section 5.1.1, "Configuring the Server"](#).

Joins

- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.
- Declare columns with identical information in different tables with identical data types, to speed up joins based on the corresponding columns.
- Keep column names simple, so that you can use the same name across different tables and simplify join queries. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, consider keeping them shorter than 18 characters.

Normalization

- Normally, try to keep all data nonredundant (observing what is referred to in database theory as *third normal form*). Instead of repeating lengthy values such as names and addresses, assign them unique IDs, repeat these IDs as needed across multiple smaller tables, and join the tables in queries by referencing the IDs in the join clause.
- If speed is more important than disk space and the maintenance costs of keeping multiple copies of data, for example in a business intelligence scenario where you analyze all the data from large tables, you can relax the normalization rules, duplicating information or creating summary tables to gain more speed.

8.4.2 Optimizing MySQL Data Types

8.4.2.1 Optimizing for Numeric Data

- For unique IDs or other values that can be represented as either strings or numbers, prefer numeric columns to string columns. Since large numeric values can be stored in fewer bytes than the corresponding strings, it is faster and takes less memory to transfer and compare them.
- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you can avoid parsing the text file to find line and column boundaries.

8.4.2.2 Optimizing for Character and String Types

For character and string columns, follow these guidelines:

- Use binary collation order for fast comparison and sort operations, when you do not need language-specific collation features. You can use the `BINARY` operator to use binary collation within a particular query.
- When comparing values from different columns, declare those columns with the same character set and collation wherever possible, to avoid string conversions while running the query.

- For column values less than 8KB in size, use binary `VARCHAR` instead of `BLOB`. The `GROUP BY` and `ORDER BY` clauses can generate temporary tables, and these temporary tables can use the `MEMORY` storage engine if the original table does not contain any `BLOB` columns.
- If a table contains string columns such as name and address, but many queries do not retrieve those columns, consider splitting the string columns into a separate table and using join queries with a foreign key when necessary. When MySQL retrieves any value from a row, it reads a data block containing all the columns of that row (and possibly other adjacent rows). Keeping each row small, with only the most frequently used columns, allows more rows to fit in each data block. Such compact tables reduce disk I/O and memory usage for common queries.
- When you use a randomly generated value as a primary key in an `InnoDB` table, prefix it with an ascending value such as the current date and time if possible. When consecutive primary values are physically stored near each other, `InnoDB` can insert and retrieve them faster.
- See [Section 8.4.2.1, “Optimizing for Numeric Data”](#) for reasons why a numeric column is usually preferable to an equivalent string column.

8.4.2.3 Optimizing for BLOB Types

- When storing a large blob containing textual data, consider compressing it first. Do not use this technique when the entire table is compressed by `InnoDB` or `MyISAM`.
- For a table with several columns, to reduce memory requirements for queries that do not use the `BLOB` column, consider splitting the `BLOB` column into a separate table and referencing it with a join query when needed.
- Since the performance requirements to retrieve and display a `BLOB` value might be very different from other data types, you could put the `BLOB`-specific table on a different storage device or even a separate database instance. For example, to retrieve a `BLOB` might require a large sequential disk read that is better suited to a traditional hard drive than to an [SSD device](#).
- See [Section 8.4.2.2, “Optimizing for Character and String Types”](#) for reasons why a binary `VARCHAR` column is sometimes preferable to an equivalent `BLOB` column.
- Rather than testing for equality against a very long text string, you can store a hash of the column value in a separate column, index that column, and test the hashed value in queries. (Use the `MD5()` or `CRC32()` function to produce the hash value.) Since hash functions can produce duplicate results for different inputs, you still include a clause `AND blob_column = long_string_value` in the query to guard against false matches; the performance benefit comes from the smaller, easily scanned index for the hashed values.

8.4.2.4 Using PROCEDURE ANALYSE

```
ANALYSE([max_elements[,max_memory]])
```

`ANALYSE()` examines the result from a query and returns an analysis of the results that suggests optimal data types for each column that may help reduce table sizes. To obtain this analysis, append `PROCEDURE ANALYSE` to the end of a `SELECT` statement:

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])
```

For example:

```
SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);
```

The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that `PROCEDURE ANALYSE()` does not suggest the `ENUM` data type when it is not appropriate.

The arguments are optional and are used as follows:

- `max_elements` (default 256) is the maximum number of distinct values that `ANALYSE()` notices per column. This is used by `ANALYSE()` to check whether the optimal data type should be of type `ENUM`; if there are more than `max_elements` distinct values, then `ENUM` is not a suggested type.
- `max_memory` (default 8192) is the maximum amount of memory that `ANALYSE()` should allocate per column while trying to find all distinct values.

A `PROCEDURE` clause is not permitted in a `UNION` statement.

8.4.3 Optimizing for Many Tables

Some techniques for keeping individual queries fast involve splitting data across many tables. When the number of tables runs into the thousands or even millions, the overhead of dealing with all these tables becomes a new performance consideration.

8.4.3.1 How MySQL Opens and Closes Tables

When you execute a `mysqladmin status` command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have fewer than 12 tables.

MySQL is multithreaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With `MyISAM` tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The `table_open_cache` and `max_connections` system variables affect the maximum number of files the server keeps open. If you increase one or both of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

`table_open_cache` is related to `max_connections`. For example, for 200 concurrent running connections, specify a table cache size of at least $200 * N$, where N is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_open_cache` setting. If `table_open_cache` is set too high, MySQL may run out of file descriptors and exhibit symptoms such as refusing connections or failing to perform queries.

Also take into account that the `MyISAM` storage engine needs two file descriptors for each unique open table. For a partitioned `MyISAM` table, two file descriptors are required for each partition of the opened table. (When `MyISAM` opens a partitioned table, it opens every partition of this table, whether or not a given partition is actually used. See [MyISAM and partition file descriptor usage](#).) To increase the number of file descriptors available to MySQL, set the `open_files_limit` system variable. See [Section B.4.2.18, "File Not Found and Similar Errors"](#).

The cache of open tables is kept at a level of `table_open_cache` entries. The default value is 400. To set the size explicitly, set the `table_open_cache` system variable at startup. MySQL may temporarily open more tables than this to execute queries, as described later in this section.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.

- When the cache contains more than `table_open_cache` entries and a table in the cache is no longer being used by any threads.
- When a table-flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables not currently in use are released, beginning with the table least recently used.
- If a new table must be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A `MyISAM` table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any `MyISAM` table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See [Section 13.2.4, “HANDLER Statement”](#).

To determine whether your table cache is too small, check the `Opened_tables` status variable, which indicates the number of table-opening operations since the server started:

```
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Opened_tables | 2741  |
+-----+-----+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, increase the `table_open_cache` value at server startup.

8.4.3.2 Disadvantages of Creating Many Tables in the Same Database

If you have many `MyISAM` tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.

8.4.4 Internal Temporary Table Use in MySQL

In some cases, the server creates internal temporary tables while processing statements. Users have no direct control over when this occurs.

The server creates temporary tables under conditions such as these:

- Evaluation of `UNION` statements.
- Evaluation of some views, such those that use the `TEMPTABLE` algorithm, `UNION`, or aggregation.
- Evaluation of statements that contain an `ORDER BY` clause and a different `GROUP BY` clause, or for which the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue.
- Evaluation of `DISTINCT` combined with `ORDER BY` may require a temporary table.

- For queries that use the `SQL_SMALL_RESULT` modifier, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.
- To evaluate `INSERT ... SELECT` statements that select from and insert into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT`, then inserts those rows into the target table. See [Section 13.2.5.1, “INSERT ... SELECT Statement”](#).
- Evaluation of multiple-table `UPDATE` statements.
- Evaluation of `GROUP_CONCAT()` or `COUNT(DISTINCT)` expressions.

To determine whether a statement requires a temporary table, use `EXPLAIN` and check the `Extra` column to see whether it says `Using temporary` (see [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#)).

When the server creates an internal temporary table (either in memory or on disk), it increments the `Created_tmp_tables` status variable. If the server creates the table on disk (either initially or by converting an in-memory table) it increments the `Created_tmp_disk_tables` status variable.

Some query conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

- Presence of a `BLOB` or `TEXT` column in the table. This includes user-defined variables having a string value because they are treated as `BLOB` or `TEXT` columns, depending on whether their value is a binary or nonbinary string, respectively.
- Presence of any string column in a `GROUP BY` or `DISTINCT` clause larger than 512 bytes.
- Presence of any string column with a maximum length larger than 512 (bytes for binary strings, characters for nonbinary strings) in the `SELECT` list, if `UNION` or `UNION ALL` is used.
- The `SHOW COLUMNS` and `DESCRIBE` statements use `BLOB` as the type for some columns, thus the temporary table used for the results is an on-disk table.
- [Internal Temporary Table Storage Engine](#)
- [Internal Temporary Table Storage Format](#)

Internal Temporary Table Storage Engine

An internal temporary table can be held in memory and processed by the `MEMORY` storage engine, or stored on disk and processed by the `MyISAM` storage engine.

If an internal temporary table is created as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is defined by the `tmp_table_size` or `max_heap_table_size` value, whichever is smaller. This differs from `MEMORY` tables explicitly created with `CREATE TABLE`. For such tables, only the `max_heap_table_size` variable determines how large a table can grow, and there is no conversion to on-disk format.

Internal Temporary Table Storage Format

In-memory temporary tables are managed by the `MEMORY` storage engine, which uses fixed-length row format. `VARCHAR` and `VARBINARY` column values are padded to the maximum column length, in effect storing them as `CHAR` and `BINARY` columns.

On-disk temporary tables are managed by the `MyISAM` storage engine using dynamic-width row format. Columns take only as much storage as needed, which reduces disk I/O and space requirements, and processing time compared to on-disk tables that use fixed-length rows. The exception to dynamic-length row format is that on-disk temporary tables for derived tables are stored using fixed-length rows.

Prior to MySQL 5.5.47, on-disk temporary table storage uses fixed-length rows.

For statements that initially create an internal temporary table in memory, then convert it to an on-disk table, better performance might be achieved by skipping the conversion step and creating the table on disk to begin with. The `big_tables` variable can be used to force disk storage of internal temporary tables.

8.4.5 Limits on Number of Databases and Tables

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. `InnoDB` permits up to 4 billion tables.

8.4.6 Limits on Table Size

The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. For up-to-date information operating system file size limits, refer to the documentation specific to your operating system.

Windows users, please note that FAT and VFAT (FAT32) are *not* considered suitable for production use with MySQL. Use NTFS instead.

If you encounter a full-table error, there are several reasons why it might have occurred:

- The disk might be full.
- You are using `InnoDB` tables and have run out of room in an `InnoDB` tablespace file. The maximum tablespace size is four billion pages (64TB), which is also the maximum size for a table. See [Section 14.24, “InnoDB Limits”](#).

Generally, partitioning of tables into multiple tablespace files is recommended for tables larger than 1TB in size.

- You have hit an operating system file size limit. For example, you are using `MyISAM` tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.
- You are using a `MyISAM` table and the space required for the table exceeds what is permitted by the internal pointer size. `MyISAM` permits data and index files to grow up to 256TB by default, but this limit can be changed up to the maximum permissible size of 65,536TB ($256^7 - 1$ bytes).

If you need a `MyISAM` table that is larger than the default limit and your operating system supports large files, the `CREATE TABLE` statement supports `AVG_ROW_LENGTH` and `MAX_ROWS` options. See [Section 13.1.17, “CREATE TABLE Statement”](#). The server uses these options to determine how large a table to permit.

If the pointer size is too small for an existing table, you can change the options with `ALTER TABLE` to increase a table's maximum permissible size. See [Section 13.1.7, “ALTER TABLE Statement”](#).

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify `AVG_ROW_LENGTH` only for tables with `BLOB` or `TEXT` columns; in this case, MySQL cannot optimize the space required based only on the number of rows.

To change the default size limit for `MyISAM` tables, set the `myisam_data_pointer_size`, which sets the number of bytes used for internal row pointers. The value is used to set the pointer size for new tables if you do not specify the `MAX_ROWS` option. The value of `myisam_data_pointer_size` can be from 2 to 7. A value of 4 permits tables up to 4GB; a value of 6 permits tables up to 256TB.

You can check the maximum data and index sizes by using this statement:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name' ;
```

You also can use `myisamchk -dv /path/to/table-index-file`. See [Section 13.7.5, “SHOW Statements”](#), or [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

Other ways to work around file-size limits for `MyISAM` tables are as follows:

- If your large table is read only, you can use `myisampack` to compress it. `myisampack` usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. `myisampack` also can merge multiple tables into a single table. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).
- MySQL includes a `MERGE` library that enables you to handle a collection of `MyISAM` tables that have identical structure as a single `MERGE` table. See [Section 15.8, “The MERGE Storage Engine”](#).
- You are using the `NDB` storage engine, in which case you need to increase the values for the `DataMemory` and `IndexMemory` configuration parameters in your `config.ini` file. See [Section 18.3.2.1, “NDB Cluster Data Node Configuration Parameters”](#).
- You are using the `MEMORY (HEAP)` storage engine; in this case you need to increase the value of the `max_heap_table_size` system variable. See [Section 5.1.7, “Server System Variables”](#).

8.4.7 Limits on Table Column Count and Row Size

This section describes limits on the number of columns in tables and the size of individual rows.

- [Column Count Limits](#)
- [Row Size Limits](#)

Column Count Limits

MySQL has hard limit of 4096 columns per table, but the effective maximum may be less for a given table. The exact column limit depends on several factors:

- The maximum row size for a table constrains the number (and possibly size) of columns because the total length of all columns cannot exceed this size. See [Row Size Limits](#).
- The storage requirements of individual columns constrain the number of columns that fit within a given maximum row size. Storage requirements for some data types depend on factors such as storage engine, storage format, and character set. See [Section 11.6, “Data Type Storage Requirements”](#).
- Storage engines may impose additional restrictions that limit table column count. For example, `InnoDB` has a limit of 1000 columns per table. See [Section 14.24, “InnoDB Limits”](#). For information about other storage engines, see [Chapter 15, Alternative Storage Engines](#).
- Each table has an `.frm` file that contains the table definition. The definition affects the content of this file in ways that may affect the number of columns permitted in the table. See [Limits Imposed by .frm File Structure](#).

Row Size Limits

The maximum row size for a given table is determined by several factors:

- The internal representation of a MySQL table has a maximum row size limit of 65,535 bytes, even if the storage engine is capable of supporting larger rows. `BLOB` and `TEXT` columns only contribute 9 to 12 bytes toward the row size limit because their contents are stored separately from the rest of the row.

- The maximum row size for an [InnoDB](#) table, which applies to data stored locally within a database page, is slightly less than half a page. For example, the maximum row size is slightly less than 8KB for the default 16KB [InnoDB](#) page size. See [Section 14.24, “InnoDB Limits”](#).

If a row containing [variable-length columns](#) exceeds the [InnoDB](#) maximum row size, [InnoDB](#) selects variable-length columns for external off-page storage until the row fits within the [InnoDB](#) row size limit. The amount of data stored locally for variable-length columns that are stored off-page differs by row format. For more information, see [Section 14.14, “InnoDB Row Formats”](#).

- Different storage formats use different amounts of page header and trailer data, which affects the amount of storage available for rows.
 - For information about [InnoDB](#) row formats, see [Section 14.14, “InnoDB Row Formats”](#).
 - For information about [MyISAM](#) storage formats, see [Section 15.3.3, “MyISAM Table Storage Formats”](#).

Row Size Limit Examples

- The MySQL maximum row size limit of 65,535 bytes is demonstrated in the following [InnoDB](#) and [MyISAM](#) examples. The limit is enforced regardless of storage engine, even though the storage engine may be capable of supporting larger rows.

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g VARCHAR(6000)) ENGINE=InnoDB CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. You have to change some columns
to TEXT or BLOBs
```

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g VARCHAR(6000)) ENGINE=MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. You have to change some columns
to TEXT or BLOBs
```

In the following [MyISAM](#) example, changing a column to [TEXT](#) avoids the 65,535-byte row size limit and permits the operation to succeed because [BLOB](#) and [TEXT](#) columns only contribute 9 to 12 bytes toward the row size.

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g TEXT(6000)) ENGINE=MyISAM CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The operation succeeds for an [InnoDB](#) table because changing a column to [TEXT](#) avoids the MySQL 65,535-byte row size limit, and [InnoDB](#) off-page storage of variable-length columns avoids the [InnoDB](#) row size limit.

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g TEXT(6000)) ENGINE=InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

- Storage for variable-length columns includes length bytes, which are counted toward the row size. For example, a [VARCHAR\(255\) CHARACTER SET utf8mb3](#) column takes two bytes to store the length of the value, so each value can take up to 767 bytes.

The statement to create table `t1` succeeds because the columns require 32,765 + 2 bytes and 32,766 + 2 bytes, which falls within the maximum row size of 65,535 bytes:

```
mysql> CREATE TABLE t1
  (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
  ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The statement to create table `t2` fails because, although the column length is within the maximum length of 65,535 bytes, two additional bytes are required to record the length, which causes the row size to exceed 65,535 bytes:

```
mysql> CREATE TABLE t2
      (c1 VARCHAR(65535) NOT NULL)
      ENGINE = InnoDB CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

Reducing the column length to 65,533 or less permits the statement to succeed.

```
mysql> CREATE TABLE t2
      (c1 VARCHAR(65533) NOT NULL)
      ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.01 sec)
```

- For `MyISAM` tables, `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.

The statement to create table `t3` fails because `MyISAM` requires space for `NULL` columns in addition to the space required for variable-length column length bytes, causing the row size to exceed 65,535 bytes:

```
mysql> CREATE TABLE t3
      (c1 VARCHAR(32765) NULL, c2 VARCHAR(32766) NULL)
      ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

For information about `InnoDB NULL` column storage, see [Section 14.14, “InnoDB Row Formats”](#).

- `InnoDB` restricts row size (for data stored locally within the database page) to slightly less than half a database page. For example, the maximum row size is slightly less than 8KB for the 16KB `InnoDB` page size.

The statement to create table `t4` fails because the defined columns exceed the row size limit for a 16KB `InnoDB` page.

Note

`innodb_strict_mode` is enabled in the following example to ensure that `InnoDB` returns an error if the defined columns exceed the `InnoDB` row size limit. When `innodb_strict_mode` is disabled (the default), creating a table that uses `REDUNDANT` or `COMPACT` row format succeeds with a warning if the `InnoDB` row size limit is exceeded.

`DYNAMIC` and `COMPRESSED` row formats are more restrictive in this regard. Creating a table that uses `DYNAMIC` or `COMPRESSED` row format fails with an error if the `InnoDB` row size limit is exceeded, regardless of the `innodb_strict_mode` setting.

```
mysql> SET SESSION innodb_strict_mode=1;
mysql> CREATE TABLE t4 (
      c1 CHAR(255),c2 CHAR(255),c3 CHAR(255),
      c4 CHAR(255),c5 CHAR(255),c6 CHAR(255),
      c7 CHAR(255),c8 CHAR(255),c9 CHAR(255),
      c10 CHAR(255),c11 CHAR(255),c12 CHAR(255),
      c13 CHAR(255),c14 CHAR(255),c15 CHAR(255),
      c16 CHAR(255),c17 CHAR(255),c18 CHAR(255),
      c19 CHAR(255),c20 CHAR(255),c21 CHAR(255),
      c22 CHAR(255),c23 CHAR(255),c24 CHAR(255),
      c25 CHAR(255),c26 CHAR(255),c27 CHAR(255),
```

```

c28 CHAR(255),c29 CHAR(255),c30 CHAR(255),
c31 CHAR(255),c32 CHAR(255),c33 CHAR(255)
) ENGINE=InnoDB ROW_FORMAT=COMPACT DEFAULT CHARSET latin1;
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to TEXT or BLOB or using
ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED may help. In current row format, BLOB prefix of 768
bytes is stored inline.

```

8.5 Optimizing for InnoDB Tables

InnoDB is the storage engine that MySQL customers typically use in production databases where reliability and concurrency are important. Because **InnoDB** is the default storage engine in MySQL 5.5 and higher, you can expect to see **InnoDB** tables more often than before. This section explains how to optimize database operations for **InnoDB** tables.

8.5.1 Optimizing Storage Layout for InnoDB Tables

- Once your data reaches a stable size, or a growing table has increased by tens or some hundreds of megabytes, consider using the `OPTIMIZE TABLE` statement to reorganize the table and compact any wasted space. The reorganized tables require less disk I/O to perform full table scans. This is a straightforward technique that can improve performance when other techniques such as improving index usage or tuning application code are not practical.

`OPTIMIZE TABLE` copies the data part of the table and rebuilds the indexes. The benefits come from improved packing of data within indexes, and reduced fragmentation within the tablespaces and on disk. The benefits vary depending on the data in each table. You may find that there are significant gains for some and not for others, or that the gains decrease over time until you next optimize the table. This operation can be slow if the table is large or if the indexes being rebuilt do not fit into the buffer pool. The first run after adding a lot of data to a table is often much slower than later runs.

- In **InnoDB**, having a long **PRIMARY KEY** (either a single column with a lengthy value, or several columns that form a long composite value) wastes a lot of disk space. The primary key value for a row is duplicated in all the secondary index records that point to the same row. (See [Section 14.9.2.1, “Clustered and Secondary Indexes”](#).) Create an `AUTO_INCREMENT` column as the primary key if your primary key is long, or index a prefix of a long `VARCHAR` column instead of the entire column.
- Use the `VARCHAR` data type instead of `CHAR` to store variable-length strings or for columns with many `NULL` values. A `CHAR(N)` column always takes *N* characters to store data, even if the string is shorter or its value is `NULL`. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using `COMPACT` row format (the default **InnoDB** format) and variable-length character sets, such as `utf8` or `sjis`, `CHAR(N)` columns occupy a variable amount of space, but still at least *N* bytes.

- For tables that are big, or contain lots of repetitive text or numeric data, consider using `COMPRESSED` row format. Less disk I/O is required to bring data into the buffer pool, or to perform full table scans. Before making a permanent decision, measure the amount of compression you can achieve by using `COMPRESSED` versus `COMPACT` row format.

8.5.2 Optimizing InnoDB Transaction Management

To optimize **InnoDB** transaction processing, find the ideal balance between the performance overhead of transactional features and the workload of your server. For example, an application might encounter performance issues if it commits thousands of times per second, and different performance issues if it commits only every 2-3 hours.

- The default MySQL setting `AUTOCOMMIT=1` can impose performance limitations on a busy database server. Where practical, wrap several related data change operations into a single transaction, by issuing `SET AUTOCOMMIT=0` or a `START TRANSACTION` statement, followed by a `COMMIT` statement after making all the changes.

InnoDB must flush the log to disk at each transaction commit if that transaction made modifications to the database. When each change is followed by a commit (as with the default autocommit setting), the I/O throughput of the storage device puts a cap on the number of potential operations per second.

- Avoid performing rollbacks after inserting, updating, or deleting huge numbers of rows. If a big transaction is slowing down server performance, rolling it back can make the problem worse, potentially taking several times as long to perform as the original data change operations. Killing the database process does not help, because the rollback starts again on server startup.

To minimize the chance of this issue occurring:

- Increase the size of the [buffer pool](#) so that all the data change changes can be cached rather than immediately written to disk.
- Set `innodb_change_buffering=all` so that update and delete operations are buffered in addition to inserts.
- Consider issuing `COMMIT` statements periodically during the big data change operation, possibly breaking a single delete or update into multiple statements that operate on smaller numbers of rows.

To get rid of a runaway rollback once it occurs, increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or kill the server and restart with `innodb_force_recovery=3`, as explained in [Section 14.21.2, “InnoDB Recovery”](#).

This issue is expected to be infrequent with the default setting `innodb_change_buffering=all`, which allows update and delete operations to be cached in memory, making them faster to perform in the first place, and also faster to roll back if needed. Make sure to use this parameter setting on servers that process long-running transactions with many inserts, updates, or deletes.

- If you can afford the loss of some of the latest committed transactions if a crash occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed. Also, set the value of `innodb_support_xa` to 0, which will reduce the number of disk flushes due to synchronizing on disk data and the binary log.
- When rows are modified or deleted, the rows and associated [undo logs](#) are not physically removed immediately, or even immediately after the transaction commits. The old data is preserved until transactions that started earlier or concurrently are finished, so that those transactions can access the previous state of modified or deleted rows. Thus, a long-running transaction can prevent InnoDB from purging data that was changed by a different transaction.
- When rows are modified or deleted within a long-running transaction, other transactions using the `READ COMMITTED` and `REPEATABLE READ` isolation levels have to do more work to reconstruct the older data if they read those same rows.
- When a long-running transaction modifies a table, queries against that table from other transactions do not make use of the [covering index](#) technique. Queries that normally could retrieve all the result columns from a secondary index, instead look up the appropriate values from the table data.

If secondary index pages are found to have a `PAGE_MAX_TRX_ID` that is too new, or if records in the secondary index are delete-marked, InnoDB may need to look up records using a clustered index.

8.5.3 Optimizing InnoDB Redo Logging

Consider the following guidelines for optimizing redo logging:

- Make your redo log files big, even as big as the [buffer pool](#). When InnoDB has written the redo log files full, it must write the modified contents of the buffer pool to disk in a [checkpoint](#). Small redo log

files cause many unnecessary disk writes. Although historically big redo log files caused lengthy recovery times, recovery is now much faster and you can confidently use large redo log files.

The size and number of redo log files are configured using the `innodb_log_file_size` and `innodb_log_files_in_group` configuration options. For information about modifying an existing redo log file configuration, see [Changing the Number or Size of InnoDB Redo Log Files](#).

- Consider increasing the size of the `log buffer`. A large log buffer enables large `transactions` to run without a need to write the log to disk before the transactions `commit`. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. Log buffer size is configured using the `innodb_log_buffer_size` configuration option.

8.5.4 Bulk Data Loading for InnoDB Tables

These performance tips supplement the general guidelines for fast inserts in [Section 8.2.4.1, “Optimizing INSERT Statements”](#).

- When importing data into `InnoDB`, turn off autocommit mode, because it performs a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET autocommit` and `COMMIT` statements:

```
SET autocommit=0;... SQL import statements ...
COMMIT;
```

The `mysqldump` option `--opt` creates dump files that are fast to import into an `InnoDB` table, even without wrapping them with the `SET autocommit` and `COMMIT` statements.

- If you have `UNIQUE` constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET unique_checks=0;... SQL import statements ...
SET unique_checks=1;
```

For big tables, this saves a lot of disk I/O because `InnoDB` can use its change buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.

- If you have `FOREIGN KEY` constraints in your tables, you can speed up table imports by turning off the foreign key checks for the duration of the import session:

```
SET foreign_key_checks=0;... SQL import statements ...
SET foreign_key_checks=1;
```

For big tables, this can save a lot of disk I/O.

- Use the multiple-row `INSERT` syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just `InnoDB` tables.

- When doing bulk inserts into tables with auto-increment columns, set `innodb_autoinc_lock_mode` to 2 instead of the default value 1. See [Section 14.9.1.4, “AUTO_INCREMENT Handling in InnoDB”](#) for details.
- When performing bulk inserts, it is faster to insert rows in `PRIMARY KEY` order. `InnoDB` tables use a `clustered index`, which makes it relatively fast to use data in the order of the `PRIMARY KEY`. Performing bulk inserts in `PRIMARY KEY` order is particularly important for tables that do not fit entirely within the buffer pool.

8.5.5 Optimizing InnoDB Queries

To tune queries for [InnoDB](#) tables, create an appropriate set of indexes on each table. See [Section 8.3.1, “How MySQL Uses Indexes”](#) for details. Follow these guidelines for [InnoDB](#) indexes:

- Because each [InnoDB](#) table has a [primary key](#) (whether you request one or not), specify a set of primary key columns for each table, columns that are used in the most important and time-critical queries.
- Do not specify too many or too long columns in the primary key, because these column values are duplicated in each secondary index. When an index contains unnecessary data, the I/O to read this data and memory to cache it reduce the performance and scalability of the server.
- Do not create a separate [secondary index](#) for each column, because each query can only make use of one index. Indexes on rarely tested columns or columns with only a few different values might not be helpful for any queries. If you have many queries for the same table, testing different combinations of columns, try to create a small number of [concatenated indexes](#) rather than a large number of single-column indexes. If an index contains all the columns needed for the result set (known as a [covering index](#)), the query might be able to avoid reading the table data at all.
- If an indexed column cannot contain any [NULL](#) values, declare it as [NOT NULL](#) when you create the table. The optimizer can better determine which index is most effective to use for a query, when it knows whether each column contains [NULL](#) values.

8.5.6 Optimizing InnoDB DDL Operations

- For DDL operations on tables and indexes ([CREATE](#), [ALTER](#), and [DROP](#) statements), the most significant aspect for [InnoDB](#) tables is that creating and dropping secondary indexes is much faster in MySQL 5.5 and higher, than in earlier versions. See [Section 14.16, “InnoDB Fast Index Creation”](#) for details.
- “Fast index creation” makes it faster in some cases to drop an index before loading data into a table, then re-create the index after loading the data.
- Use [TRUNCATE TABLE](#) to empty a table, not [DELETE FROM tbl_name](#). Foreign key constraints can make a [TRUNCATE](#) statement work like a regular [DELETE](#) statement, in which case a sequence of commands like [DROP TABLE](#) and [CREATE TABLE](#) might be fastest.
- Because the primary key is integral to the storage layout of each [InnoDB](#) table, and changing the definition of the primary key involves reorganizing the whole table, always set up the primary key as part of the [CREATE TABLE](#) statement, and plan ahead so that you do not need to [ALTER](#) or [DROP](#) the primary key afterward.

8.5.7 Optimizing InnoDB Disk I/O

If you follow best practices for database design and tuning techniques for SQL operations, but your database is still slow due to heavy disk I/O activity, consider these disk I/O optimizations. If the Unix [top](#) tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound.

- Increase buffer pool size

When table data is cached in the [InnoDB](#) buffer pool, it can be accessed repeatedly by queries without requiring any disk I/O. Specify the size of the buffer pool with the [innodb_buffer_pool_size](#) option. This memory area is important enough that it is typically recommended that [innodb_buffer_pool_size](#) is configured to 50 to 75 percent of system memory. For more information see, [Section 8.12.4.1, “How MySQL Uses Memory”](#).

- Adjust the flush method

In some versions of GNU/Linux and Unix, flushing files to disk with the Unix [fsync\(\)](#) call (which [InnoDB](#) uses by default) and similar methods is surprisingly slow. If database write performance is an issue, conduct benchmarks with the [innodb_flush_method](#) parameter set to [O_DSYNC](#).

- Use a noop or deadline I/O scheduler with native AIO on Linux

InnoDB uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the `innodb_use_native_aio` configuration option, which is enabled by default. With native AIO, the type of I/O scheduler has greater influence on I/O performance. Generally, noop and deadline I/O schedulers are recommended. Conduct benchmarks to determine which I/O scheduler provides the best results for your workload and environment. For more information, see [Section 14.11.6, “Using Asynchronous I/O on Linux”](#).

- Use direct I/O on Solaris 10 for x86_64 architecture

When using the InnoDB storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), use direct I/O for InnoDB-related files to avoid degradation of InnoDB performance. To use direct I/O for an entire UFS file system used for storing InnoDB-related files, mount it with the `forcedirectio` option; see `mount_ufs(1M)`. (The default on Solaris 10/x86_64 is *not* to use this option.) To apply direct I/O only to InnoDB file operations rather than the whole file system, set `innodb_flush_method = O_DIRECT`. With this setting, InnoDB calls `directio()` instead of `fcntl()` for I/O to data files (not for I/O to log files).

- Use raw storage for data and log files with Solaris 2.6 or later

When using the InnoDB storage engine with a large `innodb_buffer_pool_size` value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), conduct benchmarks with InnoDB data files and log files on raw devices or on a separate direct I/O UFS file system, using the `forcedirectio` mount option as described previously. (It is necessary to use the mount option rather than setting `innodb_flush_method` if you want direct I/O for the log files.) Users of the Veritas file system VxFS should use the `convosync=direct` mount option.

Do not place other MySQL data files, such as those for MyISAM tables, on a direct I/O file system. Executables or libraries *must not* be placed on a direct I/O file system.

- Use additional storage devices

Additional storage devices could be used to set up a RAID configuration. For related information, see [Section 8.12.2, “Optimizing Disk I/O”](#).

Alternatively, InnoDB tablespace data files and log files can be placed on different physical disks. For more information, refer to the following sections:

- [Section 14.11.1, “InnoDB Startup Configuration”](#)
- [Section 14.9.1.2, “Moving or Copying InnoDB Tables”](#)

- Non-rotational storage generally provides better performance for random I/O operations; and rotational storage for sequential I/O operations. When distributing data and log files across rotational and non-rotational storage devices, consider the type of I/O operations that are predominantly performed on each file.

Random I/O-oriented files are typically [file-per-table](#) data files. Sequential I/O-oriented files include InnoDB [system tablespace](#) files (due to [doublewrite buffering](#) and [change buffering](#)) and log files such as [binary log](#) files and [redo log](#) files.

Review settings for the following configuration options when using non-rotational storage:

- `innodb_io_capacity`

The default setting of 200 is generally sufficient for a lower-end non-rotational storage device. For higher-end, bus-attached devices, consider a higher setting such as 1000.

- `innodb_log_file_size`

If redo logs are on non-rotational storage, configure this option to maximize caching and write combining.

Early-generation SSD devices often have a 4KB sector size, but some newer devices have a 16KB sector size. The default `InnoDB` page size is 16KB. Keeping the page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

Ensure that TRIM support is enabled for your operating system. It is typically enabled by default.

- Increase I/O capacity to avoid backlogs

If throughput drops periodically because of `InnoDB checkpoint` operations, consider increasing the value of the `innodb_io_capacity` configuration option. Higher values cause more frequent `flushing`, avoiding the backlog of work that can cause dips in throughput.

- Lower I/O capacity if flushing does not fall behind

If the system is not falling behind with `InnoDB flushing` operations, consider lowering the value of the `innodb_io_capacity` configuration option. Typically, you keep this option value as low as practical, but not so low that it causes periodic drops in throughput as mentioned in the preceding bullet. In a typical scenario where you could lower the option value, you might see a combination like this in the output from `SHOW ENGINE INNODB STATUS`:

- History list length low, below a few thousand.
- Insert buffer merges close to rows inserted.
- Modified pages in buffer pool consistently well below `innodb_max_dirty_pages_pct` of the buffer pool. (Measure at a time when the server is not doing bulk inserts; it is normal during bulk inserts for the modified pages percentage to rise significantly.)
- `Log sequence number - Last checkpoint` is at less than 7/8 or ideally less than 6/8 of the total size of the `InnoDB log files`.

8.5.8 Optimizing InnoDB Configuration Variables

Different settings work best for servers with light, predictable loads, versus servers that are running near full capacity all the time, or that experience spikes of high activity.

Because the `InnoDB` storage engine performs many of its optimizations automatically, many performance-tuning tasks involve monitoring to ensure that the database is performing well, and changing configuration options when performance drops. See [Section 14.19, “InnoDB Integration with MySQL Performance Schema”](#) for information about detailed `InnoDB` performance monitoring.

For a list of the most important and most recent `InnoDB` performance features, see [Section 1.4, “What Is New in MySQL 5.5”](#). Even if you have used `InnoDB` tables in prior versions, these features might be new to you, because they are from the “`InnoDB` Plugin”. The Plugin co-existed alongside the built-in `InnoDB` in MySQL 5.1, and becomes the default storage engine in MySQL 5.5 and higher.

The main configuration steps you can perform include:

- Enabling `InnoDB` to use high-performance memory allocators on systems that include them. See [Section 14.11.3, “Configuring the Memory Allocator for InnoDB”](#).
- Controlling the types of data change operations for which `InnoDB` buffers the changed data, to avoid frequent small disk writes. See [Configuring Change Buffering](#). Because the default is to buffer all types of data change operations, only change this setting if you need to reduce the amount of buffering.

- Turning the adaptive hash indexing feature on and off using the `innodb_adaptive_hash_index` option. See [Section 14.8.3, “Adaptive Hash Index”](#) for more information. You might change this setting during periods of unusual activity, then restore it to its original setting.
- Setting a limit on the number of concurrent threads that InnoDB processes, if context switching is a bottleneck. See [Section 14.11.4, “Configuring Thread Concurrency for InnoDB”](#).
- Controlling the amount of prefetching that InnoDB does with its read-ahead operations. When the system has unused I/O capacity, more read-ahead can improve the performance of queries. Too much read-ahead can cause periodic drops in performance on a heavily loaded system. See [Section 14.11.2.3, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).
- Increasing the number of background threads for read or write operations, if you have a high-end I/O subsystem that is not fully utilized by the default values. See [Section 14.11.5, “Configuring the Number of Background InnoDB I/O Threads”](#).
- Controlling how much I/O InnoDB performs in the background. See [Section 14.11.7, “Configuring InnoDB I/O Capacity”](#). You might scale back this setting if you observe periodic drops in performance.
- Controlling the algorithm that determines when InnoDB performs certain types of background writes. See [Section 14.11.2.4, “Configuring Buffer Pool Flushing”](#). The algorithm works for some types of workloads but not others, so might turn off this setting if you observe periodic drops in performance.
- Taking advantage of multicore processors and their cache memory configuration, to minimize delays in context switching. See [Section 14.11.8, “Configuring Spin Lock Polling”](#).
- Preventing one-time operations such as table scans from interfering with the frequently accessed data stored in the InnoDB buffer cache. See [Section 14.11.2.2, “Making the Buffer Pool Scan Resistant”](#).
- Adjusting log files to a size that makes sense for reliability and crash recovery. InnoDB log files have often been kept small to avoid long startup times after a crash. Optimizations introduced in MySQL 5.5 speed up certain steps of the crash [recovery](#) process. In particular, scanning the [redo log](#) and applying the redo log are faster due to improved algorithms for memory management. If you have kept your log files artificially small to avoid long startup times, you can now consider increasing log file size to reduce the I/O that occurs due recycling of redo log records.
- Configuring the size and number of instances for the InnoDB buffer pool, especially important for systems with multi-gigabyte buffer pools. See [Section 14.11.2.1, “Configuring Multiple Buffer Pool Instances”](#).
- Increasing the maximum number of concurrent transactions, which dramatically improves scalability for the busiest databases. See [Section 14.9.7, “Undo Logs”](#). Although this feature does not require any action during day-to-day operation, you must perform a [slow shutdown](#) during or after upgrading the database to MySQL 5.5 to enable the higher limit.
- Moving purge operations (a type of garbage collection) into a background thread. See [Section 14.11.9, “Purge Configuration”](#). To effectively measure the results of this setting, tune the other I/O-related and thread-related configuration settings first.
- Reducing the amount of switching that InnoDB does between concurrent threads, so that SQL operations on a busy server do not queue up and form a “traffic jam”. Set a value for the `innodb_thread_concurrency` option, up to approximately 32 for a high-powered modern system. Increase the value for the `innodb_concurrency_tickets` option, typically to 5000 or so. This combination of options sets a cap on the number of threads that InnoDB processes at any one time, and allows each thread to do substantial work before being swapped out, so that the number of waiting threads stays low and operations can complete without excessive context switching.

8.5.9 Optimizing InnoDB for Systems with Many Tables

- InnoDB computes index [cardinality](#) values for a table the first time that table is accessed after startup, instead of storing such values in the table. This step can take significant time on systems that partition the data into many tables. Since this overhead only applies to the initial table open operation, to “warm up” a table for later use, access it immediately after startup by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

8.6 Optimizing for MyISAM Tables

The [MyISAM](#) storage engine performs best with read-mostly data or with low-concurrency operations, because table locks limit the ability to perform simultaneous updates. In MySQL 5.5, [InnoDB](#) is the default storage engine rather than [MyISAM](#).

8.6.1 Optimizing MyISAM Queries

Some general tips for speeding up queries on [MyISAM](#) tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the [Cardinality](#) value. `myisamchk --description --verbose` shows index distribution information.
- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.
- Try to avoid complex `SELECT` queries on [MyISAM](#) tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.
- [MyISAM](#) supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See [Section 8.11.3, “Concurrent Inserts”](#).
- For [MyISAM](#) tables that change frequently, try to avoid all variable-length columns (`VARCHAR`, `BLOB`, and `TEXT`). The table uses dynamic row format if it includes even a single variable-length column. See [Chapter 15, Alternative Storage Engines](#).
- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a [MyISAM](#) table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See [Chapter 15, Alternative Storage Engines](#).
- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.
- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is very important when you use a MySQL storage engine such as [MyISAM](#) that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- Use [INSERT DELAYED](#) when you do not need to know when your data is written. This reduces the overall insertion impact because many rows can be written with a single disk write.
- Use [INSERT LOW_PRIORITY](#) when you want to give [SELECT](#) statements higher priority than your inserts.

Use [SELECT HIGH_PRIORITY](#) to get retrievals that jump the queue. That is, the [SELECT](#) is executed even if there is another client waiting to do a write.

[LOW_PRIORITY](#) and [HIGH_PRIORITY](#) have an effect only for storage engines that use only table-level locking (such as [MyISAM](#), [MEMORY](#), and [MERGE](#)).

- Use [OPTIMIZE TABLE](#) periodically to avoid fragmentation with dynamic-format [MyISAM](#) tables. See [Section 15.3.3, “MyISAM Table Storage Formats”](#).
- Declaring a [MyISAM](#) table with the [DELAY_KEY_WRITE=1](#) table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the [myisam_recover_options](#) system variable set, or by running [myisamchk](#) before restarting the server. (However, even in this case, you should not lose anything by using [DELAY_KEY_WRITE](#), because the key information can always be generated from the data rows.)
- Strings are automatically prefix- and end-space compressed in [MyISAM](#) indexes. See [Section 13.1.13, “CREATE INDEX Statement”](#).
- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. Locking the table during this operation ensures that the index cache is only flushed once after all updates. You can also take advantage of MySQL's query cache to achieve similar results; see [Section 8.10.3, “The MySQL Query Cache”](#).

8.6.2 Bulk Data Loading for MyISAM Tables

These performance tips supplement the general guidelines for fast inserts in [Section 8.2.4.1, “Optimizing INSERT Statements”](#).

- To improve performance when multiple clients insert a lot of rows, use the [INSERT DELAYED](#) statement. See [Section 13.2.5.3, “INSERT DELAYED Statement”](#). This technique works for [MyISAM](#) and some other storage engines, but not [InnoDB](#).
- For a [MyISAM](#) table, you can use concurrent inserts to add rows at the same time that [SELECT](#) statements are running, if there are no deleted rows in middle of the data file. See [Section 8.11.3, “Concurrent Inserts”](#).
- With some extra work, it is possible to make [LOAD DATA](#) run even faster for a [MyISAM](#) table when the table has many indexes. Use the following procedure:
 1. Execute a [FLUSH TABLES](#) statement or a [mysqladmin flush-tables](#) command.
 2. Use [myisamchk --keys-used=0 -rq /path/to/db/tbl_name](#) to remove all use of indexes for the table.
 3. Insert data into the table with [LOAD DATA](#). This does not update any indexes and therefore is very fast.

4. If you intend only to read from the table in the future, use `myisampack` to compress it. See [Section 15.3.3.3, “Compressed Table Characteristics”](#).
5. Re-create the indexes with `myisamchk -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster than updating the index during `LOAD DATA` because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
6. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

`LOAD DATA` performs the preceding optimization automatically if the `MyISAM` table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the `LOAD DATA` statement.

You can also disable or enable the nonunique indexes for a `MyISAM` table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the `FLUSH TABLES` operations:

```
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up `INSERT` operations that are performed with multiple statements for nontransactional tables, lock your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all `INSERT` statements have completed. Normally, there would be as many index buffer flushes as there are `INSERT` statements. Explicit locking statements are not needed if you can insert all rows with a single `INSERT`.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

- Connection 1 does 1000 inserts
- Connections 2, 3, and 4 do 1 insert
- Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

`INSERT`, `UPDATE`, and `DELETE` operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (each 1,000 rows or so) to permit other threads to access table. This would still result in a nice performance gain.

`INSERT` is still much slower for loading data than `LOAD DATA`, even when using the strategies just outlined.

- To increase performance for `MyISAM` tables, for both `LOAD DATA` and `INSERT`, enlarge the key cache by increasing the `key_buffer_size` system variable. See [Section 5.1.1, “Configuring the Server”](#).

8.6.3 Optimizing REPAIR TABLE Statements

`REPAIR TABLE` for `MyISAM` tables is similar to using `myisamchk` for repair operations, and some of the same performance optimizations apply:

- `myisamchk` has variables that control memory allocation. You may be able to improve its performance by setting these variables, as described in [Section 4.6.3.6, “myisamchk Memory Usage”](#).
- For `REPAIR TABLE`, the same principle applies, but because the repair is done by the server, you set server system variables instead of `myisamchk` variables. Also, in addition to setting memory-allocation variables, increasing the `myisam_max_sort_file_size` system variable increases the likelihood that the repair will use the faster filesort method and avoid the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.

Suppose that a `myisamchk` table-repair operation is done using the following options to set its memory-allocation variables:

```
--key_buffer_size=128M --myisam_sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those `myisamchk` variables correspond to server system variables:

| <code>myisamchk</code> Variable | System Variable |
|--------------------------------------|--------------------------------------|
| <code>key_buffer_size</code> | <code>key_buffer_size</code> |
| <code>myisam_sort_buffer_size</code> | <code>myisam_sort_buffer_size</code> |
| <code>read_buffer_size</code> | <code>read_buffer_size</code> |
| <code>write_buffer_size</code> | none |

Each of the server system variables can be set at runtime, and some of them (`myisam_sort_buffer_size`, `read_buffer_size`) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable (`key_buffer_size`, `myisam_max_sort_file_size`) affects other users as well. For `key_buffer_size`, you must take into account that the buffer is shared with those users. For example, if you set the `myisamchk key_buffer_size` variable to 128MB, you could set the corresponding `key_buffer_size` system variable larger than that (if it is not already set larger), to permit key buffer use by activity in other sessions. However, changing the global key buffer size invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See [Section 8.10.2.2, “Multiple Key Caches”](#).

Based on the preceding remarks, a `REPAIR TABLE` operation can be done as follows to use settings similar to the `myisamchk` command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX tbl_name IN repair_cache;
LOAD INDEX INTO CACHE tbl_name;
```

```
REPAIR TABLE tbl_name ;
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a `REPAIR TABLE` operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```
SET @old_myisam_sort_buffer_size = @@GLOBAL.myisam_max_sort_file_size;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
REPAIR TABLE tbl_name ;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;
```

The system variables that affect `REPAIR TABLE` can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server `my.cnf` file:

```
[mysqld]
myisam_sort_buffer_size=256M
key_buffer_size=1G
myisam_max_sort_file_size=100G
```

These settings do not include `read_buffer_size`. Setting `read_buffer_size` globally to a large value does so for all sessions and can cause performance to suffer due to excessive memory allocation for a server with many simultaneous sessions.

8.7 Optimizing for MEMORY Tables

Consider using `MEMORY` tables for noncritical data that is accessed often, and is read-only or rarely updated. Benchmark your application against equivalent `InnoDB` or `MyISAM` tables under a realistic workload, to confirm that any additional performance is worth the risk of losing data, or the overhead of copying data from a disk-based table at application start.

For best performance with `MEMORY` tables, examine the kinds of queries against each table, and specify the type to use for each associated index, either a B-tree index or a hash index. On the `CREATE INDEX` statement, use the clause `USING BTREE` or `USING HASH`. B-tree indexes are fast for queries that do greater-than or less-than comparisons through operators such as `>` or `BETWEEN`. Hash indexes are only fast for queries that look up single values through the `=` operator, or a restricted set of values through the `IN` operator. For why `USING BTREE` is often a better choice than the default `USING HASH`, see [Section 8.2.1.16, “Avoiding Full Table Scans”](#). For implementation details of the different types of `MEMORY` indexes, see [Section 8.3.8, “Comparison of B-Tree and Hash Indexes”](#).

8.8 Understanding the Query Execution Plan

Depending on the details of your tables, columns, indexes, and the conditions in your `WHERE` clause, the MySQL optimizer considers many techniques to efficiently perform the lookups involved in an SQL query. A query on a huge table can be performed without reading all the rows; a join involving several tables can be performed without comparing every combination of rows. The set of operations that the optimizer chooses to perform the most efficient query is called the “query execution plan”, also known as the `EXPLAIN` plan. Your goals are to recognize the aspects of the `EXPLAIN` plan that indicate a query is optimized well, and to learn the SQL syntax and indexing techniques to improve the plan if you see some inefficient operations.

8.8.1 Optimizing Queries with EXPLAIN

The `EXPLAIN` statement provides information about how MySQL executes statements:

- When you precede a `SELECT` statement with the keyword `EXPLAIN`, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see [Section 8.8.2, “EXPLAIN Output Format”](#).

- `EXPLAIN EXTENDED` produces additional execution plan information that can be displayed using `SHOW WARNINGS`. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).
- `EXPLAIN PARTITIONS` is useful for examining queries involving partitioned tables. See [Section 19.3.4, “Obtaining Information About Partitions”](#).

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 13.2.9, “SELECT Statement”](#).)

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 13.7.2.1, “ANALYZE TABLE Statement”](#).

Note

`EXPLAIN` can also be used to obtain information about the columns in a table. `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` and `SHOW COLUMNS FROM tbl_name`. For more information, see [Section 13.8.1, “DESCRIBE Statement”](#), and [Section 13.7.5.6, “SHOW COLUMNS Statement”](#).

8.8.2 EXPLAIN Output Format

The `EXPLAIN` statement provides information about the execution plan for a `SELECT` statement.

`EXPLAIN` returns a row of information for each table used in the `SELECT` statement. It lists the tables in the output in the order that MySQL would read them while processing the statement. MySQL resolves all joins using a nested-loop join method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

When the `EXTENDED` keyword is used, `EXPLAIN` produces extra information that can be viewed by issuing a `SHOW WARNINGS` statement following the `EXPLAIN` statement. `EXPLAIN EXTENDED` also displays the `filtered` column. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).

Note

You cannot use the `EXTENDED` and `PARTITIONS` keywords together in the same `EXPLAIN` statement.

Note

MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See [Tutorial: Using Explain to Improve Query Performance](#).

- [EXPLAIN Output Columns](#)
- [EXPLAIN Join Types](#)
- [EXPLAIN Extra Information](#)
- [EXPLAIN Output Interpretation](#)

EXPLAIN Output Columns

This section describes the output columns produced by `EXPLAIN`. Later sections provide additional information about the `type` and `Extra` columns.

Each output row from `EXPLAIN` provides information about one table. Each row contains the values summarized in Table 8.1, “EXPLAIN Output Columns”, and described in more detail following the table.

Table 8.1 EXPLAIN Output Columns

| Column | Meaning |
|----------------------------|--|
| <code>id</code> | The <code>SELECT</code> identifier |
| <code>select_type</code> | The <code>SELECT</code> type |
| <code>table</code> | The table for the output row |
| <code>partitions</code> | The matching partitions |
| <code>type</code> | The join type |
| <code>possible_keys</code> | The possible indexes to choose |
| <code>key</code> | The index actually chosen |
| <code>key_len</code> | The length of the chosen key |
| <code>ref</code> | The columns compared to the index |
| <code>rows</code> | Estimate of rows to be examined |
| <code>filtered</code> | Percentage of rows filtered by table condition |
| <code>Extra</code> | Additional information |

- `id`

The `SELECT` identifier. This is the sequential number of the `SELECT` within the query. The value can be `NULL` if the row refers to the union result of other rows. In this case, the `table` column shows a value like `<unionM,N>` to indicate that the row refers to the union of the rows with `id` values of `M` and `N`.

- `select_type`

The type of `SELECT`, which can be any of those shown in the following table.

| <code>select_type</code> Value | Meaning |
|-----------------------------------|---|
| <code>SIMPLE</code> | Simple <code>SELECT</code> (not using <code>UNION</code> or subqueries) |
| <code>PRIMARY</code> | Outermost <code>SELECT</code> |
| <code>UNION</code> | Second or later <code>SELECT</code> statement in a <code>UNION</code> |
| <code>DEPENDENT UNION</code> | Second or later <code>SELECT</code> statement in a <code>UNION</code> , dependent on outer query |
| <code>UNION RESULT</code> | Result of a <code>UNION</code> . |
| <code>SUBQUERY</code> | First <code>SELECT</code> in subquery |
| <code>DEPENDENT SUBQUERY</code> | First <code>SELECT</code> in subquery, dependent on outer query |
| <code>DERIVED</code> | Derived table |
| <code>UNCACHEABLE SUBQUERY</code> | A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query |
| <code>UNCACHEABLE UNION</code> | The second or later select in a <code>UNION</code> that belongs to an uncacheable subquery (see <code>UNCACHEABLE SUBQUERY</code>) |

`DEPENDENT` typically signifies the use of a correlated subquery. See Section 13.2.10.7, “Correlated Subqueries”.

`DEPENDENT SUBQUERY` evaluation differs from `UNCACHEABLE SUBQUERY` evaluation. For `DEPENDENT SUBQUERY`, the subquery is re-evaluated only once for each set of different values of

the variables from its outer context. For `UNCACHEABLE SUBQUERY`, the subquery is re-evaluated for each row of the outer context.

Cacheability of subqueries differs from caching of query results in the query cache (which is described in [Section 8.10.3.1, “How the Query Cache Operates”](#)). Subquery caching occurs during query execution, whereas the query cache is used to store results only after query execution finishes.

- `table`

The name of the table to which the row of output refers. This can also be one of the following values:

- `<unionM,N>`: The row refers to the union of the rows with `id` values of `M` and `N`.
- `<derivedN>`: The row refers to the derived table result for the row with an `id` value of `N`. A derived table may result, for example, from a subquery in the `FROM` clause.

- `partitions`

The partitions from which records would be matched by the query. This column is displayed only if the `PARTITIONS` keyword is used. The value is `NULL` for nonpartitioned tables. See [Section 19.3.4, “Obtaining Information About Partitions”](#).

- `type`

The join type. For descriptions of the different types, see [EXPLAIN Join Types](#).

- `possible_keys`

The `possible_keys` column indicates the indexes from which MySQL can choose to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

If this column is `NULL`, there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with `EXPLAIN` again. See [Section 13.1.7, “ALTER TABLE Statement”](#).

To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- `key`

The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

It is possible that `key` will name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

For `InnoDB`, a secondary index might cover the selected columns even if the query also selects the primary key because `InnoDB` stores the primary key value with each secondary index. If `key` is `NULL`, MySQL found no index to use for executing the query more efficiently.

To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See [Section 8.9.3, “Index Hints”](#).

For `MyISAM` and `NDB` tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For `NDB` tables, this also improves performance of distributed pushed-down joins. For `MyISAM`

tables, `myisamchk --analyze` does the same as `ANALYZE TABLE`. See [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

- `key_len`

The `key_len` column indicates the length of the key that MySQL decided to use. The value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses. If the `key` column says `NULL`, the `len_len` column also says `NULL`.

Due to the key storage format, the key length is one greater for a column that can be `NULL` than for a `NOT NULL` column.

- `ref`

The `ref` column shows which columns or constants are compared to the index named in the `key` column to select rows from the table.

- `rows`

The `rows` column indicates the number of rows MySQL believes it must examine to execute the query.

For `InnoDB` tables, this number is an estimate, and may not always be exact.

- `filtered`

The `filtered` column indicates an estimated percentage of table rows that will be filtered by the table condition. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering. `rows` shows the estimated number of rows examined and `rows × filtered` shows the number of rows that will be joined with the following table. For example, if `rows` is 1000 and `filtered` is 50.00 (50%), the number of rows to be joined with the following table is $1000 \times 50\% = 500$. This column is displayed if you use `EXPLAIN EXTENDED`.

- `Extra`

This column contains additional information about how MySQL resolves the query. For descriptions of the different values, see [EXPLAIN Extra Information](#).

EXPLAIN Join Types

The `type` column of `EXPLAIN` output describes how tables are joined. The following list describes the join types, ordered from the best type to the worst:

- `system`

The table has only one row (= system table). This is a special case of the `const` join type.

- `const`

The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` tables are very fast because they are read only once.

`const` is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index to constant values. In the following queries, `tbl_name` can be used as a `const` table:

```
SELECT * FROM tbl_name WHERE primary_key=1;

SELECT * FROM tbl_name
WHERE primary_key_part1=1 AND primary_key_part2=2;
```

- `eq_ref`

One row is read from this table for each combination of rows from the previous tables. Other than the `system` and `const` types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE NOT NULL` index.

`eq_ref` can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` join to process `ref_table`:

```
SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column_part1=other_table.column
     AND ref_table.key_column_part2=1;
```

- `ref`

All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

`ref` can be used for indexed columns that are compared using the `=` or `<=>` operator. In the following examples, MySQL can use a `ref` join to process `ref_table`:

```
SELECT * FROM ref_table WHERE key_column=expr;

SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column_part1=other_table.column
     AND ref_table.key_column_part2=1;
```

- `fulltext`

The join is performed using a `FULLTEXT` index.

- `ref_or_null`

This join type is like `ref`, but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a `ref_or_null` join to process `ref_table`:

```
SELECT * FROM ref_table
  WHERE key_column=expr OR key_column IS NULL;
```

See [Section 8.2.1.9, “IS NULL Optimization”](#).

- `index_merge`

This join type indicates that the Index Merge optimization is used. In this case, the `key` column in the output row contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see [Section 8.2.1.3, “Index Merge Optimization”](#).

- `unique_subquery`

This type replaces `eq_ref` for some `IN` subqueries of the following form:

```
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```

`unique_subquery` is just an index lookup function that replaces the subquery completely for better efficiency.

- `index_subquery`

This join type is similar to `unique_subquery`. It replaces `IN` subqueries, but it works for nonunique indexes in subqueries of the following form:

```
value IN (SELECT key_column FROM single_table WHERE some_expr)
```

- `range`

Only rows that are in a given range are retrieved, using an index to select the rows. The `key` column in the output row indicates which index is used. The `key_len` contains the longest key part that was used. The `ref` column is `NULL` for this type.

`range` can be used when a key column is compared to a constant using any of the `=`, `<>`, `>`, `>=`, `<`, `<=`, `IS NULL`, `<=>`, `BETWEEN`, `LIKE`, or `IN()` operators:

```
SELECT * FROM tbl_name
  WHERE key_column = 10;

SELECT * FROM tbl_name
  WHERE key_column BETWEEN 10 and 20;

SELECT * FROM tbl_name
  WHERE key_column IN (10,20,30);

SELECT * FROM tbl_name
  WHERE key_part1 = 10 AND key_part2 IN (10,20,30);
```

- `index`

The `index` join type is the same as `ALL`, except that the index tree is scanned. This occurs two ways:

- If the index is a covering index for the queries and can be used to satisfy all data required from the table, only the index tree is scanned. In this case, the `Extra` column says `Using index`. An index-only scan usually is faster than `ALL` because the size of the index usually is smaller than the table data.
- A full table scan is performed using reads from the index to look up data rows in index order. `Uses index` does not appear in the `Extra` column.

MySQL can use this join type when the query uses only columns that are part of a single index.

- `ALL`

A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const`, and usually very bad in all other cases. Normally, you can avoid `ALL` by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

EXPLAIN Extra Information

The `Extra` column of `EXPLAIN` output contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. If you want to make your queries as fast as possible, look out for `Extra` values of `Using filesort` and `Using temporary`.

- `Child of 'table' pushed join@1`

This table is referenced as the child of `table` in a join that can be pushed down to the NDB kernel. Applies only in MySQL NDB Cluster 7.2 and later, when pushed-down joins are enabled. See the description of the `ndb_join_pushdown` server system variable for more information and examples.

- `const row not found`

For a query such as `SELECT ... FROM tbl_name`, the table was empty.

- `Distinct`

MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- `Full scan on NULL key`

This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- `Impossible HAVING`

The `HAVING` clause is always false and cannot select any rows.

- `Impossible WHERE`

The `WHERE` clause is always false and cannot select any rows.

- `Impossible WHERE noticed after reading const tables`

MySQL has read all `const` (and `system`) tables and notice that the `WHERE` clause is always false.

- `No matching min/max row`

No row satisfies the condition for a query such as `SELECT MIN(...) FROM ... WHERE condition`.

- `no matching row in const table`

For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- `No tables used`

The query has no `FROM` clause, or has a `FROM DUAL` clause.

- `Not exists`

MySQL was able to do a `LEFT JOIN` optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the `LEFT JOIN` criteria. Here is an example of the type of query that can be optimized this way:

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
WHERE t2.id IS NULL;
```

Assume that `t2.id` is defined as `NOT NULL`. In this case, MySQL scans `t1` and looks up the rows in `t2` using the values of `t1.id`. If MySQL finds a matching row in `t2`, it knows that `t2.id` can never be `NULL`, and does not scan through the rest of the rows in `t2` that have the same `id` value. In other words, for each row in `t1`, MySQL needs to do only a single lookup in `t2`, regardless of how many rows actually match in `t2`.

- `Range checked for each record (index map: N)`

MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a `range` or `index_merge` access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in [Section 8.2.1.2, “Range Optimization”](#), and [Section 8.2.1.3, “Index Merge Optimization”](#), with the exception that all column values for the preceding table are known and considered to be constants.

Indexes are numbered beginning with 1, in the same order as shown by `SHOW INDEX` for the table. The index map value *N* is a bitmask value that indicates which indexes are candidates. For example, a value of `0x19` (binary 11001) means that indexes 1, 4, and 5 will be considered.

- `Scanned N databases`

This indicates how many directory scans the server performs when processing a query for `INFORMATION_SCHEMA` tables, as described in [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#). The value of *N* can be 0, 1, or `all`.

- `Select tables optimized away`

The optimizer determined 1) that at most one row should be returned, and 2) that to produce this row, a deterministic set of rows must be read. When the rows to be read can be read during the optimization phase (for example, by reading index rows), there is no need to read any tables during query execution.

The first condition is fulfilled when the query is implicitly grouped (contains an aggregate function but no `GROUP BY` clause). The second condition is fulfilled when one row lookup is performed per index used. The number of indexes read determines the number of rows to read.

Consider the following implicitly grouped query:

```
SELECT MIN(c1), MIN(c2) FROM t1;
```

Suppose that `MIN(c1)` can be retrieved by reading one index row and `MIN(c2)` can be retrieved by reading one row from a different index. That is, for each column `c1` and `c2`, there exists an index where the column is the first column of the index. In this case, one row is returned, produced by reading two deterministic rows.

This `Extra` value does not occur if the rows to read are not deterministic. Consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 <= 10;
```

Suppose that `(c1, c2)` is a covering index. Using this index, all rows with `c1 <= 10` must be scanned to find the minimum `c2` value. By contrast, consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 = 10;
```

In this case, the first index row with `c1 = 10` contains the minimum `c2` value. Only one row must be read to produce the returned row.

For storage engines that maintain an exact row count per table (such as `MyISAM`, but not `InnoDB`), this `Extra` value can occur for `COUNT(*)` queries for which the `WHERE` clause is missing or always true and there is no `GROUP BY` clause. (This is an instance of an implicitly grouped query where the storage engine influences whether a deterministic number of rows can be read.)

- `Skip_open_table, Open_frm_only, Open_full_table`

These values indicate file-opening optimizations that apply to queries for `INFORMATION_SCHEMA` tables, as described in [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

- `Skip_open_table`: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
- `Open_frm_only`: Only the table's `.frm` file need be opened.
- `Open_full_table`: The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

- `unique row not found`

For a query such as `SELECT ... FROM tbl_name`, no rows satisfy the condition for a `UNIQUE` index or `PRIMARY KEY` on the table.

- `Using filesort`

MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the `WHERE` clause. The keys then are sorted and the rows are retrieved in sorted order. See [Section 8.2.1.10, “ORDER BY Optimization”](#).

- `Using index`

The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

For InnoDB tables that have a user-defined clustered index, that index can be used even when `Using index` is absent from the `Extra` column. This is the case if `type` is `index` and `key` is `PRIMARY`.

- `Using index for group-by`

Similar to the `Using index` table access method, `Using index for group-by` indicates that MySQL found an index that can be used to retrieve all columns of a `GROUP BY` or `DISTINCT` query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see [Section 8.2.1.11, “GROUP BY Optimization”](#).

- `Using join buffer`

Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table.

- `Using sort_union(...), Using union(...), Using intersect(...)`

These indicate the particular algorithm showing how index scans are merged for the `index_merge` join type. See [Section 8.2.1.3, “Index Merge Optimization”](#).

- `Using temporary`

To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains `GROUP BY` and `ORDER BY` clauses that list columns differently.

- `Using where`

A `WHERE` clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the `Extra` value is not `Using where` and the table join type is `ALL` or `index`. Even if you are using an index for all parts of a `WHERE` clause, you may see `Using where` if the column can be `NULL`.

- `Using where with pushed condition`

This item applies to NDB tables *only*. It means that NDB Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster's data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see [Section 8.2.1.4, “Engine Condition Pushdown Optimization”](#).

EXPLAIN Output Interpretation

You can get a good indication of how good a join is by taking the product of the values in the `rows` column of the `EXPLAIN` output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the `max_join_size` system variable, this row product also is used to determine which multiple-table `SELECT` statements to execute and which to abort. See [Section 5.1.1, “Configuring the Server”](#).

The following example shows how a multiple-table join can be optimized progressively based on the information provided by `EXPLAIN`.

Suppose that you have the `SELECT` statement shown here and that you plan to examine it using `EXPLAIN`:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
             tt.ProjectReference, tt.EstimatedShipDate,
             tt.ActualShipDate, tt.ClientID,
             tt.ServiceCodes, tt.RepetitiveID,
             tt.CurrentProcess, tt.CurrentDPPerson,
             tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
             et_1.COUNTRY, do.CUSTNAME
FROM tt, et, et AS et_1, do
WHERE tt.SubmitTime IS NULL
      AND tt.ActualPC = et.EMPLOYID
      AND tt.AssignedPC = et_1.EMPLOYID
      AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows.

| Table | Column | Data Type |
|-------|------------|-----------|
| tt | ActualPC | CHAR(10) |
| tt | AssignedPC | CHAR(10) |
| tt | ClientID | CHAR(10) |
| et | EMPLOYID | CHAR(15) |
| do | CUSTNMBR | CHAR(15) |

- The tables have the following indexes.

| Table | Index |
|-------|------------------------|
| tt | ActualPC |
| tt | AssignedPC |
| tt | ClientID |
| et | EMPLOYID (primary key) |
| do | CUSTNMBR (primary key) |

- The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

```
table type possible_keys key key_len ref rows Extra
et ALL PRIMARY NULL NULL NULL 74
do ALL PRIMARY NULL NULL NULL 2135
et_1 ALL PRIMARY NULL NULL NULL 74
tt ALL AssignedPC, NULL NULL NULL 3872
    ClientID,
    ActualPC
Range checked for each record (index map: 0x23)
```

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$ rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

| table | type | possible_keys | key | key_len | ref | rows | Extra | |
|-------|--------|--|---------|---------|-------------|------|----------------|--|
| tt | ALL | AssignedPC, ClientID, ActualPC | NULL | NULL | NULL | 3872 | Using where | |
| do | ALL | PRIMARY | NULL | NULL | NULL | 2135 | | |
| | | Range checked for each record (index map: 0x1) | | | | | | |
| et_1 | ALL | PRIMARY | NULL | NULL | NULL | 74 | | |
| | | Range checked for each record (index map: 0x1) | | | | | | |
| et | eq_ref | PRIMARY | PRIMARY | 15 | tt.ActualPC | 1 | | |

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),  
MODIFY ClientID VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

| table | type | possible_keys | key | key_len | ref | rows | Extra |
|-------|--------|--------------------------------------|----------|---------|---------------|------|----------------|
| et | ALL | PRIMARY | NULL | NULL | NULL | 74 | |
| tt | ref | AssignedPC, ClientID, ActualPC | ActualPC | 15 | et.EMPLOYID | 52 | Using where |
| et_1 | eq_ref | PRIMARY | PRIMARY | 15 | tt.AssignedPC | 1 | |
| do | eq_ref | PRIMARY | PRIMARY | 15 | tt.ClientID | 1 | |

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

| table | type | possible_keys | key | key_len | ref | rows | Extra |
|-------|--------|--------------------------------------|---------|---------|---------------|------|----------------|
| tt | ALL | AssignedPC, ClientID, ActualPC | NULL | NULL | NULL | 3872 | Using where |
| et | eq_ref | PRIMARY | PRIMARY | 15 | tt.ActualPC | 1 | |
| et_1 | eq_ref | PRIMARY | PRIMARY | 15 | tt.AssignedPC | 1 | |
| do | eq_ref | PRIMARY | PRIMARY | 15 | tt.ClientID | 1 | |

The `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. Check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better

performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause.

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see [Section 13.2.10.8, “Derived Tables”](#).

8.8.3 Extended EXPLAIN Output Format

When `EXPLAIN` is used with the `EXTENDED` keyword, the output includes a `filtered` column not otherwise displayed. This column indicates the estimated percentage of table rows that will be filtered by the table condition.

In addition, the statement produces extra (“extended”) information that is not part of `EXPLAIN` output but can be viewed by issuing a `SHOW WARNINGS` statement following `EXPLAIN`. The `Message` value in `SHOW WARNINGS` output displays how the optimizer qualifies table and column names in the `SELECT` statement, what the `SELECT` looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

Here is an example of extended `EXPLAIN` output:

```
mysql> EXPLAIN EXTENDED
      SELECT t1.a, t1.a IN (SELECT t2.a FROM t2) FROM t1\G
***** 1. row *****
      id: 1
      select_type: PRIMARY
      table: t1
      type: index
possible_keys: NULL
      key: PRIMARY
      key_len: 4
      ref: NULL
      rows: 4
      filtered: 100.00
      Extra: Using index
***** 2. row *****
      id: 2
      select_type: DEPENDENT SUBQUERY
      table: t2
      type: index_subquery
possible_keys: a
      key: a
      key_len: 5
      ref: func
      rows: 2
      filtered: 100.00
      Extra: Using index
2 rows in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
      Code: 1003
Message: select `test`.`t1`.`a` AS `a`,
      <in_optimizer>(`test`.`t1`.`a`,
      <exists>(<index_lookup>(<cache>(`test`.`t1`.`a`)
      in t2 on a checking NULL having
      <is_not_null_test>(`test`.`t2`.`a`)))) AS `t1.a`
      IN (SELECT t2.a FROM t2)` from `test`.`t1`
1 row in set (0.00 sec)
```

Because the statement displayed by `SHOW WARNINGS` may contain special markers to provide information about query rewriting or optimizer actions, the statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with `Message` values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in the extended output displayed by `SHOW WARNINGS`:

- `<cache>(expr)`

The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use.

- `<exists>(query fragment)`

The subquery predicate is converted to an `EXISTS` predicate and the subquery is transformed so that it can be used together with the `EXISTS` predicate.

- `<in_optimizer>(query fragment)`

This is an internal optimizer object with no user significance.

- `<index_lookup>(query fragment)`

The query fragment is processed using an index lookup to find qualifying rows.

- `<is_not_null_test>(expr)`

A test to verify that the expression does not evaluate to `NULL`.

- `<primary_index_lookup>(query fragment)`

The query fragment is processed using a primary key lookup to find qualifying rows.

- `<ref_null_helper>(expr)`

This is an internal optimizer object with no user significance.

When some tables are of `const` or `system` type, expressions involving columns from these tables are evaluated early by the optimizer and are not part of the displayed statement. However, with `FORMAT=JSON`, some `const` table accesses are displayed as a `ref` access that uses a `const` value.

8.8.4 Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row: $\log(\text{row_count}) / \log(\text{index_block_length} / 3 * 2 / (\text{index_length} + \text{data_pointer_length})) + 1$.

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates $\log(500,000) / \log(1024/3*2/(3+4)) + 1 = 4$ seeks.

This index would require storage of about $500,000 * 7 * 3/2 = 5.2\text{MB}$ (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

The preceding discussion does not mean that your application performance slowly degenerates by $\log N$. As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by $\log N$). To avoid this, increase the key cache size as the data grows. For `MyISAM` tables, the key cache size is controlled by the `key_buffer_size` system variable. See [Section 5.1.1, “Configuring the Server”](#).

8.9 Controlling the Query Optimizer

MySQL provides optimizer control through system variables that affect how query plans are evaluated, switchable optimizations, and index hints.

8.9.1 Controlling Query Plan Evaluation

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7 to 10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server’s performance.

A more flexible method for query optimization enables the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled using two system variables:

- The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of “educated guess” rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.
- The `optimizer_search_depth` variable tells how far into the “future” of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values of `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this variable can be set to 0 to tell the optimizer to determine the value automatically.

8.9.2 Switchable Optimizations

The `optimizer_switch` system variable enables control over optimizer behavior. Its value is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on
```

To change the value of `optimizer_switch`, assign a value consisting of a comma-separated list of one or more commands:

```
SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';
```

Each *command* value should have one of the forms shown in the following table.

| Command Syntax | Meaning |
|-------------------------------|---|
| <code>default</code> | Reset every optimization to its default value |
| <code>opt_name=default</code> | Set the named optimization to its default value |
| <code>opt_name=off</code> | Disable the named optimization |
| <code>opt_name=on</code> | Enable the named optimization |

The order of the commands in the value does not matter, although the `default` command is executed first if present. Setting an `opt_name` flag to `default` sets it to whichever of `on` or `off` is its default value. Specifying any given `opt_name` more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of `optimizer_switch` unchanged.

The following list describes the permissible `opt_name` flag names, grouped by optimization strategy:

- Engine Condition Pushdown Flags
 - `engine_condition_pushdown` (default `on`)
Controls engine condition pushdown.
- Index Merge Flags
 - `index_merge` (default `on`)
Controls all Index Merge optimizations.
 - `index_merge_intersection` (default `on`)
Controls the Index Merge Intersection Access optimization.
 - `index_merge_sort_union` (default `on`)
Controls the Index Merge Sort-Union Access optimization.
 - `index_merge_union` (default `on`)
Controls the Index Merge Union Access optimization.

For more information, see [Section 8.2.1.3, “Index Merge Optimization”](#).

When you assign a value to `optimizer_switch`, flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer will perform better without them, set the variable value like this:

```
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';
```

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=off,
                    index_merge_sort_union=off,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on
```

8.9.3 Index Hints

Index hints give the optimizer information about how to choose indexes during query processing. Index hints apply only to `SELECT` and `UPDATE` statements.

Index hints are specified following a table name. (For the general syntax for specifying tables in a `SELECT` statement, see [Section 13.2.9.2, “JOIN Clause”](#).) The syntax for referring to an individual table, including index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]

index_hint_list:
    index_hint [index_hint] ...

index_hint:
    USE {INDEX|KEY}
        [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
    | {IGNORE|FORCE} {INDEX|KEY}
        [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])

index_list:
    index_name [, index_name] ...
```

The `USE INDEX (index_list)` hint tells MySQL to use only one of the named indexes to find rows in the table. The alternative syntax `IGNORE INDEX (index_list)` tells MySQL to not use some particular index or indexes. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.

The `FORCE INDEX` hint acts like `USE INDEX (index_list)`, with the addition that a table scan is assumed to be *very* expensive. In other words, a table scan is used only if there is no way to use one of the named indexes to find rows in the table.

Each hint requires index names, not column names. To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA.STATISTICS` table.

An `index_name` value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

Examples:

```
SELECT * FROM table1 USE INDEX (col1_index,col2_index)
    WHERE col1=1 AND col2=2 AND col3=3;

SELECT * FROM table1 IGNORE INDEX (col3_index)
    WHERE col1=1 AND col2=2 AND col3=3;
```

The syntax for index hints has the following characteristics:

- It is syntactically valid to omit `index_list` for `USE INDEX`, which means “use no indexes.” Omitting `index_list` for `FORCE INDEX` or `IGNORE INDEX` is a syntax error.
- You can specify the scope of an index hint by adding a `FOR` clause to the hint. This provides more fine-grained control over optimizer selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use `FOR JOIN`. To influence index usage for sorting or grouping rows, use `FOR ORDER BY` or `FOR GROUP BY`.
- You can specify multiple index hints:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```

It is not an error to name the same index in several hints (even within the same hint):

```
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix `USE INDEX` and `FORCE INDEX` for the same table:

```
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

If an index hint includes no `FOR` clause, the scope of the hint is to apply to all parts of the statement. For example, this hint:

```
IGNORE INDEX (i1)
```

is equivalent to this combination of hints:

```
IGNORE INDEX FOR JOIN (i1)
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```

In MySQL 5.0, hint scope with no `FOR` clause was to apply only to row retrieval. To cause the server to use this older behavior when no `FOR` clause is present, enable the `old` system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

When index hints are processed, they are collected in a single list by type (`USE`, `FORCE`, `IGNORE`) and by scope (`FOR JOIN`, `FOR ORDER BY`, `FOR GROUP BY`). For example:

```
SELECT * FROM t1
  USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
  USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. `{USE|FORCE} INDEX` is applied if present. (If not, the optimizer-determined set of indexes is used.)
2. `IGNORE INDEX` is applied over the result of the previous step. For example, the following two queries are equivalent:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);

SELECT * FROM t1 USE INDEX (i1);
```

For `FULLTEXT` searches, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, `IGNORE INDEX(i1)` is ignored with no warning and the index is still used.
- For boolean mode searches, index hints with `FOR ORDER BY` or `FOR GROUP BY` are silently ignored. Index hints with `FOR JOIN` or no `FOR` modifier are honored. In contrast to how hints apply for non-`FULLTEXT` searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-`FULLTEXT` index.

For example, the following two queries are equivalent:

```
SELECT * FROM t
  USE INDEX (index1)
  IGNORE INDEX (index1) FOR ORDER BY
  IGNORE INDEX (index1) FOR GROUP BY
  WHERE ... IN BOOLEAN MODE ... ;
```

```
SELECT * FROM t
USE INDEX (index1)
WHERE ... IN BOOLEAN MODE ... ;
```

8.10 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance. Depending on your database architecture, you balance the size and layout of these areas, to provide the most performance benefit without wasting memory or exceeding available memory. When you set up or resize these memory areas, test the resulting performance using the techniques from [Section 8.13, “Measuring Performance \(Benchmarking\)”](#).

8.10.1 InnoDB Buffer Pool Optimization

[InnoDB](#) maintains a storage area called the [buffer pool](#) for caching data and indexes in memory. Knowing how the [InnoDB](#) buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning.

For an explanation of the inner workings of the [InnoDB](#) buffer pool, an overview of its LRU replacement algorithm, and general configuration information, see [Section 14.8.1, “Buffer Pool”](#).

For additional [InnoDB](#) buffer pool configuration and tuning information, see these sections:

- [Section 14.11.2.3, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#)
- [Section 14.11.2.4, “Configuring Buffer Pool Flushing”](#)
- [Section 14.11.2.2, “Making the Buffer Pool Scan Resistant”](#)
- [Section 14.11.2.1, “Configuring Multiple Buffer Pool Instances”](#)

8.10.2 The MyISAM Key Cache

To minimize disk I/O, the [MyISAM](#) storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table pages in memory:

- For index blocks, a special structure called the *key cache* (or *key buffer*) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the [MyISAM](#) key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Multiple sessions can access the cache concurrently.
- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the [key_buffer_size](#) system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the [key_buffer_size](#) value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the [MyISAM](#) index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an *LRU (Least Recently Used)* strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (*LRU chain*) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The [InnoDB](#) storage engine also uses an LRU algorithm, to manage its buffer pool. See [Section 14.8.1, “Buffer Pool”](#).

8.10.2.1 Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

- A buffer that is not being updated can be accessed by multiple sessions.
- A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
- Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

8.10.2.2 Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given [MyISAM](#) table. By default, all [MyISAM](#) table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the [CACHE INDEX](#) statement (see [Section 13.7.6.2, “CACHE INDEX Statement”](#)). For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+-----+-----+-----+-----+
| Table | Op           | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+-----+-----+-----+-----+
```

The key cache referred to in a [CACHE INDEX](#) statement can be created by setting its size with a [SET GLOBAL](#) parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

You cannot destroy the default key cache. Any attempt to do this is ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;

mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| key_buffer_size | 8384512 |
+-----+-----+
```

Key cache variables are structured system variables that have a name and components. For `keycache1.key_buffer_size`, `keycache1` is the cache variable name and `key_buffer_size` is the cache component. See [Section 5.1.8.3, “Structured System Variables”](#), for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.
- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The `CACHE INDEX` statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init_file` system variable that names a file containing `CACHE INDEX` statements to be executed. For example:

```
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysql_d_init.sql
```

The statements in `mysqld_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

8.10.2.3 Midpoint Insertion Strategy

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the *midpoint insertion strategy*.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short,” always containing at least `key_cache_division_limit` percent of the key cache blocks. `key_cache_division_limit` is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing N blocks, the block at the beginning of the hot sublist not accessed within the last $N * \text{key_cache_age_threshold} / 100$ hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

8.10.2.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op          | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
```

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the nonleaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

8.10.2.5 Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the `.MYI` index file of `MyISAM` tables, use the `--myisam-block-size` option at server startup.

8.10.2.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

8.10.3 The MySQL Query Cache

The query cache stores the text of a `SELECT` statement together with the corresponding result that was sent to the client. If an identical statement is received later, the server retrieves the results from the query cache rather than parsing and executing the statement again. The query cache is shared among sessions, so a result set generated by one client can be sent in response to the same query issued by another client.

The query cache can be useful in an environment where you have tables that do not change very often and for which the server receives many identical queries. This is a typical situation for many Web servers that generate many dynamic pages based on database content. For example, when an order form queries a table to display the lists of all US states or all countries in the world, those values can be retrieved from the query cache. Although the values would probably be retrieved from memory in any case (from the `InnoDB` buffer pool or `MyISAM` key cache), using the query cache avoids the overhead of processing the query, deciding whether to use a table scan, and locating the data block for each row.

The query cache always contains current and reliable data. Any insert, update, delete, or other modification to a table causes any relevant entries in the query cache to be flushed.

**Note**

The query cache does not work in an environment where you have multiple `mysqld` servers updating the same `MyISAM` tables.

The query cache is used for prepared statements under the conditions described in [Section 8.10.3.1, “How the Query Cache Operates”](#).

**Note**

As of MySQL 5.5.23, the query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries. (Bug #53775)

Some performance data for the query cache follows. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2x500MHz system with 2GB RAM and a 64MB query cache.

- If all the queries you are performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.
- Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` system variable to 0. By disabling the query cache code, there is no noticeable overhead.

The query cache offers the potential for substantial performance improvement, but do not assume that it will do so under all circumstances. With some query cache configurations or server workloads, you might actually see a performance decrease:

- Be cautious about sizing the query cache excessively large, which increases the overhead required to maintain the cache, possibly beyond the benefit of enabling it. Sizes in tens of megabytes are usually beneficial. Sizes in the hundreds of megabytes might not be.
- Server workload has a significant effect on query cache efficiency. A query mix consisting almost entirely of a fixed set of `SELECT` statements is much more likely to benefit from enabling the cache than a mix in which frequent `INSERT` statements cause continual invalidation of results in the cache. In some cases, a workaround is to use the `SQL_NO_CACHE` option to prevent results from even entering the cache for `SELECT` statements that use frequently modified tables. (See [Section 8.10.3.2, “Query Cache SELECT Options”](#).)

To verify that enabling the query cache is beneficial, test the operation of your MySQL server with the cache enabled and disabled. Then retest periodically because query cache efficiency may change as server workload changes.

8.10.3.1 How the Query Cache Operates

This section describes how the query cache works when it is operational. [Section 8.10.3.3, “Query Cache Configuration”](#), describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be *exactly* the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases,

different protocol versions, or different default character sets are considered different queries and are cached separately.

The cache is not used for queries of the following types:

- Queries that are a subquery of an outer query
- Queries executed within the body of a stored function, trigger, or event

Before a query result is fetched from the query cache, MySQL checks whether the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See [Section 8.10.3.4, “Query Cache Status and Maintenance”](#).

If a table changes, all cached queries that use the table become invalid and are removed from the cache. This includes queries that use `MERGE` tables that map to the changed table. A table can be changed by many types of statements, such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, `ALTER TABLE`, `DROP TABLE`, or `DROP DATABASE`.

The query cache also works within transactions when using `InnoDB` tables.

The result from a `SELECT` query on a view is cached.

The query cache works for `SELECT SQL_CALC_FOUND_ROWS . . .` queries and stores a value that is returned by a following `SELECT FOUND_ROWS()` query. `FOUND_ROWS()` returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache. The `SELECT FOUND_ROWS()` query itself cannot be cached.

Prepared statements that are issued using the binary protocol using `mysql_stmt_prepare()` and `mysql_stmt_execute()` (see [Section 23.7.7, “C API Prepared Statements”](#)), are subject to limitations on caching. Comparison with statements in the query cache is based on the text of the statement after expansion of `?` parameter markers. The statement is compared only with other cached statements that were executed using the binary protocol. That is, for query cache purposes, prepared statements issued using the binary protocol are distinct from prepared statements issued using the text protocol (see [Section 13.5, “Prepared Statements”](#)).

A query cannot be cached if it uses any of the following functions:

- `BENCHMARK()`
- `CONNECTION_ID()`
- `CONVERT_TZ()`
- `CURDATE()`
- `CURRENT_DATE()`
- `CURRENT_TIME()`
- `CURRENT_TIMESTAMP()`
- `CURRENT_USER()`
- `CURTIME()`
- `DATABASE()`
- `ENCRYPT()` with one parameter
- `FOUND_ROWS()`
- `GET_LOCK()`

- `IS_FREE_LOCK()`
- `IS_USED_LOCK()`
- `LAST_INSERT_ID()`
- `LOAD_FILE()`
- `MASTER_POS_WAIT()`
- `NOW()`
- `RAND()`
- `RELEASE_ALL_LOCKS()`
- `RELEASE_LOCK()`
- `SLEEP()`
- `SYSDATE()`
- `UNIX_TIMESTAMP()` with no parameters
- `USER()`
- `UUID()`
- `UUID_SHORT()`

A query also is not cached under these conditions:

- It refers to user-defined functions (UDFs) or stored functions.
- It refers to user variables or local stored program variables.
- It refers to tables in the `mysql`, `INFORMATION_SCHEMA`, or `performance_schema` database.
- (*MySQL 5.5.23 and later.*) It refers to any partitioned tables.
- It is of any of the following forms:

```
SELECT ... LOCK IN SHARE MODE
SELECT ... FOR UPDATE
SELECT ... INTO OUTFILE ...
SELECT ... INTO DUMPFILE ...
SELECT * FROM ... WHERE autoincrement_col IS NULL
```

The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See the Connector/ODBC section of [Chapter 23, Connectors and APIs](#).

Statements within transactions that use `SERIALIZABLE` isolation level also cannot be cached because they use `LOCK IN SHARE MODE` locking.

- It uses `TEMPORARY` tables.
- It does not use any tables.
- It generates warnings.
- The user has a column-level privilege for any of the involved tables.

8.10.3.2 Query Cache SELECT Options

Two query cache-related options may be specified in `SELECT` statements:

- `SQL_CACHE`

The query result is cached if it is cacheable and the value of the `query_cache_type` system variable is `ON` or `DEMAND`.

- `SQL_NO_CACHE`

The server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result. (Due to a limitation in the parser, a space character must precede and follow the `SQL_NO_CACHE` keyword; a nonspace such as a newline causes the server to check the query cache to see whether the result is already cached.)

Examples:

```
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

8.10.3.3 Query Cache Configuration

The `have_query_cache` server system variable indicates whether the query cache is available:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_query_cache | YES |
+-----+-----+
```

When using a standard MySQL binary, this value is always `YES`, even if query caching is disabled.

Several other system variables control query cache operation. These can be set in an option file or on the command line when starting `mysqld`. The query cache system variables all have names that begin with `query_cache_`. They are described briefly in [Section 5.1.7, “Server System Variables”](#), with additional configuration information given here.

To set the size of the query cache, set the `query_cache_size` system variable. Setting it to 0 disables the query cache. The default size is 0, so the query cache is disabled by default.

To reduce overhead significantly, start the server with `query_cache_type=0` if you will not be using the query cache.

Note

When using the Windows Configuration Wizard to install or configure MySQL, the default value for `query_cache_size` will be configured automatically for you based on the different configuration types available. When using the Windows Configuration Wizard, the query cache may be enabled (that is, set to a nonzero value) due to the selected configuration. The query cache is also controlled by the setting of the `query_cache_type` variable. Check the values of these variables as set in your `my.ini` file after configuration has taken place.

When you set `query_cache_size` to a nonzero value, keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value too small, you'll get a warning, as in this example:

```
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1282
Message: Query cache failed to set size 39936;
new query cache size is 0
```

```
mysql> SET GLOBAL query_cache_size = 41984;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| query_cache_size | 41984 |
+-----+-----+
```

For the query cache to actually be able to hold any query results, its size must be set larger:

```
mysql> SET GLOBAL query_cache_size = 1000000;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| query_cache_size | 999424 |
+-----+-----+
1 row in set (0.00 sec)
```

The `query_cache_size` value is aligned to the nearest 1024 byte block. The value reported may therefore be different from the value that you assign.

If the query cache size is greater than 0, the `query_cache_type` variable influences how it works. This variable can be set to the following values:

- A value of `0` or `OFF` prevents caching or retrieval of cached results.
- A value of `1` or `ON` enables caching except of those statements that begin with `SELECT SQL_NO_CACHE`.
- A value of `2` or `DEMAND` causes caching of only those statements that begin with `SELECT SQL_CACHE`.

If `query_cache_size` is 0, you should also set `query_cache_type` variable to 0. In this case, the server does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

Setting the `GLOBAL query_cache_type` value determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the `SESSION query_cache_type` value. For example, a client can disable use of the query cache for its own queries like this:

```
mysql> SET SESSION query_cache_type = OFF;
```

If you set `query_cache_type` at server startup (rather than at runtime with a `SET` statement), only the numeric values are permitted.

To control the maximum size of individual query results that can be cached, set the `query_cache_limit` system variable. The default value is 1MB.

Be careful not to set the size of the cache too large. Due to the need for threads to lock the cache during updates, you may see lock contention issues with a very large cache.

Note

You can set the maximum size that can be specified for the query cache at runtime with the `SET` statement by using the `--maximum-query_cache_size=32M` option on the command line or in the configuration file.

When a query is to be cached, its result (the data sent to the client) is stored in the query cache during result retrieval. Therefore the data usually is not handled in one big chunk. The query cache

allocates blocks for storing this data on demand, so when one block is filled, a new block is allocated. Because memory allocation operation is costly (timewise), the query cache allocates blocks with a minimum size given by the `query_cache_min_res_unit` system variable. When a query is executed, the last result block is trimmed to the actual data size so that unused memory is freed. Depending on the types of queries your server executes, you might find it helpful to tune the value of `query_cache_min_res_unit`:

- The default value of `query_cache_min_res_unit` is 4KB. This should be adequate for most cases.
- If you have a lot of queries with small results, the default block size may lead to memory fragmentation, as indicated by a large number of free blocks. Fragmentation can force the query cache to prune (delete) queries from the cache due to lack of memory. In this case, decrease the value of `query_cache_min_res_unit`. The number of free blocks and queries removed due to pruning are given by the values of the `Qcache_free_blocks` and `Qcache_lowmem_prunes` status variables.
- If most of your queries have large results (check the `Qcache_total_blocks` and `Qcache_queries_in_cache` status variables), you can increase performance by increasing `query_cache_min_res_unit`. However, be careful to not make it too large (see the previous item).

8.10.3.4 Query Cache Status and Maintenance

To check whether the query cache is present in your MySQL server, use the following statement:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_query_cache | YES |
+-----+-----+
```

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The `RESET QUERY CACHE` statement removes all query results from the query cache. The `FLUSH TABLES` statement also does this.

To monitor query cache performance, use `SHOW STATUS` to view the cache status variables:

```
mysql> SHOW STATUS LIKE 'Qcache%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Qcache_free_blocks | 36 |
| Qcache_free_memory | 138488 |
| Qcache_hits | 79570 |
| Qcache_inserts | 27087 |
| Qcache_lowmem_prunes | 3114 |
| Qcache_not_cached | 22989 |
| Qcache_queries_in_cache | 415 |
| Qcache_total_blocks | 912 |
+-----+-----+
```

Descriptions of each of these variables are given in [Section 5.1.9, “Server Status Variables”](#). Some uses for them are described here.

The total number of `SELECT` queries is given by this formula:

```
Com_select
+ Qcache_hits
+ queries with errors found by parser
```

The `Com_select` value is given by this formula:

```
Qcache_inserts
+ Qcache_not_cached
+ queries with errors found during the column-privileges check
```

The query cache uses variable-length blocks, so `Qcache_total_blocks` and `Qcache_free_blocks` may indicate query cache memory fragmentation. After `FLUSH QUERY CACHE`, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one table block needs to be allocated.

The information provided by the `Qcache_lowmem_prunes` status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in [Section 8.10.3.3, “Query Cache Configuration”](#).

8.11 Optimizing Locking Operations

When your database is busy with multiple sessions reading and writing data, the mechanism that controls access to data files and memory areas can become a consideration for performance tuning. Otherwise, sessions can spend time waiting for access to resources when they could be running concurrently.

MySQL manages contention for table contents using locking:

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See [Section 8.11.1, “Internal Locking Methods”](#).
- External locking occurs when the server and other programs lock `MyISAM` table files to coordinate among themselves which program can access the tables at which time. See [Section 8.11.5, “External Locking”](#).

8.11.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. For locking performed on MySQL files by other programs, see [Section 8.11.5, “External Locking”](#).

- [Row-Level Locking](#)
- [Table-Level Locking](#)
- [Choosing the Type of Locking](#)

Row-Level Locking

MySQL uses [row-level locking](#) for `InnoDB` tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications.

To avoid [deadlocks](#) when performing multiple concurrent write operations on a single `InnoDB` table, acquire necessary locks at the start of the transaction by issuing a `SELECT ... FOR UPDATE` statement for each group of rows expected to be modified, even if the data change statements come later in the transaction. If transactions modify or lock more than one table, issue the applicable statements in the same order within each transaction. Deadlocks affect performance rather than representing a serious error, because `InnoDB` automatically [detects](#) deadlock conditions and rolls back one of the affected transactions.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows.
- Fewer changes for rollbacks.
- Possible to lock a single row for a long time.

Table-Level Locking

MySQL uses [table-level locking](#) for `MyISAM`, `MEMORY`, and `MERGE` tables, permitting only one session to update those tables at a time. This locking level makes these storage engines more suitable for read-only, read-mostly, or single-user applications.

These storage engines avoid [deadlocks](#) by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order. The tradeoff is that this strategy reduces concurrency; other sessions that want to modify the table must wait until the current data change statement finishes.

Advantages of table-level locking:

- Relatively little memory required (row locking requires memory per row or group of rows locked)
- Fast when used on a large part of the table because only a single lock is involved.
- Fast if you often do `GROUP BY` operations on a large part of the data or must scan the entire table frequently.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even when there is heavy `SELECT` activity for the table. However, if there are many updates for a table, `SELECT` statements wait until there are no more updates.

For information on altering the priority of reads and writes, see [Section 8.11.2, “Table Locking Issues”](#).

You can analyze the table lock contention on your system by checking the `Table_locks_immediate` and `Table_locks_waited` status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Table_locks_immediate | 1151552 |
| Table_locks_waited | 15324 |
+-----+-----+
```

The `MyISAM` storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a `MyISAM` table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent `INSERT` and `SELECT` statements for a `MyISAM` table without locks. That is, you can insert rows into a `MyISAM` table at the same time other clients are reading from it. Holes can result from rows having been deleted from

or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data. To control this behavior, use the `concurrent_insert` system variable. See [Section 8.11.3, “Concurrent Inserts”](#).

If you acquire a table lock explicitly with `LOCK TABLES`, you can request a `READ LOCAL` lock rather than a `READ` lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many `INSERT` and `SELECT` operations on a table `t1` when concurrent inserts are not possible, you can insert rows into a temporary table `temp_t1` and update the real table with the rows from the temporary table:

```
mysql> LOCK TABLES t1 WRITE, temp_t1 WRITE;
mysql> INSERT INTO t1 SELECT * FROM temp_t1;
mysql> DELETE FROM temp_t1;
mysql> UNLOCK TABLES;
```

Choosing the Type of Locking

Generally, table locks are superior to row-level locks in the following cases:

- Most statements for the table are reads.
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

```
UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
DELETE FROM tbl_name WHERE unique_key_col=key_value;
```

- `SELECT` combined with concurrent `INSERT` statements, and very few `UPDATE` or `DELETE` statements.
- Many scans or `GROUP BY` operations on the entire table without any writers.

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”
- Copy on demand is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.
- Instead of using row-level locks, you can employ application-level locks, such as those provided by `GET_LOCK()` and `RELEASE_LOCK()` in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See [Section 12.14, “Locking Functions”](#).

8.11.2 Table Locking Issues

`InnoDB` tables use row-level locking so that multiple sessions and applications can read from and write to the same table simultaneously, without making each other wait or producing inconsistent results. For this storage engine, avoid using the `LOCK TABLES` statement, because it does not offer any extra protection, but instead reduces concurrency. The automatic row-level locking makes these tables suitable for your busiest databases with your most important data, while also simplifying application logic since you do not need to lock and unlock tables. Consequently, the `InnoDB` storage engine is the default in MySQL 5.5 and higher.

MySQL uses table locking (instead of page, row, or column locking) for all storage engines except `InnoDB` and `NDB`. The locking operations themselves do not have much overhead. But because

only one session can write to a table at any one time, for best performance with these other storage engines, use them primarily for tables that are queried often and rarely inserted into or updated.

- [Performance Considerations Favoring InnoDB](#)
- [Workarounds for Locking Performance Issues](#)

Performance Considerations Favoring InnoDB

When choosing whether to create a table using `InnoDB` or a different storage engine, keep in mind the following disadvantages of table locking:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access, meaning it might have to wait for other sessions to finish with the table first. During the update, all other sessions that want to access this particular table must wait until the update is done.
- Table locking causes problems when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.
- A `SELECT` statement that takes a long time to run prevents other sessions from updating the table in the meantime, making the other sessions appear slow or unresponsive. While a session is waiting to get exclusive access to the table for updates, other sessions that issue `SELECT` statements will queue up behind it, reducing concurrency even for read-only sessions.

Workarounds for Locking Performance Issues

The following items describe some ways to avoid or reduce contention caused by table locking:

- Consider switching the table to the `InnoDB` storage engine, either using `CREATE TABLE ... ENGINE=INNODB` during setup, or using `ALTER TABLE ... ENGINE=INNODB` for an existing table. See [Chapter 14, The InnoDB Storage Engine](#) for more details about this storage engine.
- Optimize `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.
- Start `mysqld` with `--low-priority-updates`. For storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`), this gives all statements that update (modify) a table lower priority than `SELECT` statements. In this case, the second `SELECT` statement in the preceding scenario would execute before the `UPDATE` statement, and would not wait for the first `SELECT` to finish.
- To specify that all updates issued in a specific connection should be done with low priority, set the `low_priority_updates` server system variable equal to 1.
- To give a specific `INSERT`, `UPDATE`, or `DELETE` statement lower priority, use the `LOW_PRIORITY` attribute.
- To give a specific `SELECT` statement higher priority, use the `HIGH_PRIORITY` attribute. See [Section 13.2.9, “SELECT Statement”](#).
- Start `mysqld` with a low value for the `max_write_lock_count` system variable to force MySQL to temporarily elevate the priority of all `SELECT` statements that are waiting for a table after a specific number of inserts to the table occur. This permits `READ` locks after a certain number of `WRITE` locks.
- If you have problems with `INSERT` combined with `SELECT`, consider switching to `MyISAM` tables, which support concurrent `SELECT` and `INSERT` statements. (See [Section 8.11.3, “Concurrent Inserts”](#).)
- If you mix inserts and deletes on the same table, `INSERT DELAYED` may be of great help. See [Section 13.2.5.3, “INSERT DELAYED Statement”](#).

- If you have problems with mixed `SELECT` and `DELETE` statements, the `LIMIT` option to `DELETE` may help. See [Section 13.2.2, “DELETE Statement”](#).
- Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See [Section 13.2.9, “SELECT Statement”](#).
- Splitting table contents into separate tables may help, by allowing queries to run against columns in one table, while updates are confined to columns in a different table.
- You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

8.11.3 Concurrent Inserts

The `MyISAM` storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a `MyISAM` table has no holes in the data file (deleted rows in the middle), an `INSERT` statement can be executed to add rows to the end of the table at the same time that `SELECT` statements are reading rows from the table. If there are multiple `INSERT` statements, they are queued and performed in sequence, concurrently with the `SELECT` statements. The results of a concurrent `INSERT` may not be visible immediately.

The `concurrent_insert` system variable can be set to modify the concurrent-insert processing. By default, the variable is set to `AUTO` (or 1) and concurrent inserts are handled as just described. If `concurrent_insert` is set to `NEVER` (or 0), concurrent inserts are disabled. If the variable is set to `ALWAYS` (or 2), concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the `concurrent_insert` system variable.

Under circumstances where concurrent inserts can be used, there is seldom any need to use the `DELAYED` modifier for `INSERT` statements. See [Section 13.2.5.3, “INSERT DELAYED Statement”](#).

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See [Section 5.4.4, “The Binary Log”](#). In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With `LOAD DATA`, if you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while `LOAD DATA` is executing. Use of the `CONCURRENT` option affects the performance of `LOAD DATA` a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.

For `LOCK TABLE`, the difference between `READ LOCAL` and `READ` is that `READ LOCAL` permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

8.11.4 Metadata Locking

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies not just to tables, but also to schemas and stored programs (procedures, functions, triggers, and scheduled events).

Metadata locking does involve some overhead, which increases as query volume increases. Metadata contention increases the more that multiple queries attempt to access the same objects.

Metadata locking is not a replacement for the table definition cache, and its mutexes and locks differ from the `LOCK_open` mutex. The following discussion provides some information about how metadata locking works.

- [Metadata Lock Acquisition](#)
- [Metadata Lock Release](#)

Metadata Lock Acquisition

If there are multiple waiters for a given lock, the highest-priority lock request is satisfied first, with an exception related to the `max_write_lock_count` system variable. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

Statements acquire metadata locks one by one, not simultaneously, and perform deadlock detection in the process.

DML statements normally acquire locks in the order in which tables are mentioned in the statement.

DDL statements, `LOCK TABLES`, and other similar statements try to reduce the number of possible deadlocks between concurrent DDL statements by acquiring locks on explicitly named tables in name order. Locks might be acquired in a different order for implicitly used tables (such as tables in foreign key relationships that also must be locked).

For example, `RENAME TABLE` is a DDL statement that acquires locks in name order:

- This `RENAME TABLE` statement renames `tbla` to something else, and renames `tblc` to `tbla`:

```
RENAME TABLE tbla TO tbld, tblc TO tbla;
```

The statement acquires metadata locks, in order, on `tbla`, `tblc`, and `tbld` (because `tbld` follows `tblc` in name order):

- This slightly different statement also renames `tbla` to something else, and renames `tblc` to `tbla`:

```
RENAME TABLE tbla TO tblb, tblc TO tbla;
```

In this case, the statement acquires metadata locks, in order, on `tbla`, `tblb`, and `tblc` (because `tblb` precedes `tblc` in name order):

Both statements acquire locks on `tbla` and `tblc`, in that order, but differ in whether the lock on the remaining table name is acquired before or after `tblc`.

Metadata lock acquisition order can make a difference in operation outcome when multiple transactions execute concurrently, as the following example illustrates.

Begin with two tables `x` and `x_new` that have identical structure. Three clients issue statements that involve these tables:

Client 1:

```
LOCK TABLE x WRITE, x_new WRITE;
```

The statement requests and acquires write locks in name order on `x` and `x_new`.

Client 2:

```
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.

Client 3:

```
RENAME TABLE x TO x_old, x_new TO x;
```

The statement requests exclusive locks in name order on `x`, `x_new`, and `x_old`, but blocks waiting for the lock on `x`.

Client 1:

```
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `x_new`. The exclusive lock request for `x` by Client 3 has higher priority than the write lock request by Client 2, so Client 3 acquires its lock on `x`, then also on `x_new` and `x_old`, performs the renaming, and releases its locks. Client 2 then acquires its lock on `x`, performs the insert, and releases its lock.

Lock acquisition order results in the `RENAME TABLE` executing before the `INSERT`. The `x` into which the insert occurs is the table that was named `x_new` when Client 2 issued the insert and was renamed to `x` by Client 3:

```
mysql> SELECT * FROM x;
+-----+
| i     |
+-----+
|     1 |
+-----+

mysql> SELECT * FROM x_old;
Empty set (0.01 sec)
```

Now begin instead with tables named `x` and `new_x` that have identical structure. Again, three clients issue statements that involve these tables:

Client 1:

```
LOCK TABLE x WRITE, new_x WRITE;
```

The statement requests and acquires write locks in name order on `new_x` and `x`.

Client 2:

```
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.

Client 3:

```
RENAME TABLE x TO old_x, new_x TO x;
```

The statement requests exclusive locks in name order on `new_x`, `old_x`, and `x`, but blocks waiting for the lock on `new_x`.

Client 1:

```
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `new_x`. For `x`, the only pending request is by Client 2, so Client 2 acquires its lock, performs the insert, and releases the lock. For `new_x`, the only pending request is by Client 3, which is permitted to acquire that lock (and also the lock on `old_x`). The rename operation still blocks for the lock on `x` until the Client 2 insert finishes and releases its lock. Then Client 3 acquires the lock on `x`, performs the rename, and releases its lock.

In this case, lock acquisition order results in the `INSERT` executing before the `RENAME TABLE`. The `x` into which the insert occurs is the original `x`, now renamed to `old_x` by the rename operation:

```
mysql> SELECT * FROM x;
Empty set (0.01 sec)

mysql> SELECT * FROM old_x;
+-----+
| i     |
```

```
+-----+
|      1      |
+-----+
```

If order of lock acquisition in concurrent statements makes a difference to an application in operation outcome, as in the preceding example, you may be able to adjust the table names to affect the order of lock acquisition.

Metadata Lock Release

To ensure transaction serializability, the server must not permit one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted explicitly or implicitly started transaction in another session. The server achieves this by acquiring metadata locks on tables used within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table's structure. This locking approach has the implication that a table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the transaction ends.

This principle applies not only to transactional tables, but also to nontransactional tables. Suppose that a session begins a transaction that uses transactional table `t` and nontransactional table `nt` as follows:

```
START TRANSACTION;
SELECT * FROM t;
SELECT * FROM nt;
```

The server holds metadata locks on both `t` and `nt` until the transaction ends. If another session attempts a DDL or write lock operation on either table, it blocks until metadata lock release at transaction end. For example, a second session blocks if it attempts any of these operations:

```
DROP TABLE t;
ALTER TABLE t ...;
DROP TABLE nt;
ALTER TABLE nt ...;
LOCK TABLE t ... WRITE;
```

If the server acquires metadata locks for a statement that is syntactically valid but fails during execution, it does not release the locks early. Lock release is still deferred to the end of the transaction because the failed statement is written to the binary log and the locks protect log consistency.

In autocommit mode, each statement is in effect a complete transaction, so metadata locks acquired for the statement are held only to the end of the statement.

Metadata locks acquired during a `PREPARE` statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

8.11.5 External Locking

External locking is the use of file system locking to manage contention for `MyISAM` database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.
- If you use `myisamchk` to perform table maintenance operations on `MyISAM` tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with `myisamchk` for access to the tables. The same is true for use of `myisampack` to pack `MyISAM` tables.

If the server is run with external locking enabled, you can use `myisamchk` at any time for read operations such as checking tables. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` for write operations such as repairing or optimizing tables, or if you use `myisampack` to pack tables, you *must* always ensure that the `mysqld` server is not using the table. If you do not stop `mysqld`, at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as `myisamchk` need to modify tables while the server is running. If you only *read* tables with other programs, external locking is not required, although `myisamchk` might report warnings if the server changes tables while `myisamchk` is reading them.

With external locking disabled, to use `myisamchk`, you must either stop the server while `myisamchk` executes or else lock and flush the tables before running `myisamchk`. (See [Section 8.12.1, “System Factors”](#).) To avoid this requirement, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables.

For `mysqld`, external locking is controlled by the value of the `skip_external_locking` system variable. When this variable is enabled, external locking is disabled, and vice versa. External locking is disabled by default.

Use of external locking can be controlled at server startup by using the `--external-locking` or `--skip-external-locking` option.

If you do use external locking option to enable updates to `MyISAM` tables from many MySQL processes, you must ensure that the following conditions are satisfied:

- Do not use the query cache for queries that use tables that are updated by another process.
- Do not start the server with the `delay_key_write` system variable set to `ALL` or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy these conditions is to always use `--external-locking` together with `--delay-key-write=OFF` and `--query-cache-size=0`. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

8.12 Optimizing the MySQL Server

This section discusses optimization techniques for the database server, primarily dealing with system configuration rather than tuning SQL statements. The information in this section is appropriate for DBAs who want to ensure performance and scalability across the servers they manage; for developers constructing installation scripts that include setting up the database; and people running MySQL themselves for development, testing, and so on who want to maximize their own productivity.

8.12.1 System Factors

Some system-level factors can affect performance in a major way:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.
- Avoid external locking for `MyISAM` tables. The default is for external locking to be disabled. The `--external-locking` and `--skip-external-locking` options explicitly enable and disable external locking.

Disabling external locking does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run `myisamchk`. On some systems it is mandatory to disable external locking because it does not work, anyway.

The only case in which you cannot disable external locking is when you run multiple MySQL servers (not clients) on the same data, or if you run `myisamchk` to check (not repair) a table without telling the server to flush and lock the tables first. Note that using multiple MySQL servers to access the same data concurrently is generally *not* recommended, except when using NDB Cluster.

The `LOCK TABLES` and `UNLOCK TABLES` statements use internal locking, so you can use them even if external locking is disabled.

8.12.2 Optimizing Disk I/O

This section describes ways to configure storage devices when you can devote more and faster storage hardware to the database server. For information about optimizing an `InnoDB` configuration to improve I/O performance, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.
- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:
 - Using symbolic links

This means that, for `MyISAM` tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See [Section 8.12.3, “Using Symbolic Links”](#).

Symbolic links are not supported for use with `InnoDB` tables. However, it is possible to place `InnoDB` data and log files on different physical disks. For more information, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- Striping

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the N -th block on the $(N \text{ MOD } \textit{number_of_disks})$ disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See [Section 8.13.3, “Using Your Own Benchmarks”](#).

The speed difference for striping is *very* dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

- For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need $2 \times N$ drives to hold N drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.
- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID N disk. RAID N can be a problem if you have many writes, due to the time required to update the parity bits.

- You can also set the parameters for the file system that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

Using NFS with MySQL

Caution is advised when considering using NFS with MySQL. Potential issues, which vary by operating system and NFS version, include:

- MySQL data and log files placed on NFS volumes becoming locked and unavailable for use. Locking issues may occur in cases where multiple instances of MySQL access the same data directory or where MySQL is shut down improperly, due to a power outage, for example. NFS version 4 addresses underlying locking issues with the introduction of advisory and lease-based locking. However, sharing a data directory among MySQL instances is not recommended.
- Data inconsistencies introduced due to messages received out of order or lost network traffic. To avoid this issue, use TCP with `hard` and `intr` mount options.
- Maximum file size limitations. NFS Version 2 clients can only access the lowest 2GB of a file (signed 32 bit offset). NFS Version 3 clients support larger files (up to 64 bit offsets). The maximum supported file size also depends on the local file system of the NFS server.

Using NFS within a professional SAN environment or other storage system tends to offer greater reliability than using NFS outside of such an environment. However, NFS within a SAN environment may be slower than directly attached or bus-attached non-rotational storage.

If you choose to use NFS, NFS Version 4 or later is recommended, as is testing your NFS setup thoroughly before deploying into a production environment.

8.12.3 Using Symbolic Links

You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink `MyISAM` tables only as a last resort.

To determine the location of your data directory, use this statement:

```
SHOW VARIABLES LIKE 'datadir';
```

8.12.3.1 Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a soft link to it from the MySQL data directory.

```
shell> mkdir /dr1/databases/test
shell> ln -s /dr1/databases/test /path/to/datadir
```

MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```
shell> cd /path/to/datadir
shell> ln -s db1 db2
```

The result is that, for any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

8.12.3.2 Using Symbolic Links for MyISAM Tables on Unix

Symlinks are fully supported only for [MyISAM](#) tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links.

Do not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). To determine whether your system supports symbolic links, check the value of the `have_symlink` system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

The handling of symbolic links for [MyISAM](#) tables works as follows:

- In the data directory, you always have the table format (`.frm`) file, the data (`.MYD`) file, and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The format file cannot.
- You can symlink the data file and the index file independently to different directories.
- To instruct a running MySQL server to perform the symlinking, use the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See [Section 13.1.17, “CREATE TABLE Statement”](#). Alternatively, if `mysqld` is not running, symlinking can be accomplished manually using `ln -s` from the command line.

Note

The path used with either or both of the `DATA DIRECTORY` and `INDEX DIRECTORY` options may not include the MySQL `data` directory. (Bug #32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the `ALTER TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.

Note

When you drop a table that is using symlinks, *both the symlink and the file to which the symlink points are dropped*. This is an extremely good reason *not* to run `mysqld` as the `root` operating system user or permit operating system users to have write access to MySQL database directories.

- If you rename a table with `ALTER TABLE ... RENAME` or `RENAME TABLE` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you use `ALTER TABLE ... RENAME` or `RENAME TABLE` to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you are not using symlinks, start `mysqld` with the `--skip-symbolic-links` option to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.

- As indicated previously, only the data and index files can be symbolic links. The `.frm` file must *never* be a symbolic link. Attempting to do this (for example, to make one table name a synonym for another) produces incorrect results. Suppose that you have a database `db1` under the MySQL data directory, a table `tbl1` in this database, and in the `db1` directory you make a symlink `tbl2` that points to `tbl1`:

```
shell> cd /path/to/datadir/db1
shell> ln -s tbl1.frm tbl2.frm
shell> ln -s tbl1.MYD tbl2.MYD
shell> ln -s tbl1.MYI tbl2.MYI
```

Problems result if one thread reads `db1.tbl1` and another thread updates `db1.tbl2`:

- The query cache is “fooled” (it has no way of knowing that `tbl1` has not been updated, so it returns outdated results).
- `ALTER` statements on `tbl2` fail.

8.12.3.3 Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named `mydb` at `D:\data\mydb`. To do this, create a symbolic link in the MySQL data directory that points to `D:\data\mydb`. However, before creating the symbolic link, make sure that the `D:\data\mydb` directory exists by creating it if necessary. If you already have a database directory named `mydb` in the data directory, move it to `D:\data`. Otherwise, the symbolic link will be ineffective. To avoid problems, make sure that the server is not running when you move the database directory.

The procedure for creating the database symbolic link depends on your version of Windows.

On Windows, you can create a symlink using the `mklink` command. This command requires administrative privileges.

1. Change location into the data directory:

```
C:\> cd \path\to\datadir
```

2. In the data directory, create a symlink named `mydb` that points to the location of the database directory:

```
C:\> mklink /d mydb D:\data\mydb
```

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

Alternatively, on any version of Windows supported by MySQL, you can create a symbolic link to a MySQL database by creating a `.sym` file in the data directory that contains the path to the destination directory. The file should be named `db_name.sym`, where `db_name` is the database name.

Support for database symbolic links on Windows using `.sym` files is enabled by default. If you do not need `.sym` file symbolic links, you can disable support for them by starting `mysqld` with the `--skip-symbolic-links` option. To determine whether your system supports `.sym` file symbolic links, check the value of the `have_symlink` system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

To create a `.sym` file symlink, use this procedure:

1. Change location into the data directory:

```
C:\> cd \path\to\datadir
```

2. In the data directory, create a text file named `mydb.sym` that contains this path name: `D:\data\mydb\`

Note

The path name to the new database and tables should be absolute. If you specify a relative path, the location will be relative to the `mydb.sym` file.

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

The following limitations apply to the use of `.sym` files for database symbolic linking on Windows. These limitations do not apply for symlinks created using `mklink`.

- The symbolic link is not used if a directory with the same name as the database exists in the MySQL data directory.
- The `--innodb_file_per_table` option cannot be used.
- If you run `mysqld` as a service, you cannot use a mapped drive to a remote server as the destination of the symbolic link. As a workaround, you can use the full path (`\\servername\path\`).

8.12.4 Optimizing Memory Use

8.12.4.1 How MySQL Uses Memory

MySQL allocates buffers and caches to improve performance of database operations. You can improve MySQL performance by increasing the values of certain cache and buffer-related system variables. You can also modify these variables to run MySQL on systems with limited memory.

The following list describes some of the ways that MySQL uses memory. Where applicable, relevant system variables are referenced. Some items are storage engine or feature specific.

- The `InnoDB` buffer pool is a memory area that holds cached `InnoDB` data for tables, indexes, and other auxiliary buffers. For efficiency of high-volume read operations, the buffer pool is divided into `pages` that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the `LRU` algorithm. For more information, see [Section 14.8.1, “Buffer Pool”](#).

The size of the buffer pool is important for system performance:

- `InnoDB` allocates memory for the entire buffer pool at server startup, using `malloc()` operations. The `innodb_buffer_pool_size` system variable defines the buffer pool size. Typically, a recommended `innodb_buffer_pool_size` value is 50 to 75 percent of system memory. For more information, see [Configuring InnoDB Buffer Pool Size](#).
- On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple `buffer pool instances`. The `innodb_buffer_pool_instances` system variable defines the number of buffer pool instances.
- A buffer pool that is too small may cause excessive churning as pages are flushed from the buffer pool only to be required again a short time later.
- A buffer pool that is too large may cause swapping due to competition for memory.
- All threads share the `MyISAM` key buffer. The `key_buffer_size` system variable determines its size.

For each `MyISAM` table the server opens, the index file is opened once; the data file is opened once for each concurrently running thread that accesses the table. For each concurrent thread, a table structure, column structures for each column, and a buffer of size $3 * N$ are allocated (where N is the maximum row length, not counting `BLOB` columns). A `BLOB` column requires five to eight bytes

plus the length of the `BLOB` data. The `MyISAM` storage engine maintains one extra row buffer for internal use.

- The `myisam_use_mmap` system variable can be set to 1 to enable memory-mapping for all `MyISAM` tables.
- If an internal in-memory temporary table becomes too large (as determined using the `tmp_table_size` and `max_heap_table_size` system variables), MySQL automatically converts the table from in-memory to on-disk format. On-disk temporary tables use the `MyISAM` storage engine. You can increase the permissible temporary table size as described in [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

For `MEMORY` tables explicitly created with `CREATE TABLE`, only the `max_heap_table_size` system variable determines how large a table can grow, and there is no conversion to on-disk format.

- The [MySQL Performance Schema](#) is a feature for monitoring MySQL server execution at a low level. For performance reasons, fixed memory buffers for Performance Schema are allocated at server startup and do not change in size while the server is running.
- Each thread that the server uses to manage client connections requires some thread-specific space. The following list indicates these and which system variables control their size:
 - A stack (`thread_stack`)
 - A connection buffer (`net_buffer_length`)
 - A result buffer (`net_buffer_length`)

The connection buffer and result buffer each begin with a size equal to `net_buffer_length` bytes, but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

- All threads share the same base memory.
- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.
- Each request that performs a sequential scan of a table allocates a *read buffer*. The `read_buffer_size` system variable determines the buffer size.
- When reading rows in an arbitrary sequence (for example, following a sort), a *random-read buffer* may be allocated to avoid disk seeks. The `read_rnd_buffer_size` system variable determines the buffer size.
- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain `BLOB` columns are stored on disk.
- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See [Section B.4.3.5, “Where MySQL Stores Temporary Files”](#).
- Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, thus avoiding the normal slow memory allocation and freeing. Memory is allocated only for unexpectedly large strings.
- For each table having `BLOB` columns, a buffer is enlarged dynamically to read in larger `BLOB` values. If you scan a table, the buffer grows as large as the largest `BLOB` value.
- MySQL requires memory and descriptors for the table cache. Handler structures for all in-use tables are saved in the table cache and managed as “First In, First Out” (FIFO). The `table_open_cache`

system variable defines the initial table cache size; see [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#).

MySQL also requires memory for the table definition cache. The `table_definition_cache` system variable defines the number of table definitions (from `.frm` files) that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up the opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the table cache.

- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.
- The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in cached memory use unless it is freed with `FLUSH PRIVILEGES`.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. To verify this, check available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

8.12.4.2 Enabling Large Page Support

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

MySQL also supports the Linux implementation of large page support (which is called HugeTLB in Linux).

Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTLB API is documented in the [Documentation/vm/hugetlbpage.txt](#) file of your Linux sources.

The kernel for some recent systems such as Red Hat Enterprise Linux appear to have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      0
HugePages_Free:      0
HugePages_Rsvd:      0
HugePages_Surp:      0
Hugepagesize:       4096 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the [hugetlbpage.txt](#) file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following commands. Normally, you put these in an `rc` file or equivalent startup file that is executed during the system boot sequence, so that the commands execute each time the system starts. The commands should execute early in the boot sequence, before the MySQL server starts. Be sure to change the allocation numbers and the group number as appropriate for your system.

```
# Set the number of pages to be used.
# Each page is normally 2MB, so a value of 20 = 40MB.
# This command actually allocates memory, so this much
# memory must be available.
echo 20 > /proc/sys/vm/nr_hugepages

# Set the group number that is permitted to access this
# memory (102 in this case). The mysql user must be a
# member of this group.
echo 102 > /proc/sys/vm/hugetlb_shm_group

# Increase the amount of shmem permitted per segment
# (12G in this case).
echo 1560281088 > /proc/sys/kernel/shmmax

# Increase total amount of shared memory. The value
# is the number of pages. At 4KB/page, 4194304 = 16GB.
echo 4194304 > /proc/sys/kernel/shmall
```

For MySQL usage, you normally want the value of `shmmax` to be close to the value of `shmall`.

To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some nonzero values:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:      20
HugePages_Rsvd:       0
HugePages_Surp:       0
Hugepagesize:        4096 kB
```

The final step to make use of the `hugetlb_shm_group` is to give the `mysql` user an “unlimited” value for the memlock limit. This can be done either by editing `/etc/security/limits.conf` or by adding the following command to your `mysqld_safe` script:

```
ulimit -l unlimited
```

Adding the `ulimit` command to `mysqld_safe` causes the `root` user to set the memlock limit to `unlimited` before switching to the `mysql` user. (This assumes that `mysqld_safe` is started by `root`.)

Large page support in MySQL is disabled by default. To enable it, start the server with the `--large-pages` option. For example, you can use the following lines in the server `my.cnf` file:

```
[mysqld]
large-pages
```

With this option, `InnoDB` uses large pages automatically for its buffer pool and additional memory pool. If `InnoDB` cannot do this, it falls back to use of traditional memory and writes a warning to the error log: `Warning: Using conventional memory pool`

To verify that large pages are being used, check `/proc/meminfo` again:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:      20
HugePages_Rsvd:       2
HugePages_Surp:       0
```

8.12.5 Optimizing Network Use

8.12.5.1 How MySQL Handles Client Connections

This section describes aspects of how the MySQL server manages client connections.

- [Network Interfaces and Connection Manager Threads](#)
- [Client Connection Thread Management](#)
- [Connection Volume Management](#)

Network Interfaces and Connection Manager Threads

The server is capable of listening for client connections on multiple network interfaces. Connection manager threads handle client connection requests on the network interfaces that the server listens to:

- On all platforms, one manager thread handles TCP/IP connection requests.
- On Unix, the same manager thread also handles Unix socket file connection requests.
- On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests.

The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

Client Connection Thread Management

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

As of MySQL 5.5.16, MySQL Enterprise Edition includes a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. It implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections. See [Section 5.5.3, “MySQL Enterprise Thread Pool”](#).

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See [Section 5.1.7, “Server System Variables”](#), and [Section 5.1.9, “Server Status Variables”](#).)

The `thread_cache_size` system variable determines the thread cache size. A value of 0 disables caching, which causes a thread to be set up for each new connection and disposed of when the connection terminates. To enable *N* inactive connection threads to be cached, set `thread_cache_size` to *N* at server startup or at runtime. A connection thread becomes inactive when the client connection with which it was associated terminates.

To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, check the `Threads_cached` and `Threads_created` status variables.

When the thread stack is too small, this limits the complexity of the SQL statements which the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of *N* bytes for each thread, start the server with `thread_stack`. set to *N* at server startup.

Connection Volume Management

To control the maximum number of clients the server permits to connect simultaneously, set the `max_connections` system variable at server startup or at runtime. It may be necessary to increase `max_connections` if more clients attempt to connect simultaneously than the server is configured to handle (see [Section B.4.2.7, “Too many connections”](#)).

`mysqld` actually permits `max_connections` + 1 client connections. The extra connection is reserved for use by accounts that have the `SUPER` privilege. By granting the privilege to administrators and not to normal users (who should not need it), an administrator who also has the `PROCESS` privilege can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See [Section 13.7.5.30, “SHOW PROCESSLIST Statement”](#).

The maximum number of connections MySQL supports (that is, the maximum value to which `max_connections` can be set) depends on several factors:

- The quality of the thread library on a given platform.
- The amount of RAM available.
- The amount of RAM is used for each connection.
- The workload from each connection.
- The desired response time.
- The number of file descriptors available.

Linux or Solaris should be able to support at least 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding.

Increasing the `max_connections` value increases the number of file descriptors that `mysqld` requires. If the required number of descriptors are not available, the server reduces the value of `max_connections`. For comments on file descriptor limits, see [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#).

Increasing the `open_files_limit` system variable may be necessary, which may also require raising the operating system limit on how many file descriptors can be used by MySQL. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so. See also [Section B.4.2.18, “File Not Found and Similar Errors”](#).

8.12.5.2 DNS Lookup Optimization and the Host Cache

The MySQL server maintains a host cache in memory that contains information about clients: IP address, host name, and error information.

Note

The server uses the host cache only for nonlocal TCP connections. It does not use the cache for TCP connections established using a loopback interface

address (for example, `127.0.0.1` or `::1`), or for connections established using a Unix socket file, named pipe, or shared memory.

- [Host Cache Operation](#)
- [Host Cache Configuration](#)

Host Cache Operation

The server uses the host cache for several purposes:

- By caching the results of IP-to-host name lookups, the server avoids doing a Domain Name System (DNS) lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.
- The cache contains information about errors that occur during the connection process. Some errors are considered “blocking.” If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The `max_connect_errors` system variable determines the permitted number of successive errors before blocking occurs (see [Section B.4.2.6](#), “Host 'host_name' is blocked”).

For each new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If so, the server refuses or continues to process the connection request depending on whether or not the host is blocked. If the host is not in the cache, the server attempts to resolve the host name. First, it resolves the IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same. The server stores information about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The server performs host name resolution using the `gethostbyaddr()` and `gethostbyname()` system calls.

To unblock blocked hosts, flush the host cache by executing a `FLUSH HOSTS` statement or `mysqladmin flush-hosts` command.

It is possible for a blocked host to become unblocked even without flushing the host cache if activity from other hosts has occurred since the last connection attempt from the blocked host. This can occur because the server discards the least recently used cache entry to make room for a new entry if the cache is full when a connection arrives from a client IP not in the cache. If the discarded entry is for a blocked host, that host becomes unblocked.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

Host Cache Configuration

The host cache is enabled by default. To disable it, start the server with the `--skip-host-cache` option. With the cache disabled, the server performs a DNS lookup every time a client connects.

To disable DNS host name lookups, start the server with the `skip_name_resolve` system variable enabled. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used. (A client may not be able to connect if no account exists that specifies the client IP address.)

If you have a very slow DNS and many hosts, you might be able to improve performance either by disabling DNS lookups by enabling `skip_name_resolve` or by increasing the `HOST_CACHE_SIZE` define (default value: 128) and recompiling the server

To disallow TCP/IP connections entirely, start the server with the `skip_networking` system variable enabled.

8.13 Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a “workload”) works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.
- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.
- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.
- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The two most important features to try with each workload are the [MySQL query cache](#), and the [adaptive hash index](#) for [InnoDB](#) tables.

This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

8.13.1 Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count, expr)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+-----+
| BENCHMARK(1000000,1+1) |
+-----+
|                          0 |
+-----+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

8.13.2 The MySQL Benchmark Suite

This benchmark suite is meant to tell any user what operations a given SQL implementation performs well or poorly. You can get a good idea for how the benchmarks work by looking at the code and results in the `sql-bench` directory in any MySQL source distribution.

To use the benchmark suite, the following requirements must be satisfied:

- The benchmark suite is provided with MySQL source distributions. You can either download a released distribution from <https://dev.mysql.com/downloads/>, or use the current development source tree. (See [Section 2.9.5, “Installing MySQL Using a Development Source Tree”](#).)
- The benchmark scripts are written in Perl and use the Perl DBI module to access database servers, so DBI must be installed. You also need the server-specific DBD drivers for each of the servers you

want to test. For example, to test MySQL, PostgreSQL, and DB2, you must have the `DBD::mysql`, `DBD::Pg`, and `DBD::DB2` modules installed. See [Section 2.13, “Perl Installation Notes”](#).

After you obtain a MySQL source distribution, you can find the benchmark suite located in its `sql-bench` directory. To run the benchmark tests, build MySQL, and then change location into the `sql-bench` directory and execute the `run-all-tests` script:

```
shell> cd sql-bench
shell> perl run-all-tests --server=server_name
```

`server_name` should be the name of one of the supported servers. To get a list of all options and supported servers, invoke this command:

```
shell> perl run-all-tests --help
```

The `crash-me` script also is located in the `sql-bench` directory. `crash-me` tries to determine what features a database system supports and what its capabilities and limitations are by actually running queries. For example, it determines:

- What data types are supported
- How many indexes are supported
- What functions are supported
- How big a query can be
- How big a `VARCHAR` column can be

For more information about benchmark results, visit <http://www.mysql.com/why-mysql/benchmarks/>.

8.13.3 Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

For examples of portable benchmark programs, look at those in the MySQL benchmark suite. See [Section 8.13.2, “The MySQL Benchmark Suite”](#). You can take any program from this suite and modify it for your own needs. By doing this, you can try different solutions to your problem and test which really is fastest for you.

Another free benchmark suite is the Open Source Database Benchmark, available at <http://osdb.sourceforge.net/>.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See [Section 4.5.7, “mysqlslap — Load Emulation Client”](#).
- You can also try benchmarking packages such as SysBench and DBT2, available at <https://launchpad.net/sysbench>, and <http://osldb.sourceforge.net/#dbt2>.

These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

8.13.4 Measuring Performance with performance_schema

You can query the tables in the `performance_schema` database to see real-time information about the performance characteristics of your server and the applications it is running. See [Chapter 22, MySQL Performance Schema](#) for details.

8.14 Examining Thread Information

As you monitor the performance of your MySQL server, examine the process list, which is the set of threads currently executing within the server. Process list information is available from these sources:

- The `SHOW [FULL] PROCESSLIST` statement: [Section 13.7.5.30, “SHOW PROCESSLIST Statement”](#)
- The `SHOW PROFILE` statement: [Section 13.7.5.32, “SHOW PROFILES Statement”](#)
- The `INFORMATION_SCHEMA PROCESSLIST` table: [Section 21.15, “The INFORMATION_SCHEMA PROCESSLIST Table”](#)
- The `mysqladmin processlist` command: [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)

You can always view information about your own threads. To view information about threads being executed for other accounts, you must have the `PROCESS` privilege.

Each process list entry contains several pieces of information:

- `Id` is the connection identifier for the client associated with the thread.
- `User` and `Host` indicate the account associated with the thread.
- `db` is the default database for the thread, or `NULL` if none is selected.
- `Command` and `State` indicate what the thread is doing.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- `Time` indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a thread running on a slave that is processing events from the master, the thread time is set to the time found in the events and thus reflects current time on the master and not the slave.
- `Info` contains the text of the statement being executed by the thread, or `NULL` if it is not executing one. By default, this value contains only the first 100 characters of the statement. To see the complete statements, use `SHOW FULL PROCESSLIST`.

The following sections list the possible `Command` values, and `State` values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

8.14.1 Thread Command Values

A thread can have any of the following `Command` values:

- `Binlog Dump`

This is a thread on a master server for sending binary log contents to a slave server.

- `Change user`

The thread is executing a change-user operation.

- `Close stmt`

The thread is closing a prepared statement.

- `Connect`

A replication slave is connected to its master.

- `Connect Out`

A replication slave is connecting to its master.

- `Create DB`

The thread is executing a create-database operation.

- `Daemon`

This thread is internal to the server, not a thread that services a client connection.

- `Debug`

The thread is generating debugging information.

- `Delayed insert`

The thread is a delayed-insert handler.

- `Drop DB`

The thread is executing a drop-database operation.

- `Error`

- `Execute`

The thread is executing a prepared statement.

- `Fetch`

The thread is fetching the results from executing a prepared statement.

- `Field List`

The thread is retrieving information for table columns.

- `Init DB`

The thread is selecting a default database.

- `Kill`

The thread is killing another thread.

- `Long Data`

The thread is retrieving long data in the result of executing a prepared statement.

- `Ping`

The thread is handling a server-ping request.

- `Prepare`
The thread is preparing a prepared statement.
- `Processlist`
The thread is producing information about server threads.
- `Query`
The thread is executing a statement.
- `Quit`
The thread is terminating.
- `Refresh`
The thread is flushing table, logs, or caches, or resetting status variable or replication server information.
- `Register Slave`
The thread is registering a slave server.
- `Reset stmt`
The thread is resetting a prepared statement.
- `Set option`
The thread is setting or resetting a client statement-execution option.
- `Shutdown`
The thread is shutting down the server.
- `Sleep`
The thread is waiting for the client to send a new statement to it.
- `Statistics`
The thread is producing server-status information.
- `Table Dump`
The thread is sending table contents to a slave server.
- `Time`
Unused.

8.14.2 General Thread States

The following list describes thread `State` values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- `After create`
This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

- `Analyzing`

The thread is calculating a `MyISAM` table key distributions (for example, for `ANALYZE TABLE`).

- `checking permissions`

The thread is checking whether the server has the required privileges to execute the statement.

- `Checking table`

The thread is performing a table check operation.

- `cleaning up`

The thread has processed one command and is preparing to free memory and reset certain state variables.

- `closing tables`

The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, verify that you do not have a full disk and that the disk is not in very heavy use.

- `converting HEAP to MyISAM`

The thread is converting an internal temporary table from a `MEMORY` table to an on-disk `MyISAM` table.

- `copy to tmp table`

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

- `Copying to group table`

If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- `Copying to tmp table`

The server is copying to a temporary table in memory.

- `Copying to tmp table on disk`

The server is copying to a temporary table on disk. The temporary result set has become too large (see [Section 8.4.4, "Internal Temporary Table Use in MySQL"](#)). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- `Creating index`

The thread is processing `ALTER TABLE ... ENABLE KEYS` for a `MyISAM` table.

- `Creating sort index`

The thread is processing a `SELECT` that is resolved using an internal temporary table.

- `creating table`

The thread is creating a table. This includes creation of temporary tables.

- `Creating tmp table`

The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation will be `Copying to tmp table on disk`.

- `deleting from main table`

The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- `deleting from reference tables`

The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- `discard_or_import_tablespace`

The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- `end`

This occurs at the end but before the cleanup of `ALTER TABLE`, `CREATE VIEW`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

- `executing`

The thread has begun executing a statement.

- `Execution of init_command`

The thread is executing statements in the value of the `init_command` system variable.

- `freeing items`

The thread has executed a command. Some freeing of items done during this state involves the query cache. This state is usually followed by `cleaning up`.

- `FULLTEXT initialization`

The server is preparing to perform a natural-language full-text search.

- `init`

This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log, the `InnoDB` log, and some query cache cleanup operations.

For the `end` state, the following operations could be happening:

- Removing query cache entries after data in a table is changed
- Writing an event to the binary log
- Freeing memory buffers, including for blobs

- `Killed`

Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- `logging slow query`

The thread is writing a statement to the slow-query log.

- `login`

The initial state for a connection thread until the client has been authenticated successfully.

- `manage keys`

The server is enabling or disabling a table index.

- `NULL`

This state is used for the `SHOW PROCESSLIST` state.

- `Opening tables, Opening table`

The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` value is large enough.

- `optimizing`

The server is performing initial optimizations for a query.

- `preparing`

This state occurs during query optimization.

- `Purging old relay logs`

The thread is removing unneeded relay log files.

- `query end`

This state occurs after processing a query but before the `freeing items` state.

- `Reading from net`

The server is reading a packet from the network.

- `Removing duplicates`

The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- `removing tmp table`

The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- `rename`

The thread is renaming a table.

- `rename result table`

The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- `Reopen tables`

The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- `Repair by sorting`

The repair code is using a sort to create indexes.

- `Repair done`

The thread has completed a multithreaded repair for a `MyISAM` table.

- `Repair with keycache`

The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- `Rolling back`

The thread is rolling back a transaction.

- `Saving state`

For `MyISAM` table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the `AUTO_INCREMENT` counter, and key distributions.

- `Searching rows for update`

The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- `Sending data`

The thread is reading and processing rows for a `SELECT` statement, and sending data to the client. Because operations occurring during this state tend to perform large amounts of disk access (reads), it is often the longest-running state over the lifetime of a given query.

- `setup`

The thread is beginning an `ALTER TABLE` operation.

- `Sorting for group`

The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

The thread is doing a sort to satisfy an `ORDER BY`.

- `Sorting index`

The thread is sorting index pages for more efficient access during a `MyISAM` table optimization operation.

- `Sorting result`

For a `SELECT` statement, this is similar to `Creating sort index`, but for nontemporary tables.

- `statistics`

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

- `System lock`

The thread has called `mysql_lock_tables()` and the thread state has not been updated since. This is a very general state that can occur for many reasons.

For example, the thread is going to request or is waiting for an internal or external system lock for the table. This can occur when `InnoDB` waits for a table-level lock during execution of `LOCK TABLES`. If this state is being caused by requests for external locks and you are not using multiple `mysqld` servers that are accessing the same `MyISAM` tables, you can disable external system locks with the `--skip-external-locking` option. However, external locking is disabled by default, so it is likely that this option will have no effect. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `update`

The thread is getting ready to start updating the table.

- `Updating`

The thread is searching for rows to update and is updating them.

- `updating main table`

The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- `updating reference tables`

The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- `User lock`

The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` call. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `User sleep`

The thread has invoked a `SLEEP()` call.

- `Waiting for commit lock`

A statement that causes an explicit or implicit commit is waiting for release of a read lock or `FLUSH TABLES WITH READ LOCK` is waiting for a commit lock.

- `Waiting for global read lock`

`FLUSH TABLES WITH READ LOCK` is waiting for a global read lock or the global `read_only` system variable is being set.

- `Waiting for tables`

The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting for table flush`

The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables, or the thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting for lock_type lock`

The server is waiting to acquire a `THR_LOCK` lock or a lock from the metadata locking subsystem, where `lock_type` indicates the type of lock.

This state indicates a wait for a `THR_LOCK`:

- `Waiting for table level lock`

These states indicate a wait for a metadata lock:

- `Waiting for event metadata lock`
- `Waiting for global metadata lock`
- `Waiting for global read lock`
- `Waiting for schema metadata lock`
- `Waiting for stored function metadata lock`
- `Waiting for stored procedure metadata lock`
- `Waiting for table metadata lock`
- `Waiting for trigger metadata lock`

For information about table lock indicators, see [Section 8.11.1, “Internal Locking Methods”](#). For information about metadata locking, see [Section 8.11.4, “Metadata Locking”](#).

- `Waiting on cond`

A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

- `Writing to net`

The server is writing a packet to the network.

8.14.3 Delayed-Insert Thread States

These thread states are associated with processing for `DELAYED` inserts (see [Section 13.2.5.3, “INSERT DELAYED Statement”](#)). Some states are associated with connection threads that process `INSERT DELAYED` statements from clients. Other states are associated with delayed-insert handler threads that insert the rows. There is a delayed-insert handler thread for each table for which `INSERT DELAYED` statements are issued.

States associated with a connection thread that processes an `INSERT DELAYED` statement from the client:

- `allocating local table`

The thread is preparing to feed rows to the delayed-insert handler thread.

- `Creating delayed handler`

The thread is creating a handler for `DELAYED` inserts.

- `got handler lock`

This occurs before the `allocating local table` state and after the `waiting for handler lock` state, when the connection thread gets access to the delayed-insert handler thread.

- `got old table`

This occurs after the `waiting for handler open` state. The delayed-insert handler thread has signaled that it has ended its initialization phase, which includes opening the table for delayed inserts.

- `storing row into queue`

The thread is adding a new row to the list of rows that the delayed-insert handler thread must insert.

- `waiting for delay_list`

This occurs during the initialization phase when the thread is trying to find the delayed-insert handler thread for the table, and before attempting to gain access to the list of delayed-insert threads.

- `waiting for handler insert`

An `INSERT DELAYED` handler has processed all pending inserts and is waiting for new ones.

- `waiting for handler lock`

This occurs before the `allocating local table` state when the connection thread waits for access to the delayed-insert handler thread.

- `waiting for handler open`

This occurs after the `Creating delayed handler` state and before the `got old table` state. The delayed-insert handler thread has just been started, and the connection thread is waiting for it to initialize.

States associated with a delayed-insert handler thread that inserts the rows:

- `insert`

The state that occurs just before inserting rows into the table.

- `reschedule`

After inserting a number of rows, the delayed-insert thread sleeps to let other threads do work.

- `upgrading lock`

A delayed-insert handler is trying to get a lock for the table to insert rows.

- `Waiting for INSERT`

A delayed-insert handler is waiting for a connection thread to add rows to the queue (see `storing row into queue`).

8.14.4 Query Cache Thread States

These thread states are associated with the query cache (see [Section 8.10.3, “The MySQL Query Cache”](#)).

- `checking privileges on cached query`

The server is checking whether the user has privileges to access a cached query result.

- `checking query cache for query`

The server is checking whether the current query is present in the query cache.

- `invalidating query cache entries`

Query cache entries are being marked invalid because the underlying tables have changed.

- `sending cached result to client`

The server is taking the result of a query from the query cache and sending it to the client.

- `storing result in query cache`

The server is storing the result of a query in the query cache.

- `Waiting for query cache lock`

This state occurs while a session is waiting to take the query cache lock. This can happen for any statement that needs to perform some query cache operation, such as an `INSERT` or `DELETE` that invalidates the query cache, a `SELECT` that looks for a cached entry, `RESET QUERY CACHE`, and so forth.

8.14.5 Replication Master Thread States

The following list shows the most common states you may see in the `State` column for the master's `Binlog Dump` thread. If you see no `Binlog Dump` threads on a master server, this means that replication is not running—that is, that no slaves are currently connected.

- `Finished reading one binlog; switching to next binlog`

The thread has finished reading a binary log file and is opening the next one to send to the slave.

- `Master has sent all binlog to slave; waiting for binlog to be updated`

The thread has read all outstanding updates from the binary logs and sent them to the slave. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the master.

- `Sending binlog event to slave`

Binary logs consist of *events*, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the slave.

- `Waiting to finalize termination`

A very brief state that occurs as the thread is stopping.

8.14.6 Replication Slave I/O Thread States

The following list shows the most common states you see in the `State` column for a slave server I/O thread. This state also appears in the `Slave_IO_State` column displayed by `SHOW SLAVE STATUS`, so you can get a good view of what is happening by using that statement.

- `Checking master version`

A state that occurs very briefly, after the connection to the master is established.

- `Connecting to master`

The thread is attempting to connect to the master.

- `Queueing master event to the relay log`

The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- `Reconnecting after a failed binlog dump request`

The thread is trying to reconnect to the master.

- `Reconnecting after a failed master event read`

The thread is trying to reconnect to the master. When connection is established again, the state becomes `Waiting for master to send event`.

- `Registering slave on master`

A state that occurs very briefly after the connection to the master is established.

- `Requesting binlog dump`

A state that occurs very briefly, after the connection to the master is established. The thread sends to the master a request for the contents of its binary logs, starting from the requested binary log file name and position.

- `Waiting for master to send event`

The thread has connected to the master and is waiting for binary log events to arrive. This can last for a long time if the master is idle. If the wait lasts for `slave_net_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- `Waiting for master update`

The initial state before `Connecting to master`.

- `Waiting for slave mutex on exit`

A state that occurs briefly as the thread is stopping.

- `Waiting for the slave SQL thread to free enough relay log space`

You are using a nonzero `relay_log_space_limit` value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- `Waiting to reconnect after a failed binlog dump request`

If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE MASTER TO` statement.

- `Waiting to reconnect after a failed master event read`

An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement (default 60) before attempting to reconnect.

8.14.7 Replication Slave SQL Thread States

The following list shows the most common states you may see in the `State` column for a slave server SQL thread:

- `Waiting for the next event in relay log`

The initial state before `Reading event from the relay log`.

- `Reading event from the relay log`

The thread has read an event from the relay log so that the event can be processed.

- `Making temp file`

The thread is executing a `LOAD DATA` statement and is creating a temporary file containing the data from which the slave will read rows.

- `Slave has read all relay log; waiting for the slave I/O thread to update it`

The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- `Waiting for slave mutex on exit`

A very brief state that occurs as the thread is stopping.

The `State` column for the I/O thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and is executing it.

8.14.8 Replication Slave Connection Thread States

These thread states occur on a replication slave but are associated with connection threads, not with the I/O or SQL threads.

- `Changing master`

The thread is processing a `CHANGE MASTER TO` statement.

- `Killing slave`

The thread is processing a `STOP SLAVE` statement.

- `Opening master dump table`

This state occurs after `Creating table from master dump`.

- `Reading master dump table data`

This state occurs after `Opening master dump table`.

- `Rebuilding the index on master dump table`

This state occurs after `Reading master dump table data`.

8.14.9 NDB Cluster Thread States

- `Committing events to binlog`

- `Opening mysql.ndb_apply_status`

- `Processing events`

The thread is processing events for binary logging.

- `Processing events from schema table`

The thread is doing the work of schema replication.

- `Shutting down`

- `Syncing ndb table schema operation and binlog`

This is used to have a correct binary log of schema operations for NDB.

- `Waiting for allowed to take ndbcluster global schema lock`

The thread is waiting for permission to take a global schema lock. Added in MySQL NDB Cluster 7.2.

- `Waiting for event from ndbcluster`

The server is acting as an SQL node in an NDB Cluster, and is connected to a cluster management node.

- `Waiting for first event from ndbcluster`

- `Waiting for ndbcluster binlog update to reach current position`

- `Waiting for ndbcluster global schema lock`

The thread is waiting for a global schema lock held by another thread to be released. Added in MySQL NDB Cluster 7.2.

- `Waiting for ndbcluster to start`

- `Waiting for schema epoch`

The thread is waiting for a schema epoch (that is, a global checkpoint).

8.14.10 Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

- `Clearing`

The scheduler thread or a thread that was executing an event is terminating and is about to end.

- `Initialized`

The scheduler thread or a thread that will execute an event has been initialized.

- `Waiting for next activation`

The scheduler has a nonempty event queue but the next activation is in the future.

- `Waiting for scheduler to stop`

The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

- `Waiting on empty queue`

The scheduler's event queue is empty and it is sleeping.

Chapter 9 Language Structure

Table of Contents

| 9.4 User-Defined Variables | 1009 |
| 9.5 Expressions | 1012 |
| 9.6 Comment Syntax | 1016 |

This chapter discusses the rules for writing the following elements of [SQL](#) statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Keywords and reserved words
- User-defined and system variables
- Comments

9.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal and bit values, boolean values, and [NULL](#). The section also covers various nuances that you may encounter when dealing with these basic types in MySQL.

9.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote (`'`) or double quote (`"`) characters. Examples:

```
'a string'
"another string"
```

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```
'a string'
'a' ' ' 'string'
```

If the [ANSI_QUOTES](#) SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

A *binary string* is a string of bytes. Every binary string has a character set and collation named `binary`. A *nonbinary string* is a string of characters. It has a character set other than `binary` and a collation that is compatible with the character set.

For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte; comparisons use numeric byte values. For nonbinary strings, the unit is the character and some character sets support multibyte characters; comparisons use numeric character code values. Character code ordering is a function of the string collation. (For more information, see [Section 10.8.5, “The binary Collation Compared to `_bin` Collations”](#).)

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';
SELECT _binary'string';
SELECT _utf8'string' COLLATE utf8_danish_ci;
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information about these forms of string syntax, see [Section 10.3.7, “The National Character Set”](#), and [Section 10.3.8, “Character Set Introducers”](#).

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the *escape character*. MySQL recognizes the escape sequences shown in [Table 9.1, “Special Character Escape Sequences”](#). For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, `\x` is just `x`. These sequences are case-sensitive. For example, `\b` is interpreted as a backspace, but `\B` is interpreted as `B`. Escape processing is done according to the character set indicated by the `character_set_connection` system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in [Section 10.3.6, “Character String Literal Character Set and Collation”](#).

Table 9.1 Special Character Escape Sequences

| Escape Sequence | Character Represented by Sequence |
|-----------------|--|
| <code>\0</code> | An ASCII NUL (<code>x'00'</code>) character |
| <code>\'</code> | A single quote (<code>'</code>) character |
| <code>\"</code> | A double quote (<code>"</code>) character |
| <code>\b</code> | A backspace character |
| <code>\n</code> | A newline (linefeed) character |
| <code>\r</code> | A carriage return character |
| <code>\t</code> | A tab character |
| <code>\Z</code> | ASCII 26 (Control+Z); see note following the table |
| <code>\\</code> | A backslash (<code>\</code>) character |
| <code>\%</code> | A <code>%</code> character; see note following the table |
| <code>_</code> | A <code>_</code> character; see note following the table |

The ASCII 26 character can be encoded as `\Z` to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

The `\%` and `_` sequences are used to search for literal instances of `%` and `_` in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the `LIKE` operator in [Section 12.7.1, “String Comparison Functions and Operators”](#). If you use `\%` or `_` outside of pattern-matching contexts, they evaluate to the strings `\%` and `_`, not to `%` and `_`.

There are several ways to include quote characters within a string:

- A `'` inside a string quoted with `'` may be written as `''`.
- A `"` inside a string quoted with `"` may be written as `""`.
- Precede the quote character by an escape character (`\`).
- A `'` inside a string quoted with `"` needs no special treatment and need not be doubled or escaped. In the same way, `"` inside a string quoted with `'` needs no special treatment.

The following `SELECT` statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', '"hello"', '"hello"', 'hel'lo', '\hello';
+-----+-----+-----+-----+-----+
| hello | "hello" | "hello" | hel'lo | \hello |
+-----+-----+-----+-----+-----+

mysql> SELECT "hello", "'hello'", "'hello'", "hel"lo", "\"hello";
+-----+-----+-----+-----+-----+
| hello | 'hello' | 'hello' | hel"lo | "\"hello" |
+-----+-----+-----+-----+-----+

mysql> SELECT 'This\nIs\nFour\nLines';
+-----+
| This
Is
Four
Lines |
+-----+

mysql> SELECT 'disappearing\ backslash';
+-----+
| disappearing backslash |
+-----+
```

To insert binary data into a string column (such as a `BLOB` column), you should represent certain characters by escape sequences. Backslash (`\`) and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape `NUL` or Control+Z. The `mysql` client truncates quoted strings containing `NUL` characters if they are not escaped, and Control+Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see [Table 9.1, “Special Character Escape Sequences”](#).

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the `mysql_real_escape_string()` C API function to escape characters. See [Section 23.7.6.53, “mysql_real_escape_string\(\)”](#). Within SQL statements that construct other SQL statements, you can use the `QUOTE()` function. The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See [Section 23.9, “MySQL Perl API”](#). Other language interfaces may provide a similar capability.
- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data

values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

9.1.2 Numeric Literals

Number literals include exact-value (integer and [DECIMAL](#)) literals and approximate-value (floating-point) literals.

Integers are represented as a sequence of digits. Numbers may include `.` as a decimal separator. Numbers may be preceded by `-` or `+` to indicate a negative or positive value, respectively. Numbers represented in scientific notation with a mantissa and exponent are approximate-value numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The [DECIMAL](#) data type is a fixed-point type and calculations are exact. In MySQL, the [DECIMAL](#) type has several synonyms: [NUMERIC](#), [DEC](#), [FIXED](#). The integer types also are exact-value types. For more information about exact-value calculations, see [Section 12.19, "Precision Math"](#).

The [FLOAT](#) and [DOUBLE](#) data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with [FLOAT](#) or [DOUBLE](#) are [DOUBLE PRECISION](#) and [REAL](#).

An integer may be used in floating-point context; it is interpreted as the equivalent floating-point number.

9.1.3 Date and Time Literals

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of `'2015-07-21'`, `'20150721'`, and `20150721` as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, see [Section 11.2, "Date and Time Data Types"](#).

Standard SQL and ODBC Date and Time Literals. Standard SQL permits temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes those constructions and also the corresponding ODBC syntax:

```
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

However, MySQL ignores the type keyword and each of the preceding constructions produces the string value `'str'`, with a type of [VARCHAR](#).

String and Numeric Literals in Date and Time Context. MySQL recognizes [DATE](#) values in these formats:

- As a string in either `'YYYY-MM-DD'` or `'YY-MM-DD'` format. A "relaxed" syntax is permitted: Any punctuation character may be used as the delimiter between date parts. For example, `'2012-12-31'`, `'2012/12/31'`, `'2012^12^31'`, and `'2012@12@31'` are equivalent.

- As a string with no delimiters in either `'YYYYMMDD'` or `'YYMMDD'` format, provided that the string makes sense as a date. For example, `'20070523'` and `'070523'` are interpreted as `'2007-05-23'`, but `'071332'` is illegal (it has nonsensical month and day parts) and becomes `'0000-00-00'`.
- As a number in either `YYYYMMDD` or `YYMMDD` format, provided that the number makes sense as a date. For example, `19830905` and `830905` are interpreted as `'1983-09-05'`.

MySQL recognizes `DATETIME` and `TIMESTAMP` values in these formats:

- As a string in either `'YYYY-MM-DD hh:mm:ss'` or `'YY-MM-DD hh:mm:ss'` format. A “relaxed” syntax is permitted here, too: Any punctuation character may be used as the delimiter between date parts or time parts. For example, `'2012-12-31 11:30:45'`, `'2012^12^31 11+30+45'`, `'2012/12/31 11*30*45'`, and `'2012@12@31 11^30^45'` are equivalent.

The date and time parts can be separated by `T` rather than a space. For example, `'2012-12-31 11:30:45'` and `'2012-12-31T11:30:45'` are equivalent.

- As a string with no delimiters in either `'YYYYMMDDhhmmss'` or `'YYMMDDhhmmss'` format, provided that the string makes sense as a date. For example, `'20070523091528'` and `'070523091528'` are interpreted as `'2007-05-23 09:15:28'`, but `'071122129015'` is illegal (it has a nonsensical minute part) and becomes `'0000-00-00 00:00:00'`.
- As a number in either `YYYYMMDDhhmmss` or `YYMMDDhhmmss` format, provided that the number makes sense as a date. For example, `19830905132800` and `830905132800` are interpreted as `'1983-09-05 13:28:00'`.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into `DATETIME` or `TIMESTAMP` columns. For information about fractional seconds support in MySQL, see [Section 11.2.7, “Fractional Seconds in Time Values”](#).

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

- Year values in the range `70-99` become `1970-1999`.
- Year values in the range `00-69` become `2000-2069`.

See also [Section 11.2.9, “2-Digit Years in Dates”](#).

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. `'2015-6-9'` is the same as `'2015-06-09'`. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. `'2015-10-30 1:2:3'` is the same as `'2015-10-30 01:02:03'`.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in `YYYYMMDD` or `YYYYMMDDhhmmss` format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in `YYMMDD` or `YYMMDDhhmmss` format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify `'9903'`, thinking that represents March, 1999, MySQL converts it to the “zero” date value. This occurs because the year and month values are `99` and `03`, but the day part is completely missing. However,

you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value '1999-03-00', use '990300'.

MySQL recognizes `TIME` values in these formats:

- As a string in '`D hh:mm:ss`' format. You can also use one of the following “relaxed” syntaxes: '`hh:mm:ss`', '`hh:mm`', '`D hh:mm`', '`D hh`', or '`ss`'. Here `D` represents days and can have a value from 0 to 34.
- As a string with no delimiters in '`hhmmss`' format, provided that it makes sense as a time. For example, '101112' is understood as '10:11:12', but '109712' is illegal (it has a nonsensical minute part) and becomes '00:00:00'.
- As a number in `hhmmss` format, provided that it makes sense as a time. For example, 101112 is understood as '10:11:12'. The following alternative formats are also understood: `ss`, `mmss`, or `hhmmss`.

A trailing fractional seconds part is recognized in the '`D hh:mm:ss.fraction`', '`hh:mm:ss.fraction`', '`hhmmss.fraction`', and `hhmmss.fraction` time formats, where `fraction` is the fractional part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into `TIME` columns. For information about fractional seconds support in MySQL, see [Section 11.2.7, “Fractional Seconds in Time Values”](#).

For `TIME` values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than 10. '8:3:2' is the same as '08:03:02'.

9.1.4 Hexadecimal Literals

Hexadecimal literal values are written using `X'val'` or `0xval` notation, where `val` contains hexadecimal digits (0..9, A..F). Lettercase of the digits and of any leading `x` does not matter. A leading `0x` is case-sensitive and cannot be written as `0X`.

Legal hexadecimal literals:

```
X'01AF'
X'01af'
x'01AF'
x'01af'
0x01AF
0x01af
```

Illegal hexadecimal literals:

```
X'0G'   (G is not a hexadecimal digit)
0X01AF (0X must be written as 0x)
```

Values written using `X'val'` notation must contain an even number of digits or a syntax error occurs. To correct the problem, pad the value with a leading zero:

```
mysql> SET @s = X'FFF';
ERROR 1064 (42000): You have an error in your SQL syntax;
check the manual that corresponds to your MySQL server
version for the right syntax to use near 'X'FFF''

mysql> SET @s = X'0FFF';
Query OK, 0 rows affected (0.00 sec)
```

Values written using `0xval` notation that contain an odd number of digits are treated as having an extra leading 0. For example, `0xaaa` is interpreted as `0x0aaa`.

By default, a hexadecimal literal is a binary string, where each pair of hexadecimal digits represents a character:

```
mysql> SELECT X'4D7953514C', CHARSET(X'4D7953514C');
+-----+-----+
| X'4D7953514C' | CHARSET(X'4D7953514C') |
+-----+-----+
| MySQL          | binary                  |
+-----+-----+
mysql> SELECT 0x5461626c65, CHARSET(0x5461626c65);
+-----+-----+
| 0x5461626c65 | CHARSET(0x5461626c65) |
+-----+-----+
| Table         | binary                  |
+-----+-----+
```

A hexadecimal literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] X'val' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1 X'4D7953514C';
SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;
```

The examples use `X'val'` notation, but `0xval` notation permits introducers as well. For information about introducers, see [Section 10.3.8, "Character Set Introducers"](#).

In numeric contexts, MySQL treats a hexadecimal literal like a `BIGINT` (64-bit integer). To ensure numeric treatment of a hexadecimal literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a hexadecimal literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A   | 65  | 65  |
+-----+-----+-----+
```

An empty hexadecimal value (`X''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(X''), LENGTH(X'');
+-----+-----+
| CHARSET(X'') | LENGTH(X'') |
+-----+-----+
| binary      | 0           |
+-----+-----+
mysql> SELECT X''+0;
+-----+
| X''+0 |
+-----+
| 0     |
+-----+
```

The `X'val'` notation is based on standard SQL. The `0x` notation is based on ODBC, for which hexadecimal strings are often used to supply values for `BLOB` columns.

To convert a string or a number to a string in hexadecimal format, use the `HEX()` function:

```
mysql> SELECT HEX('cat');
+-----+
| HEX('cat') |
+-----+
| 636174     |
+-----+
```

```
mysql> SELECT X'636174';
+-----+
| X'636174' |
+-----+
| cat       |
+-----+
```

9.1.5 Bit-Value Literals

Bit-value literals are written using `b'val'` or `0bval` notation. `val` is a binary value written using zeros and ones. Lettercase of any leading `b` does not matter. A leading `0b` is case-sensitive and cannot be written as `0B`.

Legal bit-value literals:

```
b'01'
B'01'
0b01
```

Illegal bit-value literals:

```
b'2'      (2 is not a binary digit)
0B01     (0B must be written as 0b)
```

By default, a bit-value literal is a binary string:

```
mysql> SELECT b'1000001', CHARSET(b'1000001');
+-----+-----+
| b'1000001' | CHARSET(b'1000001') |
+-----+-----+
| A          | binary              |
+-----+-----+
mysql> SELECT 0b1100001, CHARSET(0b1100001);
+-----+-----+
| 0b1100001 | CHARSET(0b1100001) |
+-----+-----+
| a          | binary              |
+-----+-----+
```

A bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] b'val' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1 b'1000001';
SELECT _utf8 0b1000001 COLLATE utf8_danish_ci;
```

The examples use `b'val'` notation, but `0bval` notation permits introducers as well. For information about introducers, see [Section 10.3.8, "Character Set Introducers"](#).

In numeric contexts, MySQL treats a bit literal like an integer. To ensure numeric treatment of a bit literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a bit literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = b'1100001';
mysql> SET @v2 = b'1100001'+0;
mysql> SET @v3 = CAST(b'1100001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1  | @v2  | @v3  |
+-----+-----+-----+
| a    | 97   | 97   |
+-----+-----+-----+
```

An empty bit value (`b''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(b''), LENGTH(b'');
+-----+-----+
| CHARSET(b'') | LENGTH(b'') |
+-----+-----+
| binary      |           0 |
+-----+-----+
mysql> SELECT b''+0;
+-----+
| b''+0 |
+-----+
|     0 |
+-----+
```

Bit-value notation is convenient for specifying values to be assigned to `BIT` columns:

```
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
```

Bit values in result sets are returned as binary values, which may not display well. To convert a bit value to printable form, use it in numeric context or use a conversion function such as `BIN()` or `HEX()`. High-order 0 digits are not displayed in the converted value.

```
mysql> SELECT b+0, BIN(b), OCT(b), HEX(b) FROM t;
+-----+-----+-----+-----+
| b+0 | BIN(b) | OCT(b) | HEX(b) |
+-----+-----+-----+-----+
| 255 | 11111111 | 377    | FF     |
| 10  | 1010    | 12     | A      |
| 5   | 101     | 5      | 5      |
+-----+-----+-----+-----+
```

9.1.6 Boolean Literals

The constants `TRUE` and `FALSE` evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
-> 1, 1, 0, 0
```

9.1.7 NULL Values

The `NULL` value means “no data.” `NULL` can be written in any lettercase. A synonym is `\N` (case-sensitive).

Be aware that the `NULL` value is different from values such as 0 for numeric types or the empty string for string types. For more information, see [Section B.4.4.3, “Problems with NULL Values”](#).

For text file import or export operations performed with `LOAD DATA` or `SELECT ... INTO OUTFILE`, `NULL` is represented by the `\N` sequence. See [Section 13.2.6, “LOAD DATA Statement”](#).

For sorting with `ORDER BY`, `NULL` values sort before other values for ascending sorts, after other values for descending sorts.

9.2 Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. [Section 9.2.1, “Identifier Length Limits”](#), indicates the

maximum length of each type of identifier. [Section 9.2.3, “Identifier Case Sensitivity”](#), describes which types of identifiers are case-sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you *must* quote it whenever you refer to it. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at [Section 9.3, “Keywords and Reserved Words”](#).

Internally, identifiers are converted to and are stored as Unicode (UTF-8). The permissible Unicode characters in identifiers are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted. Identifiers thus may contain these characters:

- Permitted characters in unquoted identifiers:
 - ASCII: [0-9,a-z,A-Z\$_] (basic Latin letters, digits 0-9, dollar, underscore)
 - Extended: U+0080 .. U+FFFF
- Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
 - ASCII: U+0001 .. U+007F
 - Extended: U+0080 .. U+FFFF
- ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.
- Identifiers may begin with a digit but unless quoted may not consist solely of digits.
- Database, table, and column names cannot end with space characters.

The identifier quote character is the backtick (`):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the `ANSI_QUOTES` SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The `ANSI_QUOTES` mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in [Section 5.1.10, “Server SQL Modes”](#).

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a`b` that contains a column named `c`d`:

```
mysql> CREATE TABLE `a``b` (`c`d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
+-----+-----+
| one | two |
```

```
+-----+-----+
| 1 | 2 |
+-----+-----+
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with *Me* or *MeN*, where *M* and *N* are integers. For example, avoid using `1e` as an identifier, because an expression such as `1e+3` is ambiguous. Depending on context, it might be interpreted as the expression `1e + 3` or as the number `1e+3`.

Be careful when using `MD5()` to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See [Section 9.4, “User-Defined Variables”](#), for more information and examples of workarounds.

Special characters in database and table names are encoded in the corresponding file system names as described in [Section 9.2.4, “Mapping of Identifiers to File Names”](#). If you have databases or tables from an older version of MySQL that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#`. For information about referring to such names or converting them to the newer encoding, see that section.

9.2.1 Identifier Length Limits

The following table describes the maximum length for each type of identifier.

| Identifier Type | Maximum Length (characters) |
|--------------------------|-------------------------------------|
| Database | 64 (NDB storage engine: 63) |
| Table | 64 (NDB storage engine: 63) |
| Column | 64 |
| Index | 64 |
| Constraint | 64 |
| Stored Program | 64 |
| View | 64 |
| Tablespace | 64 |
| Server | 64 |
| Log File Group | 64 |
| Alias | 256 (see exception following table) |
| Compound Statement Label | 16 |

Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

For constraint definitions that include no constraint name, the server internally generates a name derived from the associated table name. For example, internally generated foreign key constraint names consist of the table name plus `_ibfk_` and a number. If the table name is close to the length limit for constraint names, the additional characters required for the constraint name may cause that name to exceed the limit, resulting in an error.

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions that are stored in `.frm` files and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multibyte characters without reducing the number of characters permitted for values stored in these columns.

NDB Cluster imposes a maximum length of 63 characters for names of databases and tables. See [Section 18.1.7.5, “Limits Associated with Database Objects in NDB Cluster”](#).

Values such as user name and host names in MySQL account names are strings rather than identifiers. For information about the maximum length of such values as stored in grant tables, see [Grant Table Scope Column Properties](#).

9.2.2 Identifier Qualifiers

Object names may be unqualified or qualified. An unqualified name is permitted in contexts where interpretation of the name is unambiguous. A qualified name includes at least one qualifier to clarify the interpretive context by overriding a default context or providing missing context.

For example, this statement creates a table using the unqualified name `t1`:

```
CREATE TABLE t1 (i INT);
```

Because `t1` includes no qualifier to specify a database, the statement creates the table in the default database. If there is no default database, an error occurs.

This statement creates a table using the qualified name `db1.t1`:

```
CREATE TABLE db1.t1 (i INT);
```

Because `db1.t1` includes a database qualifier `db1`, the statement creates `t1` in the database named `db1`, regardless of the default database. The qualifier *must* be specified if there is no default database. The qualifier *may* be specified if there is a default database, to specify a database different from the default, or to make the database explicit if the default is the same as the one specified.

Qualifiers have these characteristics:

- An unqualified name consists of a single identifier. A qualified name consists of multiple identifiers.
- The components of a multiple-part name must be separated by period (.) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which to interpret the final identifier.
- The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, `tbl_name.col_name` and `tbl_name . col_name` are equivalent.
- If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write ``my-table`.`my-column``, not ``my-table.my-column``.
- A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

- The syntax `.tbl_name` means the table `tbl_name` in the default database. This syntax is accepted for ODBC compatibility because some ODBC programs prefix table names with a `.` character.

The permitted qualifiers for object names depend on the object type:

- A database name is fully qualified and takes no qualifier:

```
CREATE DATABASE db1;
```

- A table, view, or stored program name may be given a database-name qualifier. Examples of unqualified and qualified names in `CREATE` statements:

```
CREATE TABLE mytable ...;
CREATE VIEW myview ...;
CREATE PROCEDURE myproc ...;
CREATE FUNCTION myfunc ...;
CREATE EVENT myevent ...;

CREATE TABLE mydb.mytable ...;
CREATE VIEW mydb.myview ...;
CREATE PROCEDURE mydb.myproc ...;
CREATE FUNCTION mydb.myfunc ...;
CREATE EVENT mydb.myevent ...;
```

- A trigger is associated with a table, so any qualifier applies to the table name:

```
CREATE TRIGGER mytrigger ... ON mytable ...;

CREATE TRIGGER mytrigger ... ON mydb.mytable ...;
```

- A column name may be given multiple qualifiers to indicate context in statements that reference it, as shown in the following table.

| Column Reference | Meaning |
|--|--|
| <code>col_name</code> | Column <code>col_name</code> from whichever table used in the statement contains a column of that name |
| <code>tbl_name.col_name</code> | Column <code>col_name</code> from table <code>tbl_name</code> of the default database |
| <code>db_name.tbl_name.col_name</code> | Column <code>col_name</code> from table <code>tbl_name</code> of the database <code>db_name</code> |

In other words, a column name may be given a table-name qualifier, which itself may be given a database-name qualifier. Examples of unqualified and qualified column references in `SELECT` statements:

```
SELECT c1 FROM mytable
WHERE c2 > 100;

SELECT mytable.c1 FROM mytable
WHERE mytable.c2 > 100;

SELECT mydb.mytable.c1 FROM mydb.mytable
WHERE mydb.mytable.c2 > 100;
```

You need not specify a qualifier for an object reference in a statement unless the unqualified reference is ambiguous. Suppose that column `c1` occurs only in table `t1`, `c2` only in `t2`, and `c` in both `t1` and `t2`. Any unqualified reference to `c` is ambiguous in a statement that refers to both tables and must be qualified as `t1.c` or `t2.c` to indicate which table you mean:

```
SELECT c1, c2, t1.c FROM t1 INNER JOIN t2
WHERE t2.c > 100;
```

Similarly, to retrieve from a table `t` in database `db1` and from a table `t` in database `db2` in the same statement, you must qualify the table references: For references to columns in those tables, qualifiers

are required only for column names that appear in both tables. Suppose that column `c1` occurs only in table `db1.t`, `c2` only in `db2.t`, and `c` in both `db1.t` and `db2.t`. In this case, `c` is ambiguous and must be qualified but `c1` and `c2` need not be:

```
SELECT c1, c2, db1.t.c FROM db1.t INNER JOIN db2.t
WHERE db2.t.c > 100;
```

Table aliases enable qualified column references to be written more simply:

```
SELECT c1, c2, t1.c FROM db1.t AS t1 INNER JOIN db2.t AS t2
WHERE t2.c > 100;
```

9.2.3 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means such names are not case-sensitive in Windows, but are case-sensitive in most varieties of Unix. One notable exception is macOS, which is Unix-based but uses a default file system type (HFS+) that is not case-sensitive. However, macOS also supports UFS volumes, which are case-sensitive just as on any Unix. See [Section 1.7.1, “MySQL Extensions to Standard SQL”](#). The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.

Note

Although database, table, and trigger names are not case sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column, index, stored routine, and event names are not case sensitive on any platform, nor are column aliases.

However, names of logfile groups are case-sensitive. This differs from standard SQL.

By default, table aliases are case-sensitive on Unix, but not so on Windows or macOS. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` system variable, which you can set when starting `mysqld`. `lower_case_table_names` can take the values shown in the following table. This variable does *not* affect case sensitivity of trigger identifiers. On Unix, the default value of `lower_case_table_names` is 0. On Windows, the default value is 1. On macOS, the default value is 2.

| Value | Meaning |
|-------|---|
| 0 | Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case sensitive. You should <i>not</i> set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or macOS). If you force this variable to 0 with <code>--</code> |

| Value | Meaning |
|-------|---|
| | <code>lower-case-table-names=0</code> on a case-insensitive file system and access <code>MyISAM</code> table names using different lettercases, index corruption may result. |
| 1 | Table names are stored in lowercase on disk and name comparisons are not case-sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases. |
| 2 | Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case sensitive. This works <i>only</i> on file systems that are not case-sensitive! <code>InnoDB</code> table names are stored in lowercase, as for <code>lower_case_table_names=1</code> . |

If you are using MySQL on only one platform, you do not normally have to change the `lower_case_table_names` variable from its default value. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- Use `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.
- Use `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

Exception: If you are using `InnoDB` tables and you are trying to avoid these data transfer problems, you should set `lower_case_table_names` to 1 on all platforms to force names to be converted to lowercase.

If you plan to set the `lower_case_table_names` system variable to 1 on Unix, you must first convert your old database and table names to lowercase before stopping `mysqld` and restarting it with the new variable setting. To do this for an individual table, use `RENAME TABLE`:

```
RENAME TABLE T1 TO t1;
```

To convert one or more entire databases, dump them before setting `lower_case_table_names`, then drop the databases, and reload them after setting `lower_case_table_names`:

1. Use `mysqldump` to dump each database:

```
mysqldump --databases db1 > db1.sql
mysqldump --databases db2 > db2.sql
...
```

Do this for each database that must be recreated.

2. Use `DROP DATABASE` to drop each database.
3. Stop the server, set `lower_case_table_names`, and restart the server.
4. Reload the dump file for each database. Because `lower_case_table_names` is set, each database and table name will be converted to lowercase as it is recreated:

```
mysql < db1.sql
mysql < db2.sql
...
```

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored

routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with `PREPARE`, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of `INFORMATION_SCHEMA` tables. For more information, see [Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”](#).

9.2.4 Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and each table by one or more files in the appropriate database directory. For the table format files (`.FRM`), the data is always stored in this structure and location.

For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the same location as the `FRM` files, or the information may be stored in a separate file. `InnoDB` data is stored in the `InnoDB` data files. If you are using tablespaces with `InnoDB`, then the specific tablespace files you create are used instead.

Any character is legal in database or table identifiers except ASCII NUL (`x'00'`). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters (`a..zA..Z`), digits (`0..9`) and underscore (`_`) are encoded as is. Consequently, their case sensitivity directly depends on file system features.
- All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

| Code Range | Pattern | Number | Used | Unused | Blocks |
|------------|-----------------------------|-------------|------|--------|---------------------------------------|
| 00C0..017F | <code>[@[0..4][g..z]</code> | $5*20= 100$ | 97 | 3 | Latin-1 Supplement + Latin Extended-A |
| 0370..03FF | <code>[@[5..9][g..z]</code> | $5*20= 100$ | 88 | 12 | Greek and Coptic |
| 0400..052F | <code>[@[g..z][0..6]</code> | $20*7= 140$ | 137 | 3 | Cyrillic + Cyrillic Supplement |
| 0530..058F | <code>[@[g..z][7..8]</code> | $20*2= 40$ | 38 | 2 | Armenian |
| 2160..217F | <code>[@[g..z][9]</code> | $20*1= 20$ | 16 | 4 | Number Forms |
| 0180..02AF | <code>[@[g..z][a..k]</code> | $20*11=220$ | 203 | 17 | Latin Extended-B + IPA Extensions |
| 1E00..1EFF | <code>[@[g..z][l..r]</code> | $20*7= 140$ | 136 | 4 | Latin Extended Additional |
| 1F00..1FFF | <code>[@[g..z][s..z]</code> | $20*8= 160$ | 144 | 16 | Greek Extended |
| | <code>[@[a..f][g..z]</code> | $6*20= 120$ | 0 | 120 | RESERVED |
| 24B6..24E9 | <code>[@[@[a..z]</code> | 26 | 26 | 0 | Enclosed Alphanumerics |
| FF21..FF5A | <code>[@[a..z][@]</code> | 26 | 26 | 0 | Halfwidth and Fullwidth forms |

One of the bytes in the sequence encodes lettercase. For example: `LATIN CAPITAL LETTER A WITH GRAVE` is encoded as `@0G`, whereas `LATIN SMALL LETTER A WITH GRAVE` is encoded as `@0g`. Here the third byte (`G` or `g`) indicates lettercase. (On a case-insensitive file system, both letters will be treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as

in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

- All nonletter characters except underscore (`_`), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hexadecimal digits `a..f`:

```
0x003F -> @003f
0xFFFF -> @ffff
```

The hexadecimal values correspond to character values in the `ucs2` double-byte character set.

On Windows, some names such as `nul`, `prn`, and `aux` are encoded by appending `@@@` to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

If you have databases or tables from a version of MySQL older than 5.1.6 that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#` in the output from `INFORMATION_SCHEMA` tables or `SHOW` statements. For example, if you have a table named `a@b` and its name encoding has not been updated, `SHOW TABLES` displays it like this:

```
mysql> SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| #mysql50#a@b  |
+-----+
```

To refer to such a name for which the encoding has not been updated, you must supply the `#mysql50#` prefix:

```
mysql> SHOW COLUMNS FROM `a@b`;
ERROR 1146 (42S02): Table 'test.a@b' doesn't exist

mysql> SHOW COLUMNS FROM `#mysql50#a@b`;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| i     | int(11)| YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

To update old names to eliminate the need to use the special prefix to refer to them, re-encode them with `mysqlcheck`. The following commands update all names to the new encoding:

```
mysqlcheck --check-upgrade --all-databases
mysqlcheck --fix-db-names --fix-table-names --all-databases
```

To check only specific databases or tables, omit `--all-databases` and provide the appropriate database or table arguments. For information about `mysqlcheck` invocation syntax, see [Section 4.5.3](#), “`mysqlcheck` — A Table Maintenance Program”.

Note

The `#mysql50#` prefix is intended only to be used internally by the server. You should not create databases or tables with names that use this prefix.

Also, `mysqlcheck` cannot fix names that contain literal instances of the `@` character that is used for encoding special characters. If you have databases or tables that contain this character, use `mysqldump` to dump them before upgrading to MySQL 5.1.6 or later, and then reload the dump file after upgrading.

9.2.5 Function Name Parsing and Resolution

MySQL supports built-in (native) functions, user-defined functions (UDFs), and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.

- [Built-In Function Name Parsing](#)
- [Function Name Resolution](#)

Built-In Function Name Parsing

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the `IGNORE_SPACE` SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to `count` is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;  
CREATE TABLE count (i INT);
```

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following (parenthesis character.
- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. `COUNT` is one such name. The `sql_functions[]` array in the `sql/lex.h` source file lists the names of these special functions for which following whitespace determines their interpretation.

The following list names the functions in MySQL 5.5 that are affected by the `IGNORE_SPACE` setting and listed as special in the `sql/lex.h` source file. You may find it easiest to treat the no-whitespace requirement as applying to all function calls.

- `ADDDATE`
- `BIT_AND`
- `BIT_OR`
- `BIT_XOR`
- `CAST`
- `COUNT`
- `CURDATE`
- `CURTIME`
- `DATE_ADD`

- DATE_SUB
- EXTRACT
- GROUP_CONCAT
- MAX
- MID
- MIN
- NOW
- POSITION
- SESSION_USER
- STD
- STDDEV
- STDDEV_POP
- STDDEV_SAMP
- SUBDATE
- SUBSTR
- SUBSTRING
- SUM
- SYSDATE
- SYSTEM_USER
- TRIM
- VARIANCE
- VAR_POP
- VAR_SAMP

For functions not listed as special in `sql/lex.h`, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. `ASCII` is one such name. However, for these nonaffected function names, interpretation may vary in expression context: `func_name ()` is interpreted as a built-in function if there is one with the given name; if not, `func_name ()` is interpreted as a user-defined function or stored function if one exists with that name.

The `IGNORE_SPACE` SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

- With `IGNORE_SPACE` disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'count(i INT)'
```

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```
CREATE TABLE count (i INT);
CREATE TABLE `count` (i INT);
CREATE TABLE `count` (i INT);
```

- With `IGNORE_SPACE` enabled, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```
SELECT COUNT(*) FROM mytable;
SELECT COUNT (*) FROM mytable;
```

However, enabling `IGNORE_SPACE` also has the side effect that the parser treats the affected function names as reserved words (see [Section 9.3, “Keywords and Reserved Words”](#)). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function calls with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with `IGNORE_SPACE` enabled, both of the following statements fail with a syntax error because the parser interprets `count` as a reserved word:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

To use the function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count` (i INT);
CREATE TABLE `count` (i INT);
```

To enable the `IGNORE_SPACE` SQL mode, use this statement:

```
SET sql_mode = 'IGNORE_SPACE';
```

`IGNORE_SPACE` is also enabled by certain other composite modes such as `ANSI` that include it in their value:

```
SET sql_mode = 'ANSI';
```

Check [Section 5.1.10, “Server SQL Modes”](#), to see which composite modes enable `IGNORE_SPACE`.

To minimize the dependency of SQL code on the `IGNORE_SPACE` setting, use these guidelines:

- Avoid creating UDFs or stored functions that have the same name as a built-in function.
- Avoid using function names in nonexpression context. For example, these statements use `count` (one of the affected function names affected by `IGNORE_SPACE`), so they fail with or without whitespace following the name if `IGNORE_SPACE` is enabled:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

If you must use a function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count` (i INT);
CREATE TABLE `count` (i INT);
```

Function Name Resolution

The following rules describe how the server resolves references to function names for function creation and invocation:

- Built-in functions and user-defined functions

An error occurs if you try to create a UDF with the same name as a built-in function.

- Built-in functions and stored functions

It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named `PI` in the `test` schema, invoke it as `test.PI()` because the server resolves `PI()` without a qualifier as a reference to the built-in function. The server generates a warning if the stored function name collides with a built-in function name. The warning can be displayed with `SHOW WARNINGS`.

- User-defined functions and stored functions

User-defined functions and stored functions share the same namespace, so you cannot create a UDF and a stored function with the same name.

The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:

- If you have already created a user-defined function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF and `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. Then modify any affected code to use the new name.
- If a new version of MySQL implements a built-in function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change calls to the function so that they use a schema qualifier (that is, use `schema_name.func_name()` syntax). In either case, modify any affected code accordingly.

9.3 Keywords and Reserved Words

Keywords are words that have significance in SQL. Certain keywords, such as `SELECT`, `DELETE`, or `BIGINT`, are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Nonreserved keywords are permitted as identifiers without quoting. Reserved words are permitted as identifiers if you quote them as described in [Section 9.2, “Schema Object Names”](#):

```
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'interval (begin INT, end INT)'
```

`BEGIN` and `END` are keywords but not reserved, so their use as identifiers does not require quoting. `INTERVAL` is a reserved keyword and must be quoted to be used as an identifier:

```
mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, `COUNT` is acceptable as a column name. However, by default, no whitespace is permitted in function invocations between the function name and the following `(` character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further details on recognition of function names, see [Section 9.2.5, “Function Name Parsing and Resolution”](#).

- [MySQL 5.5 Removed Keywords and Reserved Words](#)

MySQL 5.5 Keywords and Reserved Words

The following list shows the keywords and reserved words in MySQL 5.5, along with changes to individual words from version to version. Reserved keywords are marked with (R). In addition, `__FILENAME` is reserved.

At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the reserved words in the list are forbidden by standard SQL as column or table names (for example, `GROUP`). A few are reserved because MySQL needs them and uses a `yacc` parser.

[A](#) | [B](#) | [C](#) | [D](#) | [E](#) | [F](#) | [G](#) | [H](#) | [I](#) | [J](#) | [K](#) | [L](#) | [M](#) | [N](#) | [O](#) | [P](#) | [Q](#) | [R](#) | [S](#) | [T](#) | [U](#) | [V](#) | [W](#) | [X](#) | [Y](#) | [Z](#)

MySQL 5.5 Removed Keywords and Reserved Words

The following list shows the keywords and reserved words that are removed in MySQL 5.5, compared to MySQL 5.1. Reserved keywords are marked with (R).

- FRAC_SECOND
- INNOBASE
- INNODB
- SQL_TSI_FRAC_SECOND

9.4 User-Defined Variables

You can store a value in a user-defined variable in one statement and refer to it later in another statement. This enables you to pass values from one statement to another.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumeric characters, `.`, `_`, and `$`. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `@`my-var``).

User-defined variables are session specific. A user variable defined by one client cannot be seen or used by other clients. All variables for a given client session are automatically freed when that client exits.

User variable names are not case-sensitive.

One way to set a user-defined variable is by issuing a `SET` statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For `SET`, either `=` or `:=` can be used as the assignment operator.

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or `NULL` value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Hexadecimal or bit values assigned to user variables are treated as binary strings. To assign a hexadecimal or bit value as a number to a user variable, use it in numeric context. For example, add 0 or use `CAST(... AS UNSIGNED)`:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A   | 65  | 65  |
+-----+-----+-----+
mysql> SET @v1 = b'1000001';
mysql> SET @v2 = b'1000001'+0;
mysql> SET @v3 = CAST(b'1000001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A   | 65  | 65  |
+-----+-----+-----+
```

If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of `NULL` and a type of string.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the `LIMIT` clause of a `SELECT` statement, or the `IGNORE N LINES` clause of a `LOAD DATA` statement.

You can also assign a value to a user variable in statements other than `SET`. In this case, the assignment operator must be `:=` and not `=` because the latter is treated as the comparison operator `=` in statements other than `SET`:

```
mysql> SET @t1=1, @t2=2, @t3:=4;
mysql> SELECT @t1, @t2, @t3, @t4 := @t1+@t2+@t3;
+-----+-----+-----+-----+
| @t1 | @t2 | @t3 | @t4 := @t1+@t2+@t3 |
+-----+-----+-----+-----+
| 1   | 2   | 4   | 7                   |
+-----+-----+-----+-----+
```

As a general rule, other than in `SET` statements, you should never assign a value to a user variable and read the value within the same statement. For example, to increment a variable, this is okay:

```
SET @a = @a + 1;
```

For other statements, such as `SELECT`, you might get the results you expect, but this is not guaranteed. In the following statement, you might think that MySQL will evaluate `@a` first and then do an assignment second:

```
SELECT @a, @a:=@a+1, ...;
```

However, the order of evaluation for expressions involving user variables is undefined.

Another issue with assigning a value to a variable and reading the value within the same non-`SET` statement is that the default result type of a variable is based on its type at the start of the statement. The following example illustrates this:

```
mysql> SET @a='test';
mysql> SELECT @a, (@a:=20) FROM tbl_name;
```

For this `SELECT` statement, MySQL reports to the client that column one is a string and converts all accesses of `@a` to strings, even though `@a` is set to a number for the second row. After the `SELECT` statement executes, `@a` is regarded as a number for the next statement.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to `0`, `0.0`, or `' '` to define its type before you use it.

In a `SELECT` statement, each select expression is evaluated only when sent to the client. This means that in a `HAVING`, `GROUP BY`, or `ORDER BY` clause, referring to a variable that is assigned a value in the select expression list does *not* work as expected:

```
mysql> SELECT (@aa:=id) AS a, (@aa+3) AS b FROM tbl_name HAVING b=5;
```

The reference to `b` in the `HAVING` clause refers to an alias for an expression in the select list that uses `@aa`. This does not work as expected: `@aa` contains the value of `id` from the previous selected row, not from the current row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as `SELECT`. This is true even if the variable is quoted, as shown in the following example:

```
mysql> SELECT c1 FROM t;
+-----+
| c1 |
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)

mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
| @col |
+-----+
| c1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'

mysql> SET @col = "`c1`";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
| @col |
+-----+
| `c1` |
+-----+
1 row in set (0.00 sec)
```

An exception to this principle that user variables cannot be used to provide identifiers, is when you are constructing a string for use as a prepared statement to execute later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

```
mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;
+-----+
| c1 |
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)
```

See [Section 13.5, “Prepared Statements”](#), for more information.

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```
<?php
    $mysqli = new mysqli("localhost", "user", "pass", "test");

    if( mysqli_connect_errno() )
        die("Connection failed: %s\n", mysqli_connect_error());

    $col = "c1";

    $query = "SELECT $col FROM t";

    $result = $mysqli->query($query);

    while($row = $result->fetch_assoc())
    {
        echo "<p>" . $row["$col"] . "</p>\n";
    }

    $result->close();

    $mysqli->close();
?>
```

Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

9.5 Expressions

This section lists the grammar rules that expressions must follow in MySQL and provides additional information about the types of terms that may appear in expressions.

- [Expression Syntax](#)
- [Expression Term Notes](#)
- [Temporal Intervals](#)

Expression Syntax

The following grammar rules define expression syntax in MySQL. The grammar shown here is based on that given in the `sql/sql_yacc.yy` file of MySQL source distributions. For additional information about some of the expression terms, see [Expression Term Notes](#).

```
expr:
    expr OR expr
  |  expr || expr
  |  expr XOR expr
  |  expr AND expr
```

```

| expr && expr
| NOT expr
| ! expr
| boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
| boolean_primary

boolean_primary:
  boolean_primary IS [NOT] NULL
| boolean_primary <=> predicate
| boolean_primary comparison_operator predicate
| boolean_primary comparison_operator {ALL | ANY} (subquery)
| predicate

comparison_operator: = | >= | > | <= | < | <> | !=

predicate:
  bit_expr [NOT] IN (subquery)
| bit_expr [NOT] IN (expr [, expr] ...)
| bit_expr [NOT] BETWEEN bit_expr AND predicate
| bit_expr SOUNDS LIKE bit_expr
| bit_expr [NOT] LIKE simple_expr [ESCAPE simple_expr]
| bit_expr [NOT] REGEXP bit_expr
| bit_expr

bit_expr:
  bit_expr | bit_expr
| bit_expr & bit_expr
| bit_expr << bit_expr
| bit_expr >> bit_expr
| bit_expr + bit_expr
| bit_expr - bit_expr
| bit_expr * bit_expr
| bit_expr / bit_expr
| bit_expr DIV bit_expr
| bit_expr MOD bit_expr
| bit_expr % bit_expr
| bit_expr ^ bit_expr
| bit_expr + interval_expr
| bit_expr - interval_expr
| simple_expr

simple_expr:
  literal
| identifier
| function_call
| simple_expr COLLATE collation_name
| param_marker
| variable
| simple_expr || simple_expr
| + simple_expr
| - simple_expr
| ~ simple_expr
| ! simple_expr
| BINARY simple_expr
| (expr [, expr] ...)
| ROW (expr, expr [, expr] ...)
| (subquery)
| EXISTS (subquery)
| {identifier expr}
| match_expr
| case_expr
| interval_expr

```

For operator precedence, see [Section 12.3.1, “Operator Precedence”](#). The precedence and meaning of some operators depends on the SQL mode:

- By default, `||` is a logical `OR` operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See [Section 5.1.10, “Server SQL Modes”](#).

Expression Term Notes

For literal value syntax, see [Section 9.1, “Literal Values”](#).

For identifier syntax, see [Section 9.2, “Schema Object Names”](#).

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: [Section 9.4, “User-Defined Variables”](#)
- System variables: [Section 5.1.8, “Using System Variables”](#)
- Stored program local variables: [Section 13.6.4.1, “Local Variable DECLARE Statement”](#)
- Stored program parameters: [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#)

param_marker is `?` as used in prepared statements for placeholders. See [Section 13.5.1, “PREPARE Statement”](#).

(subquery) indicates a subquery that returns a single value; that is, a scalar subquery. See [Section 13.2.10.1, “The Subquery as Scalar Operand”](#).

{identifier expr} is ODBC escape syntax and is accepted for ODBC compatibility. The value is *expr*. The `{` and `}` curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

match_expr indicates a `MATCH` expression. See [Section 12.9, “Full-Text Search Functions”](#).

case_expr indicates a `CASE` expression. See [Section 12.4, “Control Flow Functions”](#).

interval_expr represents a temporal interval. See [Temporal Intervals](#).

Temporal Intervals

interval_expr in expressions represents a temporal interval. Intervals have this syntax:

```
INTERVAL expr unit
```

expr represents a quantity. *unit* represents the unit for interpreting the quantity; it is a specifier such as `hour`, `day`, or `week`. The `INTERVAL` keyword and the *unit* specifier are not case sensitive.

The following table shows the expected form of the *expr* argument for each *unit* value.

Table 9.2 Temporal Interval Expression and Unit Arguments

| <i>unit</i> Value | Expected <i>expr</i> Format |
|--------------------|-----------------------------|
| MICROSECOND | MICROSECONDS |
| SECOND | SECONDS |
| MINUTE | MINUTES |
| hour | HOURS |
| DAY | DAYS |
| WEEK | WEEKS |
| MONTH | MONTHS |
| QUARTER | QUARTERS |
| YEAR | YEARS |
| SECOND_MICROSECOND | 'SECONDS.MICROSECONDS' |

| <i>unit</i> Value | Expected <i>expr</i> Format |
|--------------------|--|
| MINUTE_MICROSECOND | 'MINUTES:SECONDS.MICROSECONDS' |
| MINUTE_SECOND | 'MINUTES:SECONDS' |
| HOURL_MICROSECOND | 'HOURS:MINUTES:SECONDS.MICROSECONDS' |
| HOURL_SECOND | 'HOURS:MINUTES:SECONDS' |
| HOURL_MINUTE | 'HOURS:MINUTES' |
| DAY_MICROSECOND | 'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS' |
| DAY_SECOND | 'DAYS HOURS:MINUTES:SECONDS' |
| DAY_MINUTE | 'DAYS HOURS:MINUTES' |
| DAY_HOUR | 'DAYS HOURS' |
| YEAR_MONTH | 'YEARS-MONTHS' |

MySQL permits any punctuation delimiter in the *expr* format. Those shown in the table are the suggested delimiters.

Temporal intervals are used for certain functions, such as `DATE_ADD()` and `DATE_SUB()`:

```
mysql> SELECT DATE_ADD('2018-05-01',INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01',INTERVAL 1 YEAR);
-> '2017-05-01'
mysql> SELECT DATE_ADD('2020-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '2021-01-01 00:00:00'
mysql> SELECT DATE_ADD('2018-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '2019-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00',
-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1899-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
-> INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

Temporal arithmetic also can be performed in expressions using `INTERVAL` together with the `+` or `-` operator:

```
date + INTERVAL expr unit
date - INTERVAL expr unit
```

`INTERVAL expr unit` is permitted on either side of the `+` operator if the expression on the other side is a date or datetime value. For the `-` operator, `INTERVAL expr unit` is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```
mysql> SELECT '2018-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2019-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2018-12-31';
-> '2019-01-01'
mysql> SELECT '2025-01-01' - INTERVAL 1 SECOND;
-> '2024-12-31 23:59:59'
```

The `EXTRACT()` function uses the same kinds of *unit* specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic:

```
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
```

Temporal intervals can be used in `CREATE EVENT` statements:

```
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the `unit` keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a `unit` of `DAY_SECOND`, the value of `expr` is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10' DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10' MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

`expr` is treated as a string, so be careful if you specify a nonstring value with `INTERVAL`. For example, with an interval specifier of `HOURL_MINUTE`, `'6/4'` is treated as 6 hours, four minutes, whereas `6/4` evaluates to `1.5000` and is treated as 1 hour, 5000 minutes:

```
mysql> SELECT '6/4', 6/4;
-> 1.5000
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL '6/4' HOUR_MINUTE);
-> '2019-01-01 06:04:00'
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL 6/4 HOUR_MINUTE);
-> '2019-01-04 12:20:00'
```

To ensure interpretation of the interval value as you expect, a `CAST()` operation may be used. To treat `6/4` as 1 hour, 5 minutes, cast it to a `DECIMAL` value with a single fractional digit:

```
mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5
mysql> SELECT DATE_ADD('1970-01-01 12:00:00',
-> INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'
```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 DAY);
-> '2023-01-02'
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 HOUR);
-> '2023-01-01 01:00:00'
```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```
mysql> SELECT DATE_ADD('2019-01-30', INTERVAL 1 MONTH);
-> '2019-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2016-07-00'` or badly malformed dates:

```
mysql> SELECT DATE_ADD('2016-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL
```

9.6 Comment Syntax

MySQL Server supports three comment styles:

- From a # character to the end of the line.
- From a -- sequence to the end of the line. In MySQL, the -- (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in [Section 1.7.2.4, "--' as the Start of a Comment"](#).
- From a /* sequence to the following */ sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```
mysql> SELECT 1+1;      # This comment continues to the end of line
mysql> SELECT 1+1;      -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+
/*
this is a
multiple-line comment
*/
1;
```

Nested comments are not supported. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports certain variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the [STRAIGHT_JOIN](#) keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the ! character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The [KEY_BLOCK_SIZE](#) keyword in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.) For information about differences between the server and `mysql` client parsers, see [Section 4.5.1.6, "mysql Client Tips"](#).

Comments in `/*!12345 ... */` format are not stored on the server. If this format is used to comment stored programs, the comments are not retained in the program body.

The use of short-form `mysql` commands such as `\C` within multiple-line `/* ... */` comments is not supported.

| 10.16 MySQL Server Locale Support | 1082 |

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. You can specify character sets at the server, database, table, and column level.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.
- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.
- Selecting the language for error messages.
- Selecting the locale for day and month names.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see [Section 10.5, “Configuring Application Character Set and Collation”](#), and [Section 10.4, “Connection Character Sets and Collations”](#).

10.1 Character Sets and Collations in General

A *character set* is a set of symbols and encodings. A *collation* is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: `A`, `B`, `a`, `b`. We give each letter a number: `A` = 0, `B` = 1, `a` = 2, `b` = 3. The letter `A` is a symbol, the number 0 is the *encoding* for `A`, and the combination of all four letters and their encodings is a *character set*.

Suppose that we want to compare two string values, `A` and `B`. The simplest way to do this is to look at the encodings: 0 for `A` and 1 for `B`. Because 0 is less than 1, we say `A` is less than `B`. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a *binary* collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters `a` and `b` as equivalent to `A` and `B`; (2) then compare the encodings. We call this a *case-insensitive* collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just `A` and `B` but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with

many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German ö), and for multiple-character mappings (such as the rule that ö = oe in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets.
- Compare strings using a variety of collations.
- Mix strings with different character sets or collations in the same server, the same database, or even the same table.
- Enable specification of character set and collation at any level.

To use these features effectively, you must know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

10.2 Character Sets and Collations in MySQL

MySQL Server supports multiple character sets. To display the available character sets, use the `INFORMATION_SCHEMA.CHARACTER_SETS` table or the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see [Section 10.10, “Supported Character Sets and Collations”](#).

```
mysql> SHOW CHARACTER SET;
```

| Charset | Description | Default collation | Maxlen |
|---------|-----------------------------|--------------------|--------|
| big5 | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| ... | | | |
| latin1 | cp1252 West European | latin1_swedish_ci | 1 |
| latin2 | ISO 8859-2 Central European | latin2_general_ci | 1 |
| ... | | | |
| utf8 | UTF-8 Unicode | utf8_general_ci | 3 |
| ucs2 | UCS-2 Unicode | ucs2_general_ci | 2 |
| ... | | | |
| utf8mb4 | UTF-8 Unicode | utf8mb4_general_ci | 4 |
| ... | | | |
| binary | Binary pseudo charset | binary | 1 |
| ... | | | |

By default, the `SHOW CHARACTER SET` statement displays all available character sets. It takes an optional `LIKE` or `WHERE` clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

| Charset | Description | Default collation | Maxlen |
|---------|-----------------------------|-------------------|--------|
| latin1 | cp1252 West European | latin1_swedish_ci | 1 |
| latin2 | ISO 8859-2 Central European | latin2_general_ci | 1 |
| latin5 | ISO 8859-9 Turkish | latin5_turkish_ci | 1 |
| latin7 | ISO 8859-13 Baltic | latin7_general_ci | 1 |

A given character set always has at least one collation, and most character sets have several. To list the display collations for a character set, use the `INFORMATION_SCHEMA.COLLATIONS` table or the `SHOW COLLATION` statement.

By default, the `SHOW COLLATION` statement displays all available collations. It takes an optional `LIKE` or `WHERE` clause that indicates which collation names to display. For example, to see the collations for the default character set, `latin1` (cp1252 West European), use this statement:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
```

| Collation | Charset | Id | Default | Compiled | Sortlen |
|-------------------|---------|----|---------|----------|---------|
| latin1_german1_ci | latin1 | 5 | | Yes | 1 |
| latin1_swedish_ci | latin1 | 8 | Yes | Yes | 1 |
| latin1_danish_ci | latin1 | 15 | | Yes | 1 |
| latin1_german2_ci | latin1 | 31 | | Yes | 2 |
| latin1_bin | latin1 | 47 | | Yes | 1 |
| latin1_general_ci | latin1 | 48 | | Yes | 1 |
| latin1_general_cs | latin1 | 49 | | Yes | 1 |
| latin1_spanish_ci | latin1 | 94 | | Yes | 1 |

The `latin1` collations have the following meanings.

| Collation | Meaning |
|--------------------------------|---|
| <code>latin1_bin</code> | Binary according to <code>latin1</code> encoding |
| <code>latin1_danish_ci</code> | Danish/Norwegian |
| <code>latin1_general_ci</code> | Multilingual (Western European) |
| <code>latin1_general_cs</code> | Multilingual (ISO Western European), case-sensitive |
| <code>latin1_german1_ci</code> | German DIN-1 (dictionary order) |
| <code>latin1_german2_ci</code> | German DIN-2 (phone book order) |
| <code>latin1_spanish_ci</code> | Modern Spanish |
| <code>latin1_swedish_ci</code> | Swedish/Finnish |

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has a *default collation*. For example, the default collations for `latin1` and `utf8` are `latin1_swedish_ci` and `utf8_general_ci`, respectively. The `INFORMATION_SCHEMA.CHARACTER_SETS` table and the `SHOW CHARACTER SET` statement indicate the default collation for each character set. The `INFORMATION_SCHEMA.COLLATIONS` table and the `SHOW COLLATION` statement have a column that indicates for each collation whether it is the default for its character set (`Yes` if so, empty if not).
- Collation names start with the name of the character set with which they are associated, generally followed by one or more suffixes indicating other collation characteristics. For additional information about naming conventions, see [Section 10.3.1, “Collation Naming Conventions”](#).

When a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing an inappropriate collation, perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

10.2.1 Character Set Repertoire

The *repertoire* of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only characters in the Unicode range `U+0000` to `U+007F`.
- **UNICODE**: The expression can contain characters in the Unicode range `U+0000` to `U+10FFFF`. This includes characters in the Basic Multilingual Plane (BMP) range (`U+0000` to `U+FFFF`) and supplementary characters outside the BMP range (`U+10000` to `U+10FFFF`).

The `ASCII` range is a subset of `UNICODE` range, so a string with `ASCII` repertoire can be converted safely without loss of information to the character set of any string with `UNICODE` repertoire or to a

character set that is a superset of [ASCII](#). (All MySQL character sets are supersets of [ASCII](#) with the exception of [swe7](#), which reuses some punctuation characters for Swedish accented characters.) The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an “illegal mix of collations” error.

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

- The repertoire for a string constant depends on string content and may differ from the repertoire of the string character set. Consider these statements:

```
SET NAMES utf8; SELECT 'abc';
SELECT _utf8'def';
SELECT N'MySQL';
```

Although the character set is [utf8](#) in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is [ASCII](#) rather than [UNICODE](#).

- A column having the [ascii](#) character set has [ASCII](#) repertoire because of its character set. In the following table, [c1](#) has [ASCII](#) repertoire:

```
CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
```

The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

```
CREATE TABLE t1 (
  c1 CHAR(1) CHARACTER SET latin1,
  c2 CHAR(1) CHARACTER SET ascii
);
INSERT INTO t1 VALUES ('a','b');
SELECT CONCAT(c1,c2) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (ascii_general_ci,IMPLICIT) for operation 'concat'
```

Using repertoire, subset to superset ([ascii](#) to [latin1](#)) conversion can occur and a result is returned:

```
+-----+
| CONCAT(c1,c2) |
+-----+
| ab           |
+-----+
```

- Functions with one string argument inherit the repertoire of their argument. The result of [UPPER\(_utf8'abc'\)](#) has [ASCII](#) repertoire because its argument has [ASCII](#) repertoire.
- For functions that return a string but do not have string arguments and use [character_set_connection](#) as the result character set, the result repertoire is [ASCII](#) if [character_set_connection](#) is [ascii](#), and [UNICODE](#) otherwise:

```
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:

```
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1,'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE)
```

```
and (latin1_swedish_ci,IMPLICIT) for operation 'concat'
```

With repertoire, a result is returned:

```
+-----+
| CONCAT(FORMAT(a, 4), b) |
+-----+
| 1.0000b                 |
+-----+
```

- Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire ([UNICODE](#) is wider than [ASCII](#)). Consider the following `CONCAT()` calls:

```
CONCAT(_ucs2 X'0041', _ucs2 X'0042')
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')
```

For the first call, the repertoire is [ASCII](#) because both arguments are within the range of the `ascii` character set. For the second call, the repertoire is [UNICODE](#) because the second argument is outside the `ascii` character set range.

- The repertoire for function return values is determined based only on the repertoire of the arguments that affect the result's character set and collation.

```
IF(column1 < column2, 'smaller', 'greater')
```

The result repertoire is [ASCII](#) because the two string arguments (the second argument and the third argument) both have [ASCII](#) repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

10.2.2 UTF-8 for Metadata

Metadata is “the data about the data.” Anything that *describes* the database—as opposed to being the *contents* of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from `SHOW` are metadata. This is also true of the contents of tables in `INFORMATION_SCHEMA` because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, neither the `SHOW` statements nor `SELECT` statements for tables in `INFORMATION_SCHEMA` would work properly because different rows in the same column of the results of these operations would be in different character sets.
- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the `USER()`, `CURRENT_USER()`, `SESSION_USER()`, `SYSTEM_USER()`, `DATABASE()`, and `VERSION()` functions have the UTF-8 character set by default.

The server sets the `character_set_system` system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_system | utf8 |
+-----+-----+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` system variable, which has a default value of `utf8`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` and other related system variables. (See [Section 10.4, “Connection Character Sets and Collations”](#).) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If `character_set_results` is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system`).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see [Section 10.8.4, “Collation Coercibility in Expressions”](#).

10.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` can be used as a synonym for `CHARACTER SET`.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about character set-related issues in client/server communication, see [Section 10.4, “Connection Character Sets and Collations”](#).

10.3.1 Collation Naming Conventions

MySQL collation names follow these conventions:

- A collation name starts with the name of the character set with which it is associated, generally followed by one or more suffixes indicating other collation characteristics. For example, `utf8_general_ci` and `latin1_swedish_ci` are collations for the `utf8` and `latin1` character

sets, respectively. The `binary` character set has a single collation, also named `binary`, with no suffixes.

- A language-specific collation includes a language name. For example, `utf8_turkish_ci` and `utf8_hungarian_ci` sort characters for the `utf8` character set using the rules of Turkish and Hungarian, respectively.
- Collation suffixes indicate whether a collation is case-sensitive, accent-sensitive, or kana-sensitive (or some combination thereof), or binary. The following table shows the suffixes used to indicate these characteristics.

Table 10.1 Collation Suffix Meanings

| Suffix | Meaning |
|-------------------|--------------------|
| <code>_ai</code> | Accent-insensitive |
| <code>_as</code> | Accent-sensitive |
| <code>_ci</code> | Case-insensitive |
| <code>_cs</code> | Case-sensitive |
| <code>_bin</code> | Binary |

For nonbinary collation names that do not specify accent sensitivity, it is determined by case sensitivity. If a collation name does not contain `_ai` or `_as`, `_ci` in the name implies `_ai` and `_cs` in the name implies `_as`. For example, `latin1_general_ci` is explicitly case-insensitive and implicitly accent-insensitive, and `latin1_general_cs` is explicitly case-sensitive and implicitly accent-sensitive.

For the `binary` collation of the `binary` character set, comparisons are based on numeric byte values. For the `_bin` collation of a nonbinary character set, comparisons are based on numeric character code values, which differ from byte values for multibyte characters. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 10.8.5, “The binary Collation Compared to `_bin` Collations”](#).

- For Unicode character sets, the `xxx_general_mysql500_ci` collations preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

10.3.2 Server Character Set and Collation

MySQL Server has a server character set and a server collation. These can be set at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` for the character set. Along with it, you can add `--collation-server` for the collation. If you don't specify a character set, that is the same as saying `--character-set-server=latin1`. If you specify only a character set (for example, `latin1`) but not a collation, that is the same as saying `--character-set-server=latin1 --collation-server=latin1_swedish_ci` because `latin1_swedish_ci` is the default collation for `latin1`. Therefore, the following three commands all have the same effect:

```
mysqld
mysqld --character-set-server=latin1
mysqld --character-set-server=latin1 \
--collation-server=latin1_swedish_ci
```

One way to change the settings is by recompiling. To change the default server character set and collation when building from sources, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` options for `CMake`. For example:

```
cmake . -DDEFAULT_CHARSET=latin1
```

Or:

```
cmake . -DDEFAULT_CHARSET=latin1 \
-DDEFAULT_COLLATION=latin1_german1_ci
```

Both `mysqld` and `CMake` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in `CREATE DATABASE` statements. They have no other purpose.

The current server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

10.3.3 Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

All database options are stored in a text file named `db.opt` that can be found in the database directory.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used.
- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.
- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the server character set and server collation are used.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

To see the default character set and collation for a given database, use these statements:

```
USE db_name;
```

```
SELECT @@character_set_database, @@collation_database;
```

Alternatively, to display the values without changing the default database:

```
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```

The database character set and collation affect these aspects of server operation:

- For `CREATE TABLE` statements, the database character set and collation are used as default values for table definitions if the table character set and collation are not specified. To override this, provide explicit `CHARACTER SET` and `COLLATE` table options.
- For `LOAD DATA` statements that include no `CHARACTER SET` clause, the server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. To override this, provide an explicit `CHARACTER SET` clause.
- For stored routines (procedures and functions), the database character set and collation in effect at routine creation time are used as the character set and collation of character data parameters for which the declaration includes no `CHARACTER SET` or a `COLLATE` attribute. To override this, provide `CHARACTER SET` and `COLLATE` explicitly.

10.3.4 Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
  [[DEFAULT] CHARACTER SET charset_name]
  [[COLLATE collation_name]]

ALTER TABLE tbl_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[COLLATE collation_name]]
```

Example:

```
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used.
- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.
- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

10.3.5 Column Character Set and Collation

Every “character” column (that is, a column of type `CHAR`, `VARCHAR`, a `TEXT` type, or any synonym) has a column character set and a column collation. Column definition syntax for `CREATE TABLE` and `ALTER TABLE` has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
  [CHARACTER SET charset_name]
  [COLLATE collation_name]
```

These clauses can also be used for [ENUM](#) and [SET](#) columns:

```
col_name {ENUM | SET} (val_list)
  [CHARACTER SET charset_name]
  [COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1
(
  coll VARCHAR(5)
    CHARACTER SET latin1
    COLLATE latin1_german1_ci
);

ALTER TABLE t1 MODIFY
  coll VARCHAR(5)
    CHARACTER SET latin1
    COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- If both [CHARACTER SET charset_name](#) and [COLLATE collation_name](#) are specified, character set [charset_name](#) and collation [collation_name](#) are used.

```
CREATE TABLE t1
(
  coll CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set and collation are specified for the column, so they are used. The column has character set [utf8](#) and collation [utf8_unicode_ci](#).

- If [CHARACTER SET charset_name](#) is specified without [COLLATE](#), character set [charset_name](#) and its default collation are used.

```
CREATE TABLE t1
(
  coll CHAR(10) CHARACTER SET utf8
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set [utf8](#) and the default collation for [utf8](#), which is [utf8_general_ci](#). To see the default collation for each character set, use the [SHOW CHARACTER SET](#) statement or query the [INFORMATION_SCHEMA.CHARACTER_SETS](#) table.

- If [COLLATE collation_name](#) is specified without [CHARACTER SET](#), the character set associated with [collation_name](#) and collation [collation_name](#) are used.

```
CREATE TABLE t1
(
  coll CHAR(10) COLLATE utf8_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The collation is specified for the column, but the character set is not. The column has collation [utf8_polish_ci](#) and the character set is the one associated with the collation, which is [utf8](#).

- Otherwise (neither [CHARACTER SET](#) nor [COLLATE](#) is specified), the table character set and collation are used.

```
CREATE TABLE t1
(
  coll CHAR(10)
```

```
) CHARACTER SET latin1 COLLATE latin1_bin;
```

Neither the character set nor collation is specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

If you use `ALTER TABLE` to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

10.3.6 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

For the simple statement `SELECT 'string'`, the string has the connection default character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set `charset_name`.” An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal. See [Section 10.3.8, “Character Set Introducers”](#).

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8'abc' COLLATE utf8_danish_ci;
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

MySQL determines the character set and collation of a character string literal in the following manner:

- If both `_charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.
- If `_charset_name` is specified but `COLLATE` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `_charset_name` is not specified but `COLLATE collation_name` is specified, the connection default character set given by the `character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
- Otherwise (neither `_charset_name` nor `COLLATE collation_name` is specified), the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.

Examples:

- A nonbinary string with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
```

- A nonbinary string with `utf8` character set and its default collation (that is, `utf8_general_ci`):

```
SELECT _utf8'Müller';
```

- A binary string with `binary` character set and its default collation (that is, `binary`):

```
SELECT _binary'Müller';
```

- A nonbinary string with the connection default character set and `utf8_general_ci` collation (fails if the connection character set is not `utf8`):

```
SELECT 'Müller' COLLATE utf8_general_ci;
```

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

An introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`.

The following examples show that escape processing occurs using `character_set_connection` even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection`, as discussed in [Section 10.4, “Connection Character Sets and Collations”](#)), and display the resulting strings using the `HEX()` function so that the exact string contents can be seen.

Example 1:

```
mysql> SET NAMES latin1;
mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
+-----+-----+
| HEX('à\n') | HEX(_sjis'à\n') |
+-----+-----+
| E00A      | E00A              |
+-----+-----+
```

Here, `à` (hexadecimal value `E0`) is followed by `\n`, the escape sequence for newline. The escape sequence is interpreted using the `character_set_connection` value of `latin1` to produce a literal newline (hexadecimal value `0A`). This happens even for the second string. That is, the `_sjis` introducer does not affect the parser's escape processing.

Example 2:

```
mysql> SET NAMES sjis;
mysql> SELECT HEX('à\n'), HEX(_latin1'à\n');
+-----+-----+
| HEX('à\n') | HEX(_latin1'à\n') |
+-----+-----+
| E05C6E     | E05C6E             |
+-----+-----+
```

Here, `character_set_connection` is `sjis`, a character set in which the sequence of `à` followed by `\` (hexadecimal values `05` and `5C`) is a valid multibyte character. Hence, the first two bytes of the string are interpreted as a single `sjis` character, and the `\` is not interpreted as an escape character. The following `n` (hexadecimal value `6E`) is not interpreted as part of an escape sequence. This is true even for the second string; the `_latin1` introducer does not affect escape processing.

10.3.7 The National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
```

```
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NVARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

10.3.8 Character Set Introducers

A character string literal, hexadecimal literal, or bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] literal [COLLATE collation_name]
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set `charset_name`.” An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal.

For character string literals, space between the introducer and the string is permitted but optional.

For character set literals, an introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`. For additional discussion and examples, see [Section 10.3.6, “Character String Literal Character Set and Collation”](#).

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8'abc' COLLATE utf8_danish_ci;

SELECT _latin1 X'4D7953514C';
SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;

SELECT _latin1 b'1000001';
SELECT _utf8 0b1000001 COLLATE utf8_danish_ci;
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

Character string literals can be designated as binary strings by using the `_binary` introducer. Hexadecimal literals and bit-value literals are binary strings by default, so `_binary` is permitted, but unnecessary.

MySQL determines the character set and collation of a character string literal, hexadecimal literal, or bit-value literal in the following manner:

- If both `_charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.

- If `_charset_name` is specified but `COLLATE` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `_charset_name` is not specified but `COLLATE collation_name` is specified:
 - For a character string literal, the connection default character set given by the `character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
 - For a hexadecimal literal or bit-value literal, the only permitted collation is `binary` because these types of literals are binary strings by default.
- Otherwise (neither `_charset_name` nor `COLLATE collation_name` is specified):
 - For a character string literal, the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.
 - For a hexadecimal literal or bit-value literal, the character set and collation are `binary`.

Examples:

- Nonbinary strings with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
SELECT _latin1 X'0A0D' COLLATE latin1_german1_ci;
SELECT _latin1 b'0110' COLLATE latin1_german1_ci;
```

- Nonbinary strings with `utf8` character set and its default collation (that is, `utf8_general_ci`):

```
SELECT _utf8'Müller';
SELECT _utf8 X'0A0D';
SELECT _utf8 b'0110';
```

- Binary strings with `binary` character set and its default collation (that is, `binary`):

```
SELECT _binary'Müller';
SELECT X'0A0D';
SELECT b'0110';
```

The hexadecimal literal and bit-value literal need no introducer because they are binary strings by default.

- A nonbinary string with the connection default character set and `utf8_general_ci` collation (fails if the connection character set is not `utf8`):

```
SELECT 'Müller' COLLATE utf8_general_ci;
```

This construction (`COLLATE` only) does not work for hexadecimal literals or bit literals because their character set is `binary` no matter the connection character set, and `binary` is not compatible with the `utf8_general_ci` collation. The only permitted `COLLATE` clause in the absence of an introducer is `COLLATE binary`.

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

10.3.9 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

Example 1: Table and Column Definition

```
CREATE TABLE t1
(
```

```
c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

Example 2: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

Example 3: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

Example 4: Database, Table, and Column Definition

```
CREATE DATABASE d1
  DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
(
  c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

10.3.10 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

10.4 Connection Character Sets and Collations

A “connection” is what a client program makes when it connects to the server, to begin a session within which it interacts with the server. The client sends SQL statements, such as queries, over the session connection. The server sends responses, such as result sets or error messages, over the connection back to the client.

- [Connection Character Set and Collation System Variables](#)
- [Impermissible Client Character Sets](#)
- [Client Program Connection Character Set Configuration](#)
- [SQL Statements for Connection Character Set Configuration](#)

- [Connection Character Set Error Handling](#)

Connection Character Set and Collation System Variables

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The `character_set_server` and `collation_server` system variables indicate the server character set and collation. See [Section 10.3.2, “Server Character Set and Collation”](#).
- The `character_set_database` and `collation_database` system variables indicate the character set and collation of the default database. See [Section 10.3.3, “Database Character Set and Collation”](#).

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has session-specific connection-related character set and collation system variables. These session system variable values are initialized at connect time, but can be changed within the session.

Several questions about character set and collation handling for client connections can be answered in terms of system variables:

- What character set are statements in when they leave the client?

The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

Note

Some character sets cannot be used as the client character set. See [Impermissible Client Character Sets](#).

- What character set should the server translate statements to after receiving them?

To determine this, the server uses the `character_set_connection` and `collation_connection` system variables:

- The server converts statements sent by the client from `character_set_client` to `character_set_connection`. Exception: For string literals that have an introducer such as `_utf8mb4` or `_latin2`, the introducer determines the character set. See [Section 10.3.8, “Character Set Introdurers”](#).
- `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see [Section 10.8.4, “Collation Coercibility in Expressions”](#)).
- What character set should the server translate query results to before shipping them back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

To tell the server to perform no conversion of result sets or error messages, set `character_set_results` to `NULL` or `binary`:

```
SET character_set_results = NULL;
SET character_set_results = binary;
```

For more information about character sets and error messages, see [Section 10.6, “Error Message Character Set”](#).

To see the values of the character set and collation system variables that apply to the current session, use this statement:

```
SELECT * FROM INFORMATION_SCHEMA.SESSION_VARIABLES
WHERE VARIABLE_NAME IN (
'character_set_client', 'character_set_connection',
'character_set_results', 'collation_connection'
) ORDER BY VARIABLE_NAME;
```

The following simpler statements also display the connection variables, but include other related variables as well. They can be useful to see *all* character set and collation system variables:

```
SHOW SESSION VARIABLES LIKE 'character\_set\_%';
SHOW SESSION VARIABLES LIKE 'collation\_%';
```

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings *for each connection to the server*.

Impermissible Client Character Sets

The `character_set_client` system variable cannot be set to certain character sets:

```
ucs2
utf16
utf32
```

Attempting to use any of those character sets as the client character set produces an error:

```
mysql> SET character_set_client = 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client'
can't be set to the value of 'ucs2'
```

The same error occurs if any of those character sets are used in the following contexts, all of which result in an attempt to set `character_set_client` to the named character set:

- The `--default-character-set=charset_name` command option used by MySQL client programs such as `mysql` and `mysqladmin`.
- The `SET NAMES 'charset_name'` statement.
- The `SET CHARACTER SET 'charset_name'` statement.

Client Program Connection Character Set Configuration

When a client connects to the server, it indicates which character set it wants to use for communication with the server. (Actually, the client indicates the default collation for that character set, from which the server can determine the character set.) The server uses this information to set the `character_set_client`, `character_set_results`, `character_set_connection` system variables to the character set, and `collation_connection` to the character set default collation. In effect, the server performs the equivalent of a `SET NAMES` operation.

If the server does not support the requested character set or collation, it falls back to using the server character set and collation to configure the connection. For additional detail about this fallback behavior, see [Connection Character Set Error Handling](#).

The `mysql`, `mysqladmin`, `mysqlcheck`, `mysqlimport`, and `mysqlshow` client programs determine the default character set to use as follows:

- In the absence of other information, each client uses the compiled-in default character set, usually `latin1`.
- Each client can autodetect which character set to use based on the operating system setting, such as the value of the `LANG` or `LC_ALL` locale environment variable on Unix systems or the code page

setting on Windows systems. For systems on which the locale is available from the OS, the client uses it to set the default character set rather than using the compiled-in default. For example, setting `LANG` to `ru_RU.KOI8-R` causes the `koi8r` character set to be used. Thus, users can configure the locale in their environment for use by MySQL clients.

The OS character set is mapped to the closest MySQL character set if there is no exact match. If the client does not support the matching character set, it uses the compiled-in default. For example, `ucs2` is not supported as a connection character set, so it maps to the compiled-in default.

C applications can use character set autodetection based on the OS setting by invoking `mysql_options()` as follows before connecting to the server:

```
mysql_options(mysql,
              MYSQL_SET_CHARSET_NAME,
              MYSQL_AUTODETECT_CHARSET_NAME);
```

- Each client supports a `--default-character-set` option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

Note

Some character sets cannot be used as the client character set. Attempting to use them with `--default-character-set` produces an error. See [Impermissible Client Character Sets](#).

Note

Before MySQL 5.5, in the absence of other information, the MySQL client programs used the compiled-in default character set, usually `latin1`. An implication of this difference is that if your environment is configured to use a non-`latin1` locale, MySQL client programs will use a different connection character set than previously, as though you had issued an implicit `SET NAMES` statement. If the previous behavior is required, start the client with the `--default-character-set=latin1` option.

With the `mysql` client, to use a character set different from the default, you could explicitly execute a `SET NAMES` statement every time you connect to the server (see [Client Program Connection Character Set Configuration](#)). To accomplish the same result more easily, specify the character set in your option file. For example, the following option file setting changes the three connection-related character set system variables set to `koi8r` each time you invoke `mysql`:

```
[mysql]
default-character-set=koi8r
```

If you are using the `mysql` client with auto-reconnect enabled (which is not recommended), it is preferable to use the `charset` command rather than `SET NAMES`. For example:

```
mysql> charset koi8r
Charset changed
```

The `charset` command issues a `SET NAMES` statement, and also changes the default character set that `mysql` uses when it reconnects after the connection has dropped.

When configuring client programs, you must also consider the environment within which they execute. See [Section 10.5, "Configuring Application Character Set and Collation"](#).

SQL Statements for Connection Character Set Configuration

After a connection has been established, clients can change the character set and collation system variables for the current session. These variables can be changed individually using `SET` statements, but two more convenient statements affect the connection-related character set system variables as a group:

- `SET NAMES 'charset_name' [COLLATE 'collation_name']`

`SET NAMES` indicates what character set the client will use to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set `cp1251`.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement that produces a result set.)

A `SET NAMES 'charset_name'` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET character_set_connection = charset_name;
```

Setting `character_set_connection` to `charset_name` also implicitly sets `collation_connection` to the default collation for `charset_name`. It is unnecessary to set that collation explicitly. To specify a particular collation to use for `collation_connection`, add a `COLLATE` clause:

```
SET NAMES 'charset_name' COLLATE 'collation_name'
```

- `SET CHARACTER SET 'charset_name'`

`SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` and `collation_connection` to `character_set_database` and `collation_database` (which, as mentioned previously, indicate the character set and collation of the default database).

A `SET CHARACTER SET charset_name` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET collation_connection = @@collation_database;
```

Setting `collation_connection` also implicitly sets `character_set_connection` to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is unnecessary to set `character_set_connection` explicitly.

Note

Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` or `SET CHARACTER SET` produces an error. See [Impermissible Client Character Sets](#).

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET 'latin1'` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy for characters that are not in both character sets.

Connection Character Set Error Handling

Attempts to use an inappropriate connection character set or collation can produce an error, or cause the server to fall back to its default character set and collation for a given connection. This section describes problems that can occur when configuring the connection character set. These problems can occur when establishing a connection or when changing the character set within an established connection.

- [Connect-Time Error Handling](#)
- [Runtime Error Handling](#)

Connect-Time Error Handling

Some character sets cannot be used as the client character set; see [Impermissible Client Character Sets](#). If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```
shell> mysql --default-character-set=ucs2
ERROR 1231 (42000): Variable 'character_set_client' can't be set to
the value of 'ucs2'
```

If you specify a character set that the client does not recognize, it produces an error:

```
shell> mysql --default-character-set=bogus
mysql: Character set 'bogus' is not a compiled character set and is
not specified in the '/usr/local/mysql/share/charsets/Index.xml' file
ERROR 2019 (HY000): Can't initialize character set bogus
(path: /usr/local/mysql/share/charsets/)
```

If you specify a character set that the client recognizes but the server does not, the server falls back to its default character set and collation. Suppose that the server is configured to use `latin1` and `latin1_swedish_ci` as its defaults, and that it does not recognize `gb18030` as a valid character set. A client that specifies `--default-character-set=gb18030` is able to connect to the server, but the resulting character set is not what the client wants:

```
mysql> SHOW SESSION VARIABLES LIKE 'character\_set\_%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| character_set_client   | latin1 |
| character_set_connection | latin1 |
| ...                    | ...   |
| character_set_results  | latin1 |
| ...                    | ...   |
+-----+-----+
mysql> SHOW SESSION VARIABLES LIKE 'collation_connection';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| collation_connection   | latin1_swedish_ci |
+-----+-----+
```

You can see that the connection system variables have been set to reflect a character set and collation of `latin1` and `latin1_swedish_ci`. This occurs because the server cannot satisfy the client character set request and falls back to its defaults.

In this case, the client cannot use the character set that it wants because the server does not support it. The client must either be willing to use a different character set, or connect to a different server that supports the desired character set.

The same problem occurs in a more subtle context: When the client tells the server to use a character set that the server recognizes, but the default collation for that character set on the client side is not known on the server side. This occurs, for example, when a MySQL 8.0 client wants to connect to a MySQL 5.7 server using `utf8mb4` as the client character set. A client that specifies `--default-character-set=utf8mb4` is able to connect to the server. However, as in the previous example, the server falls back to its default character set and collation, not what the client requested:

```
mysql> SHOW SESSION VARIABLES LIKE 'character\_set\_%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| character_set_client   | latin1 |
| character_set_connection | latin1 |
| ...                    | ...   |
| character_set_results  | latin1 |
| ...                    | ...   |
+-----+-----+
mysql> SHOW SESSION VARIABLES LIKE 'collation_connection';
```

| Variable_name | Value |
|----------------------|-------------------|
| collation_connection | latin1_swedish_ci |

Why does this occur? After all, `utf8mb4` is known to the 8.0 client and the 5.7 server, so both of them recognize it. To understand this behavior, it is necessary to understand that when the client tells the server which character set it wants to use, it really tells the server the default collation for that character set. Therefore, the aforementioned behavior occurs due to a combination of factors:

- The default collation for `utf8mb4` differs between MySQL 5.7 and 8.0 (`utf8mb4_general_ci` for 5.7, `utf8mb4_0900_ai_ci` for 8.0).
- When the 8.0 client requests a character set of `utf8mb4`, what it sends to the server is the default 8.0 `utf8mb4` collation; that is, the `utf8mb4_0900_ai_ci`.
- `utf8mb4_0900_ai_ci` is implemented only as of MySQL 8.0, so the 5.7 server does not recognize it.
- Because the 5.7 server does not recognize `utf8mb4_0900_ai_ci`, it cannot satisfy the client character set request, and falls back to its default character set and collation (`latin1` and `latin1_swedish_ci`).

In this case, the client can still use `utf8mb4` by issuing a `SET NAMES 'utf8mb4'` statement after connecting. The resulting collation is the 5.7 default `utf8mb4` collation; that is, `utf8mb4_general_ci`. If the client additionally wants a collation of `utf8mb4_0900_ai_ci`, it cannot achieve that because the server does not recognize that collation. The client must either be willing to use a different `utf8mb4` collation, or connect to a server from MySQL 8.0 or higher.

Runtime Error Handling

Within an established connection, the client can request a change of connection character set and collation with `SET NAMES` or `SET CHARACTER SET`.

Some character sets cannot be used as the client character set; see [Impermissible Client Character Sets](#). If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```
mysql> SET NAMES 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client' can't be set to
the value of 'ucs2'
```

If the server does not recognize the character set (or the collation), it produces an error:

```
mysql> SET NAMES 'bogus';
ERROR 1115 (42000): Unknown character set: 'bogus'

mysql> SET NAMES 'utf8mb4' COLLATE 'bogus';
ERROR 1273 (HY000): Unknown collation: 'bogus'
```

Tip

A client that wants to verify whether its requested character set was honored by the server can execute the following statement after connecting and checking that the result is the expected character set:

```
SELECT @@character_set_client;
```

10.5 Configuring Application Character Set and Collation

For applications that store data using the default MySQL character set and collation (`latin1`, `latin1_swedish_ci`), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might use the default of `latin1`, whereas applications that use another database might use `sjis`.
- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.
- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings as the defaults for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the `utf8` character set and `utf8_general_ci` collation in particular contexts as an alternative to the defaults of `latin1` and `latin1_swedish_ci`.

- **Specify character settings per database.** To create a database such that its tables will use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

```
CREATE DATABASE mydb
  CHARACTER SET utf8
  COLLATE utf8_general_ci;
```

Tables created in the database will use `utf8` and `utf8_general_ci` by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'utf8'` statement after connecting. The statement can be used regardless of connection method (the `mysql` client, PHP scripts, and so forth).

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, to connect using `mysql`, you can specify the `--default-character-set=utf8` command-line option to achieve the same effect as `SET NAMES 'utf8'`.

For more information about configuring client connections, see [Section 10.4, “Connection Character Sets and Collations”](#).

Note

If you use `ALTER DATABASE` to change the database default character set or collation, existing stored routines in the database that use those defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).)

- **Specify character settings at server startup.** To select a character set and collation at server startup, use the `--character-set-server` and `--collation-server` options. For example, to specify the options in an option file, include these lines:

```
[mysqld]
character-set-server=utf8
collation-server=utf8_general_ci
```

These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'utf8'"` option to cause `SET NAMES` to be executed automatically for each client that connects. However, this may yield inconsistent results because the `init_connect` value is not executed for users who have the `SUPER` privilege.

- **Specify character settings at MySQL configuration time.** To select a character set and collation if you configure and build MySQL from source, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` CMake options:

```
cmake . -DDEFAULT_CHARSET=utf8 \
-DDEFAULT_COLLATION=utf8_general_ci
```

The resulting server uses `utf8` and `utf8_general_ci` as the default for databases and tables and for client connections. It is unnecessary to use `--character-set-server` and `--collation-server` to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using `SET NAMES` or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. For example, if you will send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the `mysql` client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `<meta>` tag within your `<head>` element:

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

10.6 Error Message Character Set

This section describes how the MySQL server uses character sets for constructing error messages. For information about the language of error messages (rather than the character set), see [Section 10.12, “Setting the Error Message Language”](#). For general information about configuring error logging, see [Section 5.4.2, “The Error Log”](#).

- [Character Set for Error Message Construction](#)
- [Character Set for Error Message Disposition](#)

Character Set for Error Message Construction

The server constructs error messages as follows:

- The message template uses UTF-8 (`utf8mb3`).
- Parameters in the message template are replaced with values that apply to a specific error occurrence:
 - Identifiers such as table or column names use UTF-8 internally so they are copied as is.
 - Character (nonbinary) string values are converted from their character set to UTF-8.
 - Binary string values are copied as is for bytes in the range `0x20` to `0x7E`, and using `\x` hexadecimal encoding for bytes outside that range. For example, if a duplicate-key error occurs for an attempt to insert `0x41CF9F` into a `VARBINARY` unique column, the resulting error message uses UTF-8 with some bytes hexadecimal encoded:

```
Duplicate entry 'A\xC3\x9F' for key 1
```

Character Set for Error Message Disposition

An error message, once constructed, can be written by the server to the error log or sent to clients:

- If the server writes the error message to the error log, it writes it in UTF-8, as constructed, without conversion to another character set.
- If the server sends the error message to a client program, the server converts it from UTF-8 to the character set specified by the `character_set_results` system variable. If `character_set_results` has a value of `NULL` or `binary`, no conversion occurs. No conversion occurs if the variable value is `utf8mb3` or `utf8mb4`, either, because those character sets have a repertoire that includes all UTF-8 characters used in message construction.

If characters cannot be represented in `character_set_results`, some encoding may occur during the conversion. The encoding uses Unicode code point values:

- Characters in the Basic Multilingual Plane (BMP) range (`0x0000` to `0xFFFF`) are written using `\nnnn` notation.
- Characters outside the BMP range (`0x10000` to `0x10FFFF`) are written using `\+nnnnnnn` notation.

Clients can set `character_set_results` to control the character set in which they receive error messages. The variable can be set directly, or indirectly by means such as `SET NAMES`. For more information about `character_set_results`, see [Section 10.4, “Connection Character Sets and Collations”](#).

10.7 Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`. For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type (`BINARY`, `VARBINARY`, `BLOB`), all the values that it contains must be encoded using a single character set (the character set you're converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.
- If the column has a nonbinary data type (`CHAR`, `VARCHAR`, `TEXT`), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `coll` defined as `VARBINARY(50)`. Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `coll` contains binary data representing characters in the `greek` character set, you can convert it as follows:

```
ALTER TABLE t MODIFY coll VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of `BINARY(50)`, you could convert it to `CHAR(50)`, but the resulting values will be padded with `0x00` bytes at the end, which may be undesirable. To remove these bytes, use the `TRIM()` function:

```
UPDATE t SET coll = TRIM(TRAILING 0x00 FROM coll);
```

Suppose that table `t` has a nonbinary column named `coll` defined as `CHAR(50) CHARACTER SET latin1` but you want to convert it to use `utf8` so that you can store values from many languages. The following statement accomplishes this:

```
ALTER TABLE t MODIFY coll CHAR(50) CHARACTER SET utf8;
```

Conversion may be lossy if the column contains characters that are not in both character sets.

A special case occurs if you have old tables from before MySQL 4.1 where a nonbinary column contains values that actually are encoded in a character set different from the server's default character set. For example, an application might have stored `sjis` values in a column, even though MySQL's default character set was different. It is possible to convert the column to use the proper character set but an additional step is required. Suppose that the server's default character set was `latin1` and `coll` is defined as `CHAR(50)` but its contents are `sjis` values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

```
ALTER TABLE t MODIFY coll BLOB;
```

The next step is to convert the column to a nonbinary data type with the proper character set:

```
ALTER TABLE t MODIFY coll CHAR(50) CHARACTER SET sjis;
```

This procedure requires that the table not have been modified already with statements such as `INSERT` or `UPDATE` after an upgrade to MySQL 4.1 or higher. In that case, MySQL would store new values in the column using `latin1`, and the column will contain a mix of `sjis` and `latin1` values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with `ALTER TABLE`. For example, if you specified `NOT NULL` and an explicit `DEFAULT` value, you should also provide them in the `ALTER TABLE` statement. Otherwise, the resulting column definition will not include those attributes.

To convert all character columns in a table, the `ALTER TABLE ... CONVERT TO CHARACTER SET charset` statement may be useful. See [Section 13.1.7, "ALTER TABLE Statement"](#).

10.8 Collation Issues

The following sections discuss various aspects of character set collations.

10.8.1 Using COLLATE in SQL Statements

With the `COLLATE` clause, you can override whatever the default collation is for a comparison. `COLLATE` may be used in various parts of SQL statements. Here are some examples:

- With `ORDER BY`:

```
SELECT k
FROM t1
ORDER BY k COLLATE latin1_german2_ci;
```

- With `AS`:

```
SELECT k COLLATE latin1_german2_ci AS k1
FROM t1
ORDER BY k1;
```

- With `GROUP BY`:

```
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:

```
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With `DISTINCT`:

```
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

- With `WHERE`:

```
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

```
SELECT *
FROM t1
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

- With `HAVING`:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

10.8.2 COLLATE Clause Precedence

The `COLLATE` clause has high precedence (higher than `| |`), so the following two expressions are equivalent:

```
x | | y COLLATE z
x | | (y COLLATE z)
```

10.8.3 Character Set and Collation Compatibility

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

10.8.4 Collation Coercibility in Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `x`:

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, with multiple operands, there can be ambiguity. For example:

```
SELECT x FROM T WHERE x = 'Y';
```

Should the comparison use the collation of the column `x`, or of the string literal `'Y'`? Both `x` and `'Y'` have collations, so which collation takes precedence?

A mix of collations may also occur in contexts other than comparison. For example, a multiple-argument concatenation operation such as `CONCAT(x, 'Y')` combines its arguments to produce a single string. What collation should the result have?

To resolve questions like these, MySQL checks whether the collation of one item can be coerced to the collation of the other. MySQL assigns coercibility values as follows:

- An explicit `COLLATE` clause has a coercibility of 0 (not coercible at all).
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.

- A “system constant” (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- The collation of a numeric or temporal value has a coercibility of 5.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 6.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
 - If both sides are Unicode, or both sides are not Unicode, it is an error.
 - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:

```
SELECT CONCAT(utf8_column, latin1_column) FROM t1;
```

It returns a result that has a character set of `utf8` and the same collation as `utf8_column`. Values of `latin1_column` are automatically converted to `utf8` before concatenating.

- For an operation with operands from the same character set but that mix a `_bin` collation and a `_ci` or `_cs` collation, the `_bin` collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, except that it is for collations rather than data types.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings.

The following table illustrates some applications of the preceding rules.

| Comparison | Collation Used |
|--|---|
| <code>column1 = 'A'</code> | Use collation of <code>column1</code> |
| <code>column1 = 'A' COLLATE x</code> | Use collation of <code>'A' COLLATE x</code> |
| <code>column1 COLLATE x = 'A' COLLATE y</code> | Error |

To determine the coercibility of a string expression, use the `COERCIBILITY()` function (see [Section 12.15, “Information Functions”](#)):

```
mysql> SELECT COERCIBILITY('A' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
mysql> SELECT COERCIBILITY('A');
-> 4
mysql> SELECT COERCIBILITY(1000);
-> 5
```

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument `1` in the expression `CONCAT(1, 'abc')`, the result is a character (nonbinary) string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. See [Section 12.2, “Type Conversion in Expression Evaluation”](#).

10.8.5 The binary Collation Compared to `_bin` Collations

This section describes how the `binary` collation for binary strings compares to `_bin` collations for nonbinary strings.

Binary strings (as stored using the `BINARY`, `VARBINARY`, and `BLOB` data types) have a character set and collation named `binary`. Binary strings are sequences of bytes and the numeric values of those bytes determine comparison and sort order. See [Section 10.10.8, “The Binary Character Set”](#).

Nonbinary strings (as stored using the `CHAR`, `VARCHAR`, and `TEXT` data types) have a character set and collation other than `binary`. A given nonbinary character set can have several collations, each of which defines a particular comparison and sort order for the characters in the set. One of these is the binary collation, indicated by a `_bin` suffix in the collation name. For example, the binary collation for `utf8` and `latin1` is named `utf8_bin` and `latin1_bin`, respectively.

The `binary` collation differs from `_bin` collations in several respects, discussed in the following sections:

- [The Unit for Comparison and Sorting](#)
- [Character Set Conversion](#)
- [Lettercase Conversion](#)
- [Trailing Space Handling in Comparisons](#)
- [Trailing Space Handling for Inserts and Retrievals](#)

The Unit for Comparison and Sorting

Binary strings are sequences of bytes. For the `binary` collation, comparison and sorting are based on numeric byte values. Nonbinary strings are sequences of characters, which might be multibyte. Collations for nonbinary strings define an ordering of the character values for comparison and sorting. For `_bin` collations, this ordering is based on numeric character code values, which is similar to ordering for binary strings except that character code values might be multibyte.

Character Set Conversion

A nonbinary string has a character set and is automatically converted to another character set in many cases, even when the string has a `_bin` collation:

- When assigning column values to another column that has a different character set:

```
UPDATE t1 SET utf8_bin_column=latin1_column;
INSERT INTO t1 (latin1_column) SELECT utf8_bin_column FROM t2;
```

- When assigning column values for `INSERT` or `UPDATE` using a string literal:

```
SET NAMES latin1;
INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');
```

- When sending results from the server to a client:

```
SET NAMES latin1;
SELECT utf8_bin_column FROM t2;
```

For binary string columns, no conversion occurs. For cases similar to those preceding, the string value is copied byte-wise.

Lettercase Conversion

Collations for nonbinary character sets provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for `_bin` collations that ignore lettercase for ordering:

```
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_bin;
mysql> SELECT LOWER('aA'), UPPER('zZ');
```

```

+-----+-----+
| LOWER('aA') | UPPER('zZ') |
+-----+-----+
| aa          | ZZ          |
+-----+-----+

```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must first be converted to a nonbinary string using a character set appropriate for the data stored in the string:

```

mysql> SET NAMES binary;
mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING utf8mb4));
+-----+-----+
| LOWER('aA') | LOWER(CONVERT('aA' USING utf8mb4)) |
+-----+-----+
| aA         | aa          |
+-----+-----+

```

Trailing Space Handling in Comparisons

Nonbinary strings have `PAD SPACE` behavior for all collations, including `_bin` collations. Trailing spaces are insignificant in comparisons:

```

mysql> SET NAMES utf8 COLLATE utf8_bin;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
|           1 |
+-----+

```

For binary strings, all characters are significant in comparisons, including trailing spaces:

```

mysql> SET NAMES binary;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
|           0 |
+-----+

```

Trailing Space Handling for Inserts and Retrievals

`CHAR(N)` columns store nonbinary strings `N` characters long. For inserts, values shorter than `N` characters are extended with spaces. For retrievals, trailing spaces are removed.

`BINARY(N)` columns store binary strings `N` bytes long. For inserts, values shorter than `N` bytes are extended with `0x00` bytes. For retrievals, nothing is removed; a value of the declared length is always returned.

```

mysql> CREATE TABLE t1 (
    a CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin,
    b BINARY(10)
);
mysql> INSERT INTO t1 VALUES ('x','x');
mysql> INSERT INTO t1 VALUES ('x ','x ');
mysql> SELECT a, b, HEX(a), HEX(b) FROM t1;
+-----+-----+-----+-----+
| a    | b          | HEX(a) | HEX(b) |
+-----+-----+-----+-----+
| x    | x          | 78     | 78000000000000000000 |
| x    | x          | 78     | 78200000000000000000 |
+-----+-----+-----+-----+

```

10.8.6 Examples of the Effect of Collation

Example 1: Sorting German Umlauts

Suppose that column `x` in table `T` has these `latin1` column values:

```
Muffler
Müller
MX Systems
MySQL
```

Suppose also that the column values are retrieved using the following statement:

```
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use `ORDER BY` with different collations.

| <code>latin1_swedish_ci</code> | <code>latin1_german1_ci</code> | <code>latin1_german2_ci</code> |
|--------------------------------|--------------------------------|--------------------------------|
| Muffler | Muffler | Müller |
| MX Systems | Müller | Muffler |
| Müller | MX Systems | MX Systems |
| MySQL | MySQL | MySQL |

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the `SELECT` using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```
mysql> SET NAMES utf8;
mysql> CREATE TABLE german1 (
    c CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (
    c CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (
    c CHAR(10)
) CHARACTER SET utf8 COLLATE utf8_unicode_ci;
```

Each table contains two records:

```
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');
```

Two of the above collations have an `A = Ä` equality, and one has no such equality (`latin1_german2_ci`). For that reason, you'll get these results in comparisons:

```
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bar    |
| Bär    |
+-----+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bär    |
+-----+
```

```
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+-----+
| c     |
+-----+
| Bar   |
| Bär   |
+-----+
```

This is not a bug but rather a consequence of the sorting properties of `latin1_german1_ci` and `utf8_unicode_ci` (the sorting shown is done according to the German DIN 5007 standard).

10.8.7 Using Collation in INFORMATION_SCHEMA Searches

String columns in `INFORMATION_SCHEMA` tables have a collation of `utf8_general_ci`, which is case-insensitive. However, for values that correspond to objects that are represented in the file system, such as databases and tables, searches in `INFORMATION_SCHEMA` string columns can be case-sensitive or case-insensitive, depending on the characteristics of the underlying file system and the value of the `lower_case_table_names` system variable. For example, searches may be case-sensitive if the file system is case-sensitive. This section describes this behavior and how to modify it if necessary; see also Bug #34921.

Suppose that a query searches the `SCHEMATA.SCHEMA_NAME` column for the `test` database. On Linux, file systems are case-sensitive, so comparisons of `SCHEMATA.SCHEMA_NAME` with `'test'` match, but comparisons with `'TEST'` do not:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'TEST';
Empty set (0.00 sec)
```

These results occur with the `lower_case_table_names` system variable set to 0. Changing the value of `lower_case_table_names` to 1 or 2 causes the second query to return the same (nonempty) result as the first query.

On Windows or macOS, file systems are not case-sensitive, so comparisons match both `'test'` and `'TEST'`:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'TEST';
+-----+
| SCHEMA_NAME |
+-----+
| TEST        |
+-----+
```

The value of `lower_case_table_names` makes no difference in this context.

The preceding behavior occurs because the `utf8_general_ci` collation is not used for `INFORMATION_SCHEMA` queries when searching for values that correspond to objects represented in the file system. It is a result of file system-scanning optimizations implemented for `INFORMATION_SCHEMA` searches. For information about these optimizations, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

If the result of a string operation on an `INFORMATION_SCHEMA` column differs from expectations, a workaround is to use an explicit `COLLATE` clause to force a suitable collation (see [Section 10.8.1, “Using COLLATE in SQL Statements”](#)). For example, to perform a case-insensitive search, use `COLLATE` with the `INFORMATION_SCHEMA` column name:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'TEST';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+
```

In the preceding queries, it is important to apply the `COLLATE` clause to the `INFORMATION_SCHEMA` column name. Applying `COLLATE` to the comparison value has no effect.

You can also use the `UPPER()` or `LOWER()` function:

```
WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'
```

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named `city`, `CITY`, and `City` can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly. The first of the following comparisons (with `utf8_bin`) is case-sensitive; the others are not:

```
WHERE TABLE_NAME COLLATE utf8_bin = 'City'
WHERE TABLE_NAME COLLATE utf8_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'
```

Searches in `INFORMATION_SCHEMA` string columns for values that refer to `INFORMATION_SCHEMA` itself do use the `utf8_general_ci` collation because `INFORMATION_SCHEMA` is a “virtual” database not represented in the file system. For example, comparisons with `SCHEMATA.SCHEMA_NAME` match `'information_schema'` or `'INFORMATION_SCHEMA'` regardless of platform:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'information_schema';
+-----+
| SCHEMA_NAME |
+-----+
| information_schema |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'INFORMATION_SCHEMA';
+-----+
| SCHEMA_NAME |
+-----+
| information_schema |
+-----+
```

10.9 Unicode Support

The Unicode Standard includes characters from the Basic Multilingual Plane (BMP) and supplementary characters that lie outside the BMP. This section describes support for Unicode in MySQL. For information about the Unicode Standard itself, visit the [Unicode Consortium website](#).

BMP characters have these characteristics:

- Their code point values are between 0 and 65535 (or `U+0000` and `U+FFFF`).
- They can be encoded in a variable-length encoding using 8, 16, or 24 bits (1 to 3 bytes).
- They can be encoded in a fixed-length encoding using 16 bits (2 bytes).
- They are sufficient for almost all characters in major languages.

Supplementary characters lie outside the BMP:

- Their code point values are between `U+10000` and `U+10FFFF`.
- Unicode support for supplementary characters requires character sets that have a range outside BMP characters and therefore take more space than BMP characters (up to 4 bytes per character).

The UTF-8 (Unicode Transformation Format with 8-bit units) method for encoding Unicode data is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.
- Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.
- Korean, Chinese, and Japanese ideographs use 3-byte or 4-byte sequences.

MySQL supports these Unicode character sets:

- `utf8mb4`: A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- `utf8mb3`: A UTF-8 encoding of the Unicode character set using one to three bytes per character.
- `utf8`: An alias for `utf8mb3`.
- `ucs2`: The UCS-2 encoding of the Unicode character set using two bytes per character.
- `utf16`: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like `ucs2` but with an extension for supplementary characters.
- `utf32`: The UTF-32 encoding for the Unicode character set using four bytes per character.

[Table 10.2, “Unicode Character Set General Characteristics”](#), summarizes the general characteristics of Unicode character sets supported by MySQL.

Table 10.2 Unicode Character Set General Characteristics

| Character Set | Supported Characters | Required Storage Per Character |
|--|-----------------------|--------------------------------|
| <code>utf8mb3</code> , <code>utf8</code> | BMP only | 1, 2, or 3 bytes |
| <code>ucs2</code> | BMP only | 2 bytes |
| <code>utf8mb4</code> | BMP and supplementary | 1, 2, 3, or 4 bytes |
| <code>utf16</code> | BMP and supplementary | 2 or 4 bytes |
| <code>utf32</code> | BMP and supplementary | 4 bytes |

Characters outside the BMP compare as REPLACEMENT CHARACTER and convert to '?' when converted to a Unicode character set that supports only BMP characters (`utf8mb3` or `ucs2`).

If you use character sets that support supplementary characters and thus are “wider” than the BMP-only `utf8mb3` and `ucs2` character sets, there are potential incompatibility issues for your applications;

see [Section 10.9.7, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”](#). That section also describes how to convert tables from the (3-byte) `utf8mb3` to the (4-byte) `utf8mb4`, and what constraints may apply in doing so.

A similar set of collations is available for each Unicode character set. For example, each has a Danish collation, the names of which are `utf8mb4_danish_ci`, `utf8mb3_danish_ci`, `utf8_danish_ci`, `ucs2_danish_ci`, `utf16_danish_ci`, and `utf32_danish_ci`. For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see [Section 10.10.1, “Unicode Character Sets”](#).

Although many of the supplementary characters come from East Asian languages, what MySQL 5.5 adds is support for more Japanese and Chinese characters in Unicode character sets, not support for new Japanese and Chinese character sets.

The MySQL implementation of UCS-2, UTF-16, and UTF-32 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-endian byte order or a BOM. In such cases, conversion of values will need to be performed when transferring data between those systems and MySQL.

MySQL uses no BOM for UTF-8 values.

Client applications that communicate with the server using Unicode should set the client character set accordingly (for example, by issuing a `SET NAMES 'utf8mb4'` statement). Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` or `SET CHARACTER SET` produces an error. See [Impermissible Client Character Sets](#).

The following sections provide additional detail on the Unicode character sets in MySQL.

10.9.1 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

The `utf8mb4` character set has these characteristics:

- Supports BMP and supplementary characters.
- Requires a maximum of four bytes per multibyte character.

`utf8mb4` contrasts with the `utf8mb3` character set, which supports only BMP characters and uses a maximum of three bytes per character:

- For a BMP character, `utf8mb4` and `utf8mb3` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf8mb4` requires four bytes to store it, whereas `utf8mb3` cannot store the character at all. When converting `utf8mb3` columns to `utf8mb4`, you need not worry about converting supplementary characters because there will be none.

`utf8mb4` is a superset of `utf8mb3`, so for an operation such as the following concatenation, the result has character set `utf8mb4` and the collation of `utf8mb4_col`:

```
SELECT CONCAT(utf8mb3_col, utf8mb4_col);
```

Similarly, the following comparison in the `WHERE` clause works according to the collation of `utf8mb4_col`:

```
SELECT * FROM utf8mb3_tbl, utf8mb4_tbl
WHERE utf8mb3_tbl.utf8mb3_col = utf8mb4_tbl.utf8mb4_col;
```

For information about data type storage as it relates to multibyte character sets, see [String Type Storage Requirements](#).

10.9.2 The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)

The `utf8mb3` character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Requires a maximum of three bytes per multibyte character.

Applications that use UTF-8 data but require supplementary character support should use `utf8mb4` rather than `utf8mb3` (see [Section 10.9.1, “The utf8mb4 Character Set \(4-Byte UTF-8 Unicode Encoding\)”](#)).

Exactly the same set of characters is available in `utf8mb3` and `ucs2`. That is, they have the same repertoire.

`utf8` is an alias for `utf8mb3`; the character limit is implicit, rather than explicit in the name.

`utf8mb3` can be used in `CHARACTER SET` clauses, and `utf8mb3_collation_substring` in `COLLATE` clauses, where `collation_substring` is `bin`, `czech_ci`, `danish_ci`, `esperanto_ci`, `estonian_ci`, and so forth. For example:

```
CREATE TABLE t (s1 CHAR(1) CHARACTER SET utf8mb3;
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR CHARACTER SET utf8) COLLATE utf8_czech_ci;
```

MySQL immediately converts instances of `utf8mb3` in statements to `utf8`, so in statements such as `SHOW CREATE TABLE` or `SELECT CHARACTER_SET_NAME FROM INFORMATION_SCHEMA.COLUMNS` or `SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLUMNS`, users will see the name `utf8` or `utf8_collation_substring`.

`utf8mb3` is also valid in contexts other than `CHARACTER SET` clauses. For example:

```
mysqld --character-set-server=utf8mb3
```

```
SET NAMES 'utf8mb3'; /* and other SET statements that have similar effect */
SELECT _utf8mb3 'a';
```

There is no `utf8mb3` collation corresponding to the `utf8` collation for collation names that include a version number to indicate the Unicode Collation Algorithm version on which the collation is based (for example, `utf8_unicode_520_ci`).

For information about data type storage as it relates to multibyte character sets, see [String Type Storage Requirements](#).

10.9.3 The utf8 Character Set (Alias for utf8mb3)

`utf8` is an alias for the `utf8mb3` character set. For more information, see [Section 10.9.2, “The utf8mb3 Character Set \(3-Byte UTF-8 Unicode Encoding\)”](#).

10.9.4 The ucs2 Character Set (UCS-2 Unicode Encoding)

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example: `LATIN CAPITAL LETTER A` has the code `0x0041` and it is stored as a 2-byte sequence: `0x00 0x41`. `CYRILLIC SMALL LETTER YERU` (Unicode `0x044B`) is stored as a 2-byte sequence: `0x04 0x4B`. For Unicode characters and their codes, please refer to the [Unicode Consortium website](#).

The `ucs2` character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Uses a fixed-length 16-bit encoding and requires two bytes per character.

10.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)

The `utf16` character set is the `ucs2` character set with an extension that enables encoding of supplementary characters:

- For a BMP character, `utf16` and `ucs2` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf16` has a special sequence for representing the character using 32 bits. This is called the “surrogate” mechanism: For a number greater than `0xffff`, take 10 bits and add them to `0xd800` and put them in the first 16-bit word, take 10 more bits and add them to `0xdc00` and put them in the next 16-bit word. Consequently, all supplementary characters require 32 bits, where the first 16 bits are a number between `0xd800` and `0xdbff`, and the last 16 bits are a number between `0xdc00` and `0xdfff`. Examples are in Section 15.5 [Surrogates Area](#) of the Unicode 4.0 document.

Because `utf16` supports surrogates and `ucs2` does not, there is a validity check that applies only in `utf16`: You cannot insert a top surrogate without a bottom surrogate, or vice versa. For example:

```
INSERT INTO t (ucs2_column) VALUES (0xd800); /* legal */
INSERT INTO t (utf16_column)VALUES (0xd800); /* illegal */
```

There is no validity check for characters that are technically valid but are not true Unicode (that is, characters that Unicode considers to be “unassigned code points” or “private use” characters or even “illegals” like `0xffff`). For example, since `U+F8FF` is the Apple Logo, this is legal:

```
INSERT INTO t (utf16_column)VALUES (0xf8ff); /* legal */
```

Such characters cannot be expected to mean the same thing to everyone.

Because MySQL must allow for the worst case (that one character requires four bytes) the maximum length of a `utf16` column or index is only half of the maximum length for a `ucs2` column or index. For example, the maximum length of a `MEMORY` table index key is 3072 bytes, so these statements create tables with the longest permitted indexes for `ucs2` and `utf16` columns:

```
CREATE TABLE tf (s1 VARCHAR(1536) CHARACTER SET ucs2) ENGINE=MEMORY;
CREATE INDEX i ON tf (s1);
CREATE TABLE tg (s1 VARCHAR(768) CHARACTER SET utf16) ENGINE=MEMORY;
CREATE INDEX i ON tg (s1);
```

10.9.6 The utf32 Character Set (UTF-32 Unicode Encoding)

The `utf32` character set is fixed length (like `ucs2` and unlike `utf16`). `utf32` uses 32 bits for every character, unlike `ucs2` (which uses 16 bits for every character), and unlike `utf16` (which uses 16 bits for some characters and 32 bits for others).

`utf32` takes twice as much space as `ucs2` and more space than `utf16`, but `utf32` has the same advantage as `ucs2` that it is predictable for storage: The required number of bytes for `utf32` equals the number of characters times 4. Also, unlike `utf16`, there are no tricks for encoding in `utf32`, so the stored value equals the code value.

To demonstrate how the latter advantage is useful, here is an example that shows how to determine a `utf8mb4` value given the `utf32` code value:

```
/* Assume code value = 100cc LINEAR B WHEELED CHARIOT */
CREATE TABLE tmp (utf32_col CHAR(1) CHARACTER SET utf32,
                  utf8mb4_col CHAR(1) CHARACTER SET utf8mb4);
INSERT INTO tmp VALUES (0x000100cc,NULL);
UPDATE tmp SET utf8mb4_col = utf32_col;
SELECT HEX(utf32_col),HEX(utf8mb4_col) FROM tmp;
```

MySQL is very forgiving about additions of unassigned Unicode characters or private-use-area characters. There is in fact only one validity check for `utf32`: No code value may be greater than `0x10ffff`. For example, this is illegal:

```
INSERT INTO t (utf32_column) VALUES (0x110000); /* illegal */
```

10.9.7 Converting Between 3-Byte and 4-Byte Unicode Character Sets

This section describes issues that you may face when converting character data between the `utf8mb3` and `utf8mb4` character sets.

Note

This discussion focuses primarily on converting between `utf8mb3` and `utf8mb4`, but similar principles apply to converting between the `ucs2` character set and character sets such as `utf16` or `utf32`.

The `utf8mb3` and `utf8mb4` character sets differ as follows:

- `utf8mb3` supports only characters in the Basic Multilingual Plane (BMP). `utf8mb4` additionally supports supplementary characters that lie outside the BMP.
- `utf8mb3` uses a maximum of three bytes per character. `utf8mb4` uses a maximum of four bytes per character.

Note

This discussion refers to the `utf8mb3` and `utf8mb4` character set names to be explicit about referring to 3-byte and 4-byte UTF-8 character set data. The exception is that in table definitions, `utf8` is used because MySQL converts instances of `utf8mb3` specified in such definitions to `utf8`, which is an alias for `utf8mb3`.

One advantage of converting from `utf8mb3` to `utf8mb4` is that this enables applications to use supplementary characters. One tradeoff is that this may increase data storage space requirements.

In terms of table content, conversion from `utf8mb3` to `utf8mb4` presents no problems:

- For a BMP character, `utf8mb4` and `utf8mb3` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf8mb4` requires four bytes to store it, whereas `utf8mb3` cannot store the character at all. When converting `utf8mb3` columns to `utf8mb4`, you need not worry about converting supplementary characters because there will be none.

In terms of table structure, these are the primary potential incompatibilities:

- For the variable-length character data types (`VARCHAR` and the `TEXT` types), the maximum permitted length in characters is less for `utf8mb4` columns than for `utf8mb3` columns.
- For all character data types (`CHAR`, `VARCHAR`, and the `TEXT` types), the maximum number of characters that can be indexed is less for `utf8mb4` columns than for `utf8mb3` columns.

Consequently, to convert tables from `utf8mb3` to `utf8mb4`, it may be necessary to change some column or index definitions.

Tables can be converted from `utf8mb3` to `utf8mb4` by using `ALTER TABLE`. Suppose that a table has this definition:

```
CREATE TABLE t1 (
  col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci NOT NULL,
  col2 CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL
) CHARACTER SET utf8;
```

The following statement converts `t1` to use `utf8mb4`:

```
ALTER TABLE t1
  DEFAULT CHARACTER SET utf8mb4,
  MODIFY col1 CHAR(10)
    CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci NOT NULL,
  MODIFY col2 CHAR(10)
```

```
CHARACTER SET utf8mb4 COLLATE utf8mb4_bin NOT NULL;
```

The catch when converting from `utf8mb3` to `utf8mb4` is that the maximum length of a column or index key is unchanged in terms of *bytes*. Therefore, it is smaller in terms of *characters* because the maximum length of a character is four bytes instead of three. For the `CHAR`, `VARCHAR`, and `TEXT` data types, watch for these issues when converting your MySQL tables:

- Check all definitions of `utf8mb3` columns and make sure they will not exceed the maximum length for the storage engine.
- Check all indexes on `utf8mb3` columns and make sure they will not exceed the maximum length for the storage engine. Sometimes the maximum can change due to storage engine enhancements.

If the preceding conditions apply, you must either reduce the defined length of columns or indexes, or continue to use `utf8mb3` rather than `utf8mb4`.

Here are some examples where structural changes may be needed:

- A `TINYTEXT` column can hold up to 255 bytes, so it can hold up to 85 3-byte or 63 4-byte characters. Suppose that you have a `TINYTEXT` column that uses `utf8mb3` but must be able to contain more than 63 characters. You cannot convert it to `utf8mb4` unless you also change the data type to a longer type such as `TEXT`.

Similarly, a very long `VARCHAR` column may need to be changed to one of the longer `TEXT` types if you want to convert it from `utf8mb3` to `utf8mb4`.

- `InnoDB` has a maximum index length of 767 bytes, so for `utf8mb3` or `utf8mb4` columns, you can index a maximum of 255 or 191 characters, respectively. If you currently have `utf8mb3` columns with indexes longer than 191 characters, you will need to index a smaller number of characters. In an `InnoDB` table, these column and index definitions are legal:

```
col1 VARCHAR(500) CHARACTER SET utf8, INDEX (col1(255))
```

To use `utf8mb4` instead, the index must be smaller:

```
col1 VARCHAR(500) CHARACTER SET utf8mb4, INDEX (col1(191))
```

The preceding types of changes are most likely to be required only if you have very long columns or indexes. Otherwise, you should be able to convert your tables from `utf8mb3` to `utf8mb4` without problems, using `ALTER TABLE` as described previously.

The following items summarize other potential incompatibilities:

- `SET NAMES 'utf8mb4'` causes use of the 4-byte character set for connection character sets. As long as no 4-byte characters are sent from the server, there should be no problems. Otherwise, applications that expect to receive a maximum of three bytes per character may have problems. Conversely, applications that expect to send 4-byte characters must ensure that the server understands them.
- For replication, if character sets that support supplementary characters are to be used on the master, all slaves must understand them as well.

Also, keep in mind the general principle that if a table has different definitions on the master and slave, this can lead to unexpected results. For example, the differences in maximum index key length make it risky to use `utf8mb3` on the master and `utf8mb4` on the slave.

If you have converted to `utf8mb4`, `utf16`, or `utf32`, and then decide to convert back to `utf8mb3` or `ucs2` (for example, to downgrade to an older version of MySQL), these considerations apply:

- `utf8mb3` and `ucs2` data should present no problems.
- The server must be recent enough to recognize definitions referring to the character set from which you are converting.

- For object definitions that refer to the `utf8mb4` character set, you can dump them with `mysqldump` prior to downgrading, edit the dump file to change instances of `utf8mb4` to `utf8`, and reload the file in the older server, as long as there are no 4-byte characters in the data. The older server will see `utf8` in the dump file object definitions and create new objects that use the (3-byte) `utf8` character set.

10.10 Supported Character Sets and Collations

This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

To list the available character sets and their default collations, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table. For example:

```
mysql> SHOW CHARACTER SET;
```

| Charset | Description | Default collation | Maxlen |
|----------|-----------------------------|---------------------|--------|
| big5 | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8 | DEC West European | dec8_swedish_ci | 1 |
| cp850 | DOS West European | cp850_general_ci | 1 |
| hp8 | HP West European | hp8_english_ci | 1 |
| koi8r | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1 | cp1252 West European | latin1_swedish_ci | 1 |
| latin2 | ISO 8859-2 Central European | latin2_general_ci | 1 |
| swe7 | 7bit Swedish | swe7_swedish_ci | 1 |
| ascii | US ASCII | ascii_general_ci | 1 |
| ujis | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| hebrew | ISO 8859-8 Hebrew | hebrew_general_ci | 1 |
| tis620 | TIS620 Thai | tis620_thai_ci | 1 |
| euckr | EUC-KR Korean | euckr_korean_ci | 2 |
| koi8u | KOI8-U Ukrainian | koi8u_general_ci | 1 |
| gb2312 | GB2312 Simplified Chinese | gb2312_chinese_ci | 2 |
| greek | ISO 8859-7 Greek | greek_general_ci | 1 |
| cp1250 | Windows Central European | cp1250_general_ci | 1 |
| gbk | GBK Simplified Chinese | gbk_chinese_ci | 2 |
| latin5 | ISO 8859-9 Turkish | latin5_turkish_ci | 1 |
| armscii8 | ARMScii8 Armenian | armscii8_general_ci | 1 |
| utf8 | UTF-8 Unicode | utf8_general_ci | 3 |
| ucs2 | UCS-2 Unicode | ucs2_general_ci | 2 |
| cp866 | DOS Russian | cp866_general_ci | 1 |
| keybcs2 | DOS Kamenicky Czech-Slovak | keybcs2_general_ci | 1 |
| macce | Mac Central European | macce_general_ci | 1 |
| macroman | Mac West European | macroman_general_ci | 1 |
| cp852 | DOS Central European | cp852_general_ci | 1 |
| latin7 | ISO 8859-13 Baltic | latin7_general_ci | 1 |
| utf8mb4 | UTF-8 Unicode | utf8mb4_general_ci | 4 |
| cp1251 | Windows Cyrillic | cp1251_general_ci | 1 |
| utf16 | UTF-16 Unicode | utf16_general_ci | 4 |
| cp1256 | Windows Arabic | cp1256_general_ci | 1 |
| cp1257 | Windows Baltic | cp1257_general_ci | 1 |
| utf32 | UTF-32 Unicode | utf32_general_ci | 4 |
| binary | Binary pseudo charset | binary | 1 |
| geostd8 | GEOSTD8 Georgian | geostd8_general_ci | 1 |
| cp932 | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

10.10.1 Unicode Character Sets

This section describes the collations available for Unicode character sets and their differentiating properties. For general information about Unicode, see [Section 10.9, “Unicode Support”](#).

MySQL supports multiple Unicode character sets:

- `utf8mb4`: A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- `utf8mb3`: A UTF-8 encoding of the Unicode character set using one to three bytes per character.
- `utf8`: An alias for `utf8mb3`.
- `ucs2`: The UCS-2 encoding of the Unicode character set using two bytes per character.
- `utf16`: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like `ucs2` but with an extension for supplementary characters.
- `utf32`: The UTF-32 encoding for the Unicode character set using four bytes per character.

`utf8mb4`, `utf16`, and `utf32` support Basic Multilingual Plane (BMP) characters and supplementary characters that lie outside the BMP. `utf8` and `ucs2` support only BMP characters.

Most Unicode character sets have a general collation (indicated by `_general` in the name or by the absence of a language specifier), a binary collation (indicated by `_bin` in the name), and several language-specific collations (indicated by language specifiers). For example, for `utf8mb4`, `utf8mb4_general_ci` and `utf8mb4_bin` are its general and binary collations, and `utf8mb4_danish_ci` is one of its language-specific collations.

- [Unicode Collation Algorithm \(UCA\) Versions](#)
- [Language-Specific Collations](#)
- [_general_ci Versus _unicode_ci Collations](#)
- [Character Collating Weights](#)
- [Miscellaneous Information](#)

Unicode Collation Algorithm (UCA) Versions

MySQL implements the `xxx_unicode_ci` collations according to the Unicode Collation Algorithm (UCA) described at <http://www.unicode.org/reports/tr10/>. The collation uses the version-4.0.0 UCA weight keys: <http://www.unicode.org/Public/UC4.0.0/allkeys-4.0.0.txt>. The `xxx_unicode_ci` collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported, and combining marks are not fully supported. This affects primarily Vietnamese, Yoruba, and some smaller languages such as Navajo. A combined character is considered different from the same character written with a single unicode character in string comparisons, and the two characters are considered to have a different length (for example, as returned by the `CHAR_LENGTH()` function or in result set metadata).

Language-Specific Collations

MySQL implements language-specific Unicode collations if the ordering based only on the Unicode Collation Algorithm (UCA) does not work well for a language. Language-specific collations are UCA-based, with additional language tailoring rules. Examples of such rules appear later in this section. For questions about particular language orderings, [unicode.org](http://www.unicode.org) provides Common Locale Data Repository (CLDR) collation charts at <http://www.unicode.org/cldr/charts/30/collation/index.html>.

A language name shown in the following table indicates a language-specific collation. Unicode character sets may include collations for one or more of these languages.

Table 10.3 Unicode Collation Language Specifiers

| Language | Language Specifier |
|-----------------|--------------------|
| Classical Latin | <code>roman</code> |

| Language | Language Specifier |
|---------------------|-------------------------|
| Czech | <code>czech</code> |
| Danish | <code>danish</code> |
| Esperanto | <code>esperanto</code> |
| Estonian | <code>estonian</code> |
| Hungarian | <code>hungarian</code> |
| Icelandic | <code>icelandic</code> |
| Latvian | <code>latvian</code> |
| Lithuanian | <code>lithuanian</code> |
| Persian | <code>persian</code> |
| Polish | <code>polish</code> |
| Romanian | <code>romanian</code> |
| Sinhala | <code>sinhala</code> |
| Slovak | <code>slovak</code> |
| Slovenian | <code>slovenian</code> |
| Modern Spanish | <code>spanish</code> |
| Traditional Spanish | <code>spanish2</code> |
| Swedish | <code>swedish</code> |
| Turkish | <code>turkish</code> |

Danish collations may also be used for Norwegian.

For Classical Latin collations, `I` and `J` compare as equal, and `U` and `V` compare as equal.

Spanish collations are available for modern and traditional Spanish. For both, `ñ` (n-tilde) is a separate letter between `n` and `o`. In addition, for traditional Spanish, `ch` is a separate letter between `c` and `d`, and `ll` is a separate letter between `l` and `m`.

Traditional Spanish collations may also be used for Asturian and Galician.

Swedish collations include Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

```
Ü = Y < Ö
```

`_general_ci` Versus `_unicode_ci` Collations

For any Unicode character set, operations performed using the `xxx_general_ci` collation are faster than those for the `xxx_unicode_ci` collation. For example, comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. The reason is that `utf8_unicode_ci` supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, `ß` is equal to `ss` in German and some other languages. `utf8_unicode_ci` also supports contractions and ignorable characters. `utf8_general_ci` is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both `utf8_general_ci` and `utf8_unicode_ci` (for the effect of this in comparisons or searches, see [Section 10.8.6, “Examples of the Effect of Collation”](#)):

```
Ä = A
Ö = O
Ü = U
```

A difference between the collations is that this is true for `utf8_general_ci`:

```
ß = s
```

Whereas this is true for `utf8_unicode_ci`, which supports the German DIN-1 ordering (also known as dictionary order):

```
ß = ss
```

MySQL implements `utf8` language-specific collations if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German dictionary order and French, so there is no need to create special `utf8` collations.

`utf8_general_ci` also is satisfactory for both German and French, except that `ß` is equal to `s`, and not to `ss`. If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. Otherwise, use `utf8_unicode_ci` because it is more accurate.

Character Collating Weights

For all Unicode collations except the `_bin` (binary) collations, MySQL performs a table lookup to find a character's collating weight. If a character is not in the table (for example, because it is a “new” character), collating weight determination becomes more complex:

- For BMP characters in general collations (`xxx_general_ci`), the weight is the code point.
- For BMP characters in UCA collations (for example, `xxx_unicode_ci` and language-specific collations), the following algorithm applies:

```
if (code >= 0x3400 && code <= 0x4DB5)
    base= 0xFB80; /* CJK Ideograph Extension */
else if (code >= 0x4E00 && code <= 0x9FA5)
    base= 0xFB40; /* CJK Ideograph */
else
    base= 0xFBC0; /* All other characters */
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;
```

The result is a sequence of two collating elements, `aaaa` followed by `bbbb`.

Thus, `U+04cf CYRILLIC SMALL LETTER PALOCHKA` currently is, with all UCA collations, greater than `U+04c0 CYRILLIC LETTER PALOCHKA`. Eventually, after further collation tuning, all palochkas will sort together.

- For supplementary characters in general collations, the weight is the weight for `0xffff REPLACEMENT CHARACTER`. For supplementary characters in UCA 4.0.0 collations, their collating weight is `0xffff`. That is, to MySQL, all supplementary characters are equal to each other, and greater than almost all BMP characters.

An example with Deseret characters and `COUNT(DISTINCT)`:

```
CREATE TABLE t (s1 VARCHAR(5) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0xffff); /* REPLACEMENT CHARACTER */
INSERT INTO t VALUES (0x010412); /* DESERET CAPITAL LETTER BEE */
INSERT INTO t VALUES (0x010413); /* DESERET CAPITAL LETTER TEE */
SELECT COUNT(DISTINCT s1) FROM t;
```

The result is 2 because in the MySQL `xxx_unicode_ci` collations, the replacement character has a weight of `0x0dc6`, whereas Deseret Bee and Deseret Tee both have a weight of `0xffff`. (Were the `utf32_general_ci` collation used instead, the result is 1 because all three characters have a weight of `0xffff` in that collation.)

The rule that all supplementary characters are equal to each other is nonoptimal but is not expected to cause trouble. These characters are very rare, so it is very rare that a multi-character string consists entirely of supplementary characters. In Japan, since the supplementary characters are obscure Kanji

ideographs, the typical user does not care what order they are in, anyway. If you really want rows sorted by the MySQL rule and secondarily by code point value, it is easy:

```
ORDER BY s1 COLLATE utf32_unicode_ci, s1 COLLATE utf32_bin
```

There is a difference between “ordering by the character's code value” and “ordering by the character's binary representation,” a difference that appears only with `utf16_bin`, because of surrogates.

Suppose that `utf16_bin` (the binary collation for `utf16`) was a binary comparison “byte by byte” rather than “character by character.” If that were so, the order of characters in `utf16_bin` would differ from the order in `utf8_bin`. For example, the following chart shows two rare characters. The first character is in the range `E000-FFFF`, so it is greater than a surrogate but less than a supplementary. The second character is a supplementary.

| Code point | Character | utf8 | utf16 |
|------------|-----------------------------|-------------|-------------|
| 0FF9D | HALFWIDTH KATAKANA LETTER N | EF BE 9D | FF 9D |
| 10384 | UGARITIC LETTER DELTA | F0 90 8E 84 | D8 00 DF 84 |

The two characters in the chart are in order by code point value because `0xff9d < 0x10384`. And they are in order by `utf8` value because `0xef < 0xf0`. But they are not in order by `utf16` value, if we use byte-by-byte comparison, because `0xff > 0xd8`.

So MySQL's `utf16_bin` collation is not “byte by byte.” It is “by code point.” When MySQL sees a supplementary-character encoding in `utf16`, it converts to the character's code-point value, and then compares. Therefore, `utf8_bin` and `utf16_bin` are the same ordering. This is consistent with the SQL:2008 standard requirement for a UCS_BASIC collation: “UCS_BASIC is a collation in which the ordering is determined entirely by the Unicode scalar values of the characters in the strings being sorted. It is applicable to the UCS character repertoire. Since every character repertoire is a subset of the UCS repertoire, the UCS_BASIC collation is potentially applicable to every character set. NOTE 11: The Unicode scalar value of a character is its code point treated as an unsigned integer.”

If the character set is `ucs2`, comparison is byte-by-byte, but `ucs2` strings should not contain surrogates, anyway.

Miscellaneous Information

The `xxx_general_mysql500_ci` collations were added in MySQL 5.5.21. They preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

10.10.2 West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:
 - `ascii_bin`
 - `ascii_general_ci` (default)
- `cp850` (DOS West European) collations:
 - `cp850_bin`
 - `cp850_general_ci` (default)
- `dec8` (DEC Western European) collations:
 - `dec8_bin`

- `dec8_swedish_ci` (default)
- `hp8` (HP Western European) collations:
 - `hp8_bin`
 - `hp8_english_ci` (default)
- `latin1` (cp1252 West European) collations:
 - `latin1_bin`
 - `latin1_danish_ci`
 - `latin1_general_ci`
 - `latin1_general_cs`
 - `latin1_german1_ci`
 - `latin1_german2_ci`
 - `latin1_spanish_ci`
 - `latin1_swedish_ci` (default)

`latin1` is the default character set. MySQL's `latin1` is the same as the Windows `cp1252` character set. This means it is the same as the official ISO 8859-1 or IANA (Internet Assigned Numbers Authority) `latin1`, except that IANA `latin1` treats the code points between `0x80` and `0x9f` as “undefined,” whereas `cp1252`, and therefore MySQL's `latin1`, assign characters for those positions. For example, `0x80` is the Euro sign. For the “undefined” entries in `cp1252`, MySQL translates `0x81` to Unicode `0x0081`, `0x8d` to `0x008d`, `0x8f` to `0x008f`, `0x90` to `0x0090`, and `0x9d` to `0x009d`.

The `latin1_swedish_ci` collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for *Deutsches Institut für Normung* (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see [Section 10.8.6, “Examples of the Effect of Collation”](#).

- `latin1_german1_ci` (dictionary) rules:

```

Ä = A
Ö = O
Ü = U
ß = s

```

- `latin1_german2_ci` (phone-book) rules:

```

Ä = AE
Ö = OE
Ü = UE
ß = ss

```

In the `latin1_spanish_ci` collation, ñ (n-tilde) is a separate letter between `n` and `o`.

- `macroman` (Mac West European) collations:
 - `macroman_bin`

- `macroman_general_ci` (default)
- `swe7` (7bit Swedish) collations:
 - `swe7_bin`
 - `swe7_swedish_ci` (default)

10.10.3 Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- `cp1250` (Windows Central European) collations:
 - `cp1250_bin`
 - `cp1250_croatian_ci`
 - `cp1250_czech_cs`
 - `cp1250_general_ci` (default)
 - `cp1250_polish_ci`
- `cp852` (DOS Central European) collations:
 - `cp852_bin`
 - `cp852_general_ci` (default)
- `keybcs2` (DOS Kamenicky Czech-Slovak) collations:
 - `keybcs2_bin`
 - `keybcs2_general_ci` (default)
- `latin2` (ISO 8859-2 Central European) collations:
 - `latin2_bin`
 - `latin2_croatian_ci`
 - `latin2_czech_cs`
 - `latin2_general_ci` (default)
 - `latin2_hungarian_ci`
- `macce` (Mac Central European) collations:
 - `macce_bin`
 - `macce_general_ci` (default)

10.10.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- `armscii8` (ARMSCII-8 Armenian) collations:

- `armscii8_bin`
- `armscii8_general_ci` (default)
- `cp1256` (Windows Arabic) collations:
 - `cp1256_bin`
 - `cp1256_general_ci` (default)
- `geostd8` (GEOSTD8 Georgian) collations:
 - `geostd8_bin`
 - `geostd8_general_ci` (default)
- `greek` (ISO 8859-7 Greek) collations:
 - `greek_bin`
 - `greek_general_ci` (default)
- `hebrew` (ISO 8859-8 Hebrew) collations:
 - `hebrew_bin`
 - `hebrew_general_ci` (default)
- `latin5` (ISO 8859-9 Turkish) collations:
 - `latin5_bin`
 - `latin5_turkish_ci` (default)

10.10.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- `cp1257` (Windows Baltic) collations:
 - `cp1257_bin`
 - `cp1257_general_ci` (default)
 - `cp1257_lithuanian_ci`
- `latin7` (ISO 8859-13 Baltic) collations:
 - `latin7_bin`
 - `latin7_estonian_cs`
 - `latin7_general_ci` (default)
 - `latin7_general_cs`

10.10.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

- `cp1251` (Windows Cyrillic) collations:

- `cp1251_bin`
- `cp1251_bulgarian_ci`
- `cp1251_general_ci` (default)
- `cp1251_general_cs`
- `cp1251_ukrainian_ci`
- `cp866` (DOS Russian) collations:
 - `cp866_bin`
 - `cp866_general_ci` (default)
- `koi8r` (KOI8-R Relcom Russian) collations:
 - `koi8r_bin`
 - `koi8r_general_ci` (default)
- `koi8u` (KOI8-U Ukrainian) collations:
 - `koi8u_bin`
 - `koi8u_general_ci` (default)

10.10.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See [Section 10.10.7.1, “The cp932 Character Set”](#), for additional information about the `cp932` and `sjis` character sets.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see [Section A.11, “MySQL 5.5 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”](#).

- `big5` (Big5 Traditional Chinese) collations:
 - `big5_bin`
 - `big5_chinese_ci` (default)
- `cp932` (SJIS for Windows Japanese) collations:
 - `cp932_bin`
 - `cp932_japanese_ci` (default)
- `ujis` (UJIS for Windows Japanese) collations:
 - `ujis_bin`
 - `ujis_japanese_ci` (default)
- `euckr` (EUC-KR Korean) collations:
 - `euckr_bin`
 - `euckr_korean_ci` (default)
- `gb2312` (GB2312 Simplified Chinese) collations:

- `gb2312_bin`
- `gb2312_chinese_ci` (default)
- `gbk` (GBK Simplified Chinese) collations:
 - `gbk_bin`
 - `gbk_chinese_ci` (default)
- `sjis` (Shift-JIS Japanese) collations:
 - `sjis_bin`
 - `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
 - `tis620_bin`
 - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
 - `ujis_bin`
 - `ujis_japanese_ci` (default)

The `big5_chinese_ci` collation sorts on number of strokes.

10.10.7.1 The `cp932` Character Set

Why is `cp932` needed?

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See <http://www.iana.org/assignments/character-sets>.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is `Microsoft Windows Codepage : 932` or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted using Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

How does cp932 differ from sjis?

The cp932 character set differs from sjis in the following ways:

- cp932 supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.
- Some cp932 characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to cp932, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See <http://support.microsoft.com/kb/170559/EN-US/>.)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
- If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

The table shown at <https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx> provides information about the Unicode values of cp932 characters. For cp932 table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (ucs2) encoding. For table entries with an underlined two-digit value appears, there is a range of cp932 character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the cp932 characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters (lead byte 0x87):

<https://msdn.microsoft.com/en-us/goglobal/gg674964>

- NEC selected—IBM extended characters (lead byte 0xED and 0xEE):

<https://msdn.microsoft.com/en-us/goglobal/gg671837>
<https://msdn.microsoft.com/en-us/goglobal/gg671838>

- IBM selected characters (lead byte 0xFA, 0xFB, 0xFC):

<https://msdn.microsoft.com/en-us/goglobal/gg671839>
<https://msdn.microsoft.com/en-us/goglobal/gg671840>
<https://msdn.microsoft.com/en-us/goglobal/gg671841>

- cp932 supports conversion of user-defined characters in combination with eucjpms, and solves the problems with sjis/ujis conversion. For details, please refer to <http://www.sjfaq.org/afaq/encodings.html>.

For some characters, conversion to and from ucs2 is different for sjis and cp932. The following tables illustrate these differences.

Conversion to ucs2:

| sjis/cp932 Value | sjis -> ucs2 Conversion | cp932 -> ucs2 Conversion |
|------------------|-------------------------|--------------------------|
| 5C | 005C | 005C |
| 7E | 007E | 007E |
| 815C | 2015 | 2015 |

| sjis/cp932 Value | sjis -> ucs2 Conversion | cp932 -> ucs2 Conversion |
|-------------------------|-----------------------------------|------------------------------------|
| 815F | 005C | FF3C |
| 8160 | 301C | FF5E |
| 8161 | 2016 | 2225 |
| 817C | 2212 | FF0D |
| 8191 | 00A2 | FFE0 |
| 8192 | 00A3 | FFE1 |
| 81CA | 00AC | FFE2 |

Conversion from `ucs2`:

| ucs2 value | ucs2 -> sjis Conversion | ucs2 -> cp932 Conversion |
|-------------------|-----------------------------------|------------------------------------|
| 005C | 815F | 5C |
| 007E | 7E | 7E |
| 00A2 | 8191 | 3F |
| 00A3 | 8192 | 3F |
| 00AC | 81CA | 3F |
| 2015 | 815C | 815C |
| 2016 | 8161 | 3F |
| 2212 | 817C | 3F |
| 2225 | 3F | 8161 |
| 301C | 8160 | 3F |
| FF0D | 3F | 817C |
| FF3C | 3F | 815F |
| FF5E | 3F | 8160 |
| FFE0 | 3F | 8191 |
| FFE1 | 3F | 8192 |
| FFE2 | 3F | 81CA |

Users of any Japanese character sets should be aware that using `--character-set-client-handshake` (or `--skip-character-set-client-handshake`) has an important effect. See [Section 5.1.6, “Server Command Options”](#).

10.10.8 The Binary Character Set

The `binary` character set is the character set for binary strings, which are sequences of bytes. The `binary` character set has one collation, also named `binary`. Comparison and sorting are based on numeric byte values, rather than on numeric character code values (which for multibyte characters differ from numeric byte values). For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 10.8.5, “The binary Collation Compared to `_bin` Collations”](#).

For the `binary` character set, the concepts of lettercase and accent equivalence do not apply:

- For single-byte characters stored as binary strings, character and byte boundaries are the same, so lettercase and accent differences are significant in comparisons. That is, the `binary` collation is case-sensitive and accent-sensitive.

```
mysql> SET NAMES 'binary';
mysql> SELECT CHARSET('abc'), COLLATION('abc');
+-----+-----+
```

```

| CHARSET('abc') | COLLATION('abc') |
+-----+-----+
| binary         | binary         |
+-----+-----+
mysql> SELECT 'abc' = 'ABC', 'a' = 'ä';
+-----+-----+
| 'abc' = 'ABC' | 'a' = 'ä'     |
+-----+-----+
|              0 |              0 |
+-----+-----+

```

- For multibyte characters stored as binary strings, character and byte boundaries differ. Character boundaries are lost, so comparisons that depend on them are not meaningful.

To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```

mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-----+-----+
| New York   | new york                           |
+-----+-----+

```

To convert a string expression to a binary string, these constructs are equivalent:

```

BINARY expr
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)

```

If a value is a character string literal, the `_binary` introducer may be used to designate it as a binary string. For example:

```
_binary 'a'
```

The `_binary` introducer is permitted for hexadecimal literals and bit-value literals as well, but unnecessary; such literals are binary strings by default.

For more information about introducers, see [Section 10.3.8, "Character Set Introducers"](#).

10.11 Restrictions on Character Sets

- Identifiers are stored in `mysql` database tables (`user`, `db`, and so forth) using `utf8`, but identifiers can contain only characters in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted in identifiers.
- The `ucs2`, `utf16`, and `utf32` character sets have the following restrictions:
 - None of them can be used as the client character set. See [Impermissible Client Character Sets](#).
 - It is currently not possible to use `LOAD DATA` to load data files that use these character sets.
 - `FULLTEXT` indexes cannot be created on a column that uses any of these character sets. However, you can perform `IN BOOLEAN MODE` searches on the column without an index.
 - The use of `ENCRYPT()` with these character sets is not recommended because the underlying system call expects a string terminated by a zero byte.
- The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

10.12 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can be displayed instead in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish. This applies to messages the server writes to the error log and sends to clients.

To select the language in which the server writes error messages, follow the instructions in this section. For information about changing the character set for error messages (rather than the language), see [Section 10.6, “Error Message Character Set”](#). For general information about configuring error logging, see [Section 5.4.2, “The Error Log”](#).

The server searches for the error message file using these rules:

- It looks for the file in a directory constructed from two system variable values, `lc_messages_dir` and `lc_messages`, with the latter converted to a language name. Suppose that you start the server using this command:

```
mysqld --lc_messages_dir=/usr/share/mysql --lc_messages=fr_FR
```

In this case, `mysqld` maps the locale `fr_FR` to the language `french` and looks for the error file in the `/usr/share/mysql/french` directory.

By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

- If the message file cannot be found in the directory constructed as just described, the server ignores the `lc_messages` value and uses only the `lc_messages_dir` value as the location in which to look.

The `lc_messages_dir` system variable can be set only at server startup and has only a global read-only value at runtime. `lc_messages` can be set at server startup and has global and session values that can be modified at runtime. Thus, the error message language can be changed while the server is running, and each client can have its own error message language by setting its session `lc_messages` value to the desired locale name. For example, if the server is using the `fr_FR` locale for error messages, a client can execute this statement to receive error messages in English:

```
SET lc_messages = 'en_US';
```

10.13 Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

- If the character set does not need special string collating routines for sorting and does not need multibyte character support, it is simple.
- If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

To use the following instructions, you must have a MySQL source distribution. In the instructions, `MYSET` represents the name of the character set that you want to add.

1. Add a `<charset>` element for `MYSET` to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the `latin1` `<charset>` element follows:

```
<charset name="latin1">
  <family>Western</family>
  <description>cpl252 West European</description>
  ...
  <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
    <flag>primary</flag>
```

```

    <flag>compiled</flag>
  </collation>
  <collation name="latin1_danish_ci" id="15" order="Danish"/>
  ...
  <collation name="latin1_bin" id="47" order="Binary">
    <flag>binary</flag>
    <flag>compiled</flag>
  </collation>
  ...
</charset>

```

The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using a suffix of `general_ci` (general, case-insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a `primary` flag. The binary collation should have a `binary` flag.

You must assign a unique ID number to each collation. The range of IDs from 1024 to 2047 is reserved for user-defined collations. To find the maximum of the currently used collation IDs, use this query:

```
SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multibyte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. You can use a copy of `latin1.xml` as the basis for this file. The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).
- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.
- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See [Section 10.13.1, "Character Definition Arrays"](#).
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See [Section 10.13.1, "Character Definition Arrays"](#).
 - For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
 - If the character set requires string collating functions, see [Section 10.13.2, "String Collating Support for Complex Character Sets"](#).
 - If the character set requires multibyte character support, see [Section 10.13.3, "Multi-Byte Character Support for Complex Character Sets"](#).
3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.

- a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```
#ifndef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```
#ifndef HAVE_CHARSET_MYSET
    add_compiled_collation(&my_charset_MYSET_general_ci);
    add_compiled_collation(&my_charset_MYSET_bin);
#endif
```

- b. If the character set uses `ctype-MYSET.c`, edit `strings/CMakeLists.txt` and add `ctype-MYSET.c` to the definition of the `STRINGS_SOURCES` variable.
- c. Edit `cmake/character_sets.cmake`:
- i. Add `MYSET` to the value of `CHARSETS_AVAILABLE` in alphabetic order.
 - ii. Add `MYSET` to the value of `CHARSETS_COMPLEX` in alphabetic order. This is needed even for simple character sets, or CMake will not recognize `-DDEFAULT_CHARSET=MYSET`.
4. Reconfigure, recompile, and test.

10.13.1 Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSYS`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.
- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparison and sorting, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-*.c` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling EOF.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

```
#define _MY_U 01 /* Upper case */
#define _MY_L 02 /* Lower case */
#define _MY_NMR 04 /* Numeral (digit) */
#define _MY_SPC 010 /* Spacing character */
#define _MY_PNT 020 /* Punctuation */
#define _MY_CTR 040 /* Control character */
#define _MY_B 0100 /* Blank */
#define _MY_X 0200 /* hexadecimal digit */
```

The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, 'A' is an uppercase character (`_MY_U`) as well as a hexadecimal digit (`_MY_X`), so its `ctype` value should be defined like this:

```
ctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.

The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in [Section 10.13.2, “String Collating Support for Complex Character Sets”](#).

10.13.2 String Collating Support for Complex Character Sets

For a simple character set named `MYSET`, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

10.13.3 Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named `MYSET` that includes multibyte characters, you must use multibyte character functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets. Take a look at the `MY_CHARSET_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

10.14 Adding a Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

MySQL supports several collation implementations, as discussed in [Section 10.14.1, “Collation Implementation Types”](#). Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary (`xxx_bin`) collations.

The following sections describe how to add collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Summary of the procedure for adding a new collation:

1. Choose a collation ID.
2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the collation is present.

The instructions here cover only collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in [Section 10.13, “Adding a Character Set”](#). However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add data structures, functions, and configuration information for the new collation.

Note

If you modify an existing collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes to avoid problems such as incorrect query results. See [Section 2.11.7, “Rebuilding or Repairing Tables or Indexes”](#).

- The Unicode Collation Algorithm (UCA) specification: <http://www.unicode.org/reports/tr10/>
- The Locale Data Markup Language (LDML) specification: <http://www.unicode.org/reports/tr35/>

10.14.1 Collation Implementation Types

MySQL implements several types of collations:

Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. `latin1_swedish_ci` is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a' = 'A';
+-----+
| 'a' = 'A' |
+-----+
|          1 |
+-----+
1 row in set (0.00 sec)
```

For implementation instructions, see [Section 10.14.3, “Adding a Simple Collation to an 8-Bit Character Set”](#).

Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in [Section 10.13, “Adding a Character Set”](#).

Collations for non-Unicode multibyte character sets

For this type of collation, 8-bit (single-byte) and multibyte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters 'a' and 'A' both have a weight of 0x41.) For multibyte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. `sjis_japanese_ci` is an example of this kind of collation. The multibyte character 'ㇿ' has a character code of 0x82C0, and the weight is also 0x82C0.
- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. `gbk_chinese_ci` is an example of this kind of collation. The multibyte character '臙' has a character code of 0x81B0 but a weight of 0xC286.

For implementation instructions, see [Section 10.13, “Adding a Character Set”](#).

Collations for Unicode multibyte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case-insensitive and accent-insensitive. `utf8_general_ci` is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of 0x0041 and compare as equal.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a' = 'A', 'a' = 'À', 'a' = 'á';
+-----+-----+-----+
| 'a' = 'A' | 'a' = 'À' | 'a' = 'á' |
+-----+-----+-----+
|          1 |          1 |          1 |
+-----+-----+-----+
1 row in set (0.06 sec)
```

UCA-based collations in MySQL have these properties:

- If a character has weights, each weight uses 2 bytes (16 bits).
- A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.
- A character may have one weight. Example: 'a' has a weight of 0x0E33.
- A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ ligature, or SHARP S) has a weight of 0x0FEA0FEA.
- Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of 0x0EE2.

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see [Section 10.13, “Adding a Character Set”](#). For a UCA collation, see [Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”](#).

Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

10.14.2 Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. The range of IDs from 1024 to 2047 is reserved for user-defined collations. Before MySQL 5.5, an ID must be chosen from the range 1 to 254. As of MySQL 5.5, the 254 limit is removed for [MyISAM](#) tables with the introduction of support for two-byte collation IDs. Two-byte collation ID support for [InnoDB](#) tables is not added until MySQL 5.6.

The collation ID that you choose will appear in these contexts:

- The `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table.
- The `Id` column of `SHOW COLLATION` output.
- The `charsetnr` member of the `MYSQL_FIELD` C API data structure.
- The `number` member of the `MY_CHARSET_INFO` data structure returned by the `mysql_get_character_set_info()` C API function.

To determine the largest currently used ID, issue the following statement:

```
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
+-----+
| MAX(ID) |
+-----+
|      210 |
+-----+
```

To display a list of all currently used IDs, issue this statement:

```
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
+-----+
| ID |
+-----+
|  1 |
|  2 |
| ... |
| 52 |
| 53 |
| 57 |
| 58 |
| ... |
| 98 |
| 99 |
|128 |
|129 |
| ... |
|210 |
+-----+
```

Warning

Before upgrading, you should save the configuration files that you change. If you upgrade in place, the process will replace the your modified files.

10.14.3 Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the `<collation>` elements associated with a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. The example adds a collation named `latin1_test_ci` to the `latin1` character set.

1. Choose a collation ID, as shown in [Section 10.14.2, “Choosing a Collation ID”](#). The following steps use an ID of 1024.
2. Modify the `Index.xml` and `latin1.xml` configuration files. These files are located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. For example:

```
<charset name="latin1">
...
  <collation name="latin1_test_ci" id="1024"/>
...
</charset>
```

4. In the `latin1.xml` configuration file, add a `<collation>` element that names the collation and that contains a `<map>` element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the `<map>` element must be a number in hexadecimal format.

```
<collation name="latin1_test_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5C D7 5C 55 55 55 59 59 DE DF
41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5C F7 5C 55 55 55 59 59 DE FF
</map>
</collation>
```

5. Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION WHERE Collation = 'latin1_test_ci';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id   | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_test_ci | latin1 | 1024 |         |          | 1       |
+-----+-----+-----+-----+-----+-----+
```

10.14.4 Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the `<collation>` element within a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at <http://www.unicode.org/reports/tr35/>. With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the base collations of the Unicode character sets for which UCA collations can be defined.

Table 10.4 MySQL Character Sets Available for User-Defined UCA Collations

| Character Set | Base Collation |
|---------------|------------------|
| utf8 | utf8_unicode_ci |
| ucs2 | ucs2_unicode_ci |
| utf16 | utf16_unicode_ci |
| utf32 | utf32_unicode_ci |

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

10.14.4.1 Defining a UCA Collation Using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation's sort characteristics, see [Section 10.14.4.2, "LDML Syntax Supported in MySQL"](#).

The example adds a collation named `utf8_phone_ci` to the `utf8` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

```
+7-12345-67
+7-12-345-67
+7 12 345 67
+7 (12) 345 67
+71234567
```

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in [Section 10.14.2, "Choosing a Collation ID"](#). The following steps use an ID of 1029.
2. To modify the `Index.xml` configuration file. This file is located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. In addition, you'll need to provide the collation ordering rules. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. Within the `<collation>` element, provide a `<rules>` element containing the ordering rules:

```
<charset name="utf8">
...
  <collation name="utf8_phone_ci" id="1029">
    <rules>
      <reset>\u0000</reset>
      <i>\u0020</i> <!-- space -->
      <i>\u0028</i> <!-- left parenthesis -->
      <i>\u0029</i> <!-- right parenthesis -->
      <i>\u002B</i> <!-- plus -->
      <i>\u002D</i> <!-- hyphen -->
    </rules>
```

```
</collation>
...
</charset>
```

4. If you want a similar collation for other Unicode character sets, add other `<collation>` elements. For example, to define `ucs2_phone_ci`, add a `<collation>` element to the `<charset name="ucs2">` element. Remember that each collation must have its own unique ID.
5. Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION WHERE Collation = 'utf8_phone_ci';
+-----+-----+-----+-----+-----+-----+
| Collation      | Charset | Id   | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| utf8_phone_ci | utf8    | 1029 |         |          | 8       |
+-----+-----+-----+-----+-----+-----+
```

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```
mysql> CREATE TABLE phonebook (
    name VARCHAR(64),
    phone VARCHAR(64) CHARACTER SET utf8 COLLATE utf8_phone_ci
);
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
Query OK, 1 row affected (0.00 sec)
```

Run some queries to see whether the ignored punctuation characters are in fact ignored for comparison and sorting:

```
mysql> SELECT * FROM phonebook ORDER BY phone;
+-----+-----+
| name  | phone                |
+-----+-----+
| Sanja | +380 (912) 8008005   |
| Bar   | +7-912-800-80-01    |
| Svoj  | +7 912 800 80 02    |
| Ramil | (7912) 800 80 03    |
| Hf    | +7 (912) 800 80 04  |
+-----+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+-----+-----+
| name  | phone                |
+-----+-----+
| Bar   | +7-912-800-80-01    |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+-----+-----+
| name  | phone                |
+-----+-----+
| Bar   | +7-912-800-80-01    |
+-----+-----+
```

```

+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 0 8 0 0 1';
+-----+-----+
| name | phone          |
+-----+-----+
| Bar  | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

```

10.14.4.2 LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at <http://www.unicode.org/reports/tr35/>, which should be consulted for further information. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

Character Representation

Characters named in LDML rules can be written in `\unnnn` format, where `nnnn` is the hexadecimal Unicode code point value. Within hexadecimal values, the digits `A` through `F` are not case-sensitive; `\u00E1` and `\u00e1` are equivalent. Basic Latin letters `A-Z` and `a-z` can also be written literally (this is a MySQL limitation; the LDML specification permits literal non-Latin1 characters in the rules). Only characters in the Basic Multilingual Plane can be specified. This notation does not apply to characters outside the BMP range of `0000` to `FFFF`.

The `Index.xml` file itself should be written using ASCII encoding.

Syntax Rules

LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

- A `<reset>` rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter `'A'`:

```

<reset>A</reset>

<reset>\u0041</reset>

```

- The `<p>`, `<s>`, and `<t>` shift rules define primary, secondary, and tertiary differences of a character from another character:
 - Use primary differences to distinguish separate letters.
 - Use secondary differences to distinguish accent variations.
 - Use tertiary differences to distinguish lettercase variations.

Either of these rules specifies a primary shift rule for the `'G'` character:

```

<p>G</p>

<p>\u0047</p>

```

- The `<i>` shift rule indicates that one character sorts identically to another. The following rules cause `'b'` to sort the same as `'a'`:

```

<reset>a</reset>

```

`<i>b</i>`

10.15 Character Set Configuration

The MySQL server has a compiled-in default character set and collation. To change these defaults, use the `--character-set-server` and `--collation-server` options when you start the server. See [Section 5.1.6, “Server Command Options”](#). The collation must be a legal collation for the default character set. To determine which collations are available for each character set, use the `SHOW COLLATION` statement or query the `INFORMATION_SCHEMA COLLATIONS` table.

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- If your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory), this can be fixed by using the `--character-sets-dir` option when you run the program. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets

[client]
character-sets-dir="C:/Program Files/MySQL/MySQL Server 5.5/share/charsets"
```

- If the character set is a complex character set that cannot be loaded dynamically, you must recompile the program with support for the character set.

For Unicode character sets, you can define collations without recompiling by using LDML notation. See [Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”](#).

- If the character set is a dynamic character set, but you do not have a configuration file for it, you should install the configuration file for the character set from a new MySQL distribution.
- If your character set index file (`Index.xml`) does not contain the name for the character set, your program displays an error message:

```
Character set 'charset_name' is not a compiled character set and is not
specified in the '/usr/share/mysql/charsets/Index.xml' file
```

To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` differs from `character_set_server` or `character_set_client`, and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with `--default-character-set=system_character_set`—that is, setting the client character set to match the system character set—should fix the problem.

10.16 MySQL Server Locale Support

The locale indicated by the `lc_time_names` system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()`, and `MONTHNAME()` functions.

`lc_time_names` does not affect the `STR_TO_DATE()` or `GET_FORMAT()` function.

The `lc_time_names` value does not affect the result from `FORMAT()`, but this function takes an optional third parameter that enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable.

Locale names have language and region subtags listed by IANA (<http://www.iana.org/assignments/language-subtag-registry>) such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting, but you can set the value at server startup, or set the `GLOBAL` value at runtime if you have privileges sufficient to set global system variables; see [Section 5.1.8.1, "System Variable Privileges"](#). Any client can examine the value of `lc_time_names` or set its `SESSION` value to affect the locale for its own connection.

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| en_US           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+-----+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| Friday                | January                  |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
| Friday Fri January Jan                    |
+-----+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| es_MX           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+-----+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| viernes                | enero                    |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
| viernes vie enero ene                    |
+-----+
1 row in set (0.00 sec)
```

The day or month name for each of the affected functions is converted from `utf8` to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

| Locale Value | Meaning |
|--------------------|-------------------------------|
| <code>ar_AE</code> | Arabic - United Arab Emirates |
| <code>ar_BH</code> | Arabic - Bahrain |
| <code>ar_DZ</code> | Arabic - Algeria |
| <code>ar_EG</code> | Arabic - Egypt |
| <code>ar_IN</code> | Arabic - India |
| <code>ar_IQ</code> | Arabic - Iraq |
| <code>ar_JO</code> | Arabic - Jordan |
| <code>ar_KW</code> | Arabic - Kuwait |
| <code>ar_LB</code> | Arabic - Lebanon |
| <code>ar_LY</code> | Arabic - Libya |
| <code>ar_MA</code> | Arabic - Morocco |
| <code>ar_OM</code> | Arabic - Oman |
| <code>ar_QA</code> | Arabic - Qatar |
| <code>ar_SA</code> | Arabic - Saudi Arabia |
| <code>ar_SD</code> | Arabic - Sudan |
| <code>ar_SY</code> | Arabic - Syria |
| <code>ar_TN</code> | Arabic - Tunisia |
| <code>ar_YE</code> | Arabic - Yemen |
| <code>be_BY</code> | Belarusian - Belarus |
| <code>bg_BG</code> | Bulgarian - Bulgaria |
| <code>ca_ES</code> | Catalan - Spain |
| <code>cs_CZ</code> | Czech - Czech Republic |
| <code>da_DK</code> | Danish - Denmark |
| <code>de_AT</code> | German - Austria |
| <code>de_BE</code> | German - Belgium |
| <code>de_CH</code> | German - Switzerland |
| <code>de_DE</code> | German - Germany |
| <code>de_LU</code> | German - Luxembourg |
| <code>el_GR</code> | Greek - Greece |
| <code>en_AU</code> | English - Australia |
| <code>en_CA</code> | English - Canada |
| <code>en_GB</code> | English - United Kingdom |
| <code>en_IN</code> | English - India |
| <code>en_NZ</code> | English - New Zealand |
| <code>en_PH</code> | English - Philippines |
| <code>en_US</code> | English - United States |
| <code>en_ZA</code> | English - South Africa |
| <code>en_ZW</code> | English - Zimbabwe |
| <code>es_AR</code> | Spanish - Argentina |

| Locale Value | Meaning |
|---------------------|------------------------------|
| es_BO | Spanish - Bolivia |
| es_CL | Spanish - Chile |
| es_CO | Spanish - Colombia |
| es_CR | Spanish - Costa Rica |
| es_DO | Spanish - Dominican Republic |
| es_EC | Spanish - Ecuador |
| es_ES | Spanish - Spain |
| es_GT | Spanish - Guatemala |

| 11.4.7 | Optimizing Spatial Analysis | 1131 |
| 11.4.8 | Creating Spatial Indexes | 1132 |
| 11.4.9 | Using Spatial Indexes | 1133 |
| 11.5 | Data Type Default Values | 1134 |
| 11.6 | Data Type Storage Requirements | 1136 |
| 11.7 | Choosing the Right Type for a Column | 1139 |
| 11.8 | Using Data Types from Other Database Engines | 1140 |

MySQL supports [SQL](#) data types in several categories: numeric types, date and time types, string (character and byte) types, and spatial types. This chapter provides an overview and more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overviews are intentionally brief. Consult the more detailed descriptions for additional information about particular data types, such as the permissible formats in which you can specify values.

Data type descriptions use these conventions:

- For integer types, *M* indicates the maximum display width. For floating-point and fixed-point types, *M* is the total number of digits that can be stored (the precision). For string types, *M* is the maximum length. The maximum permissible value of *M* depends on the data type.

- *D* applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than $M-2$.
- Square brackets ([and]) indicate optional parts of type definitions.

11.1 Numeric Data Types

MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (`INTEGER`, `SMALLINT`, `DECIMAL`, and `NUMERIC`), as well as the approximate numeric data types (`FLOAT`, `REAL`, and `DOUBLE PRECISION`). The keyword `INT` is a synonym for `INTEGER`, and the keywords `DEC` and `FIXED` are synonyms for `DECIMAL`. MySQL treats `DOUBLE` as a synonym for `DOUBLE PRECISION` (a nonstandard extension). MySQL also treats `REAL` as a synonym for `DOUBLE PRECISION` (a nonstandard variation), unless the `REAL_AS_FLOAT` SQL mode is enabled.

The `BIT` data type stores bit values and is supported for `MyISAM`, `MEMORY`, `InnoDB`, and `NDBCLUSTER` tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see [Section 11.1.7, “Out-of-Range and Overflow Handling”](#).

For information about storage requirements of the numeric data types, see [Section 11.6, “Data Type Storage Requirements”](#).

For descriptions of functions that operate on numeric values, see [Section 12.5, “Numeric Functions and Operators”](#). The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see [Section 12.5.1, “Arithmetic Operators”](#).

11.1.1 Numeric Data Type Syntax

For integer data types, *M* indicates the maximum display width. The maximum display width is 255. Display width is unrelated to the range of values a type can store, as described in [Section 11.1.6, “Numeric Type Attributes”](#).

For floating-point and fixed-point data types, *M* is the total number of digits that can be stored.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Numeric data types that permit the `UNSIGNED` attribute also permit `SIGNED`. However, these data types are signed by default, so the `SIGNED` attribute has no effect.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

Warning

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned unless the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled. See [Section 12.10, “Cast Functions and Operators”](#).

- `BIT[(M)]`

A bit-value type. *M* indicates the number of bits per value, from 1 to 64. The default is 1 if *M* is omitted.

- `TINYINT[(M)] [UNSIGNED] [ZEROFILL]`

A very small integer. The signed range is -128 to 127 . The unsigned range is 0 to 255 .

- `BOOL, BOOLEAN`

These types are synonyms for `TINYINT(1)`. A value of zero is considered false. Nonzero values are considered true:

```
mysql> SELECT IF(0, 'true', 'false');
+-----+
| IF(0, 'true', 'false') |
+-----+
| false                  |
+-----+

mysql> SELECT IF(1, 'true', 'false');
+-----+
| IF(1, 'true', 'false') |
+-----+
| true                   |
+-----+

mysql> SELECT IF(2, 'true', 'false');
+-----+
| IF(2, 'true', 'false') |
+-----+
| true                   |
+-----+
```

However, the values `TRUE` and `FALSE` are merely aliases for `1` and `0`, respectively, as shown here:

```
mysql> SELECT IF(0 = FALSE, 'true', 'false');
+-----+
| IF(0 = FALSE, 'true', 'false') |
+-----+
| true                            |
+-----+

mysql> SELECT IF(1 = TRUE, 'true', 'false');
+-----+
| IF(1 = TRUE, 'true', 'false') |
+-----+
| true                            |
+-----+

mysql> SELECT IF(2 = TRUE, 'true', 'false');
+-----+
| IF(2 = TRUE, 'true', 'false') |
+-----+
| false                           |
+-----+

mysql> SELECT IF(2 = FALSE, 'true', 'false');
+-----+
| IF(2 = FALSE, 'true', 'false') |
+-----+
| false                           |
+-----+
```

The last two statements display the results shown because `2` is equal to neither `1` nor `0`.

- `SMALLINT[(M)] [UNSIGNED] [ZEROFILL]`

A small integer. The signed range is `-32768` to `32767`. The unsigned range is `0` to `65535`.

- `MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]`

A medium-sized integer. The signed range is `-8388608` to `8388607`. The unsigned range is `0` to `16777215`.

- `INT[(M)] [UNSIGNED] [ZEROFILL]`

A normal-size integer. The signed range is `-2147483648` to `2147483647`. The unsigned range is `0` to `4294967295`.

- `INTEGER[(M)] [UNSIGNED] [ZEROFILL]`

This type is a synonym for `INT`.

- `BIGINT[(M)] [UNSIGNED] [ZEROFILL]`

A large integer. The signed range is `-9223372036854775808` to `9223372036854775807`. The unsigned range is `0` to `18446744073709551615`.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

Some things you should be aware of with respect to `BIGINT` columns:

- All arithmetic is done using signed `BIGINT` or `DOUBLE` values, so you should not use unsigned big integers larger than `9223372036854775807` (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a `BIGINT` value to a `DOUBLE`.

MySQL can handle `BIGINT` in the following cases:

- When using integers to store large unsigned values in a `BIGINT` column.
- In `MIN(col_name)` or `MAX(col_name)`, where `col_name` refers to a `BIGINT` column.
- When using operators (`+`, `-`, `*`, and so on) where both operands are integers.
- You can always store an exact integer value in a `BIGINT` column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The `-`, `+`, and `*` operators use `BIGINT` arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than `9223372036854775807`.
- `DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]`

A packed “exact” fixed-point number. `M` is the total number of digits (the precision) and `D` is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the `-` sign are not counted in `M`. If `D` is 0, values have no decimal point or fractional part. The maximum number of digits (`M`) for `DECIMAL` is 65. The maximum number of supported decimals (`D`) is 30. If `D` is omitted, the default is 0. If `M` is omitted, the default is 10.

`UNSIGNED`, if specified, disallows negative values.

All basic calculations (`+`, `-`, `*`, `/`) with `DECIMAL` columns are done with a precision of 65 digits.

- `DEC[(M[,D])] [UNSIGNED] [ZEROFILL], NUMERIC[(M[,D])] [UNSIGNED] [ZEROFILL], FIXED[(M[,D])] [UNSIGNED] [ZEROFILL]`

These types are synonyms for `DECIMAL`. The `FIXED` synonym is available for compatibility with other database systems.

- `FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]`

A small (single-precision) floating-point number. Permissible values are `-3.402823466E+38` to `-1.175494351E-38`, `0`, and `1.175494351E-38` to `3.402823466E+38`. These are the theoretical

limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of digits and D is the number of digits following the decimal point. If M and D are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

`FLOAT(M,D)` is a nonstandard MySQL extension.

`UNSIGNED`, if specified, disallows negative values.

Using `FLOAT` might give you some unexpected problems because all calculations in MySQL are done with double precision. See [Section B.4.4.7, “Solving Problems with No Matching Rows”](#).

- `FLOAT(p) [UNSIGNED] [ZEROFILL]`

A floating-point number. p represents the precision in bits, but MySQL uses this value only to determine whether to use `FLOAT` or `DOUBLE` for the resulting data type. If p is from 0 to 24, the data type becomes `FLOAT` with no M or D values. If p is from 25 to 53, the data type becomes `DOUBLE` with no M or D values. The range of the resulting column is the same as for the single-precision `FLOAT` or double-precision `DOUBLE` data types described earlier in this section.

`FLOAT(p)` syntax is provided for ODBC compatibility.

- `DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]`

A normal-size (double-precision) floating-point number. Permissible values are $-1.7976931348623157E+308$ to $-2.2250738585072014E-308$, 0 , and $2.2250738585072014E-308$ to $1.7976931348623157E+308$. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of digits and D is the number of digits following the decimal point. If M and D are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

`DOUBLE(M,D)` is a nonstandard MySQL extension.

`UNSIGNED`, if specified, disallows negative values.

- `DOUBLE PRECISION[(M,D)] [UNSIGNED] [ZEROFILL], REAL[(M,D)] [UNSIGNED] [ZEROFILL]`

These types are synonyms for `DOUBLE`. Exception: If the `REAL_AS_FLOAT` SQL mode is enabled, `REAL` is a synonym for `FLOAT` rather than `DOUBLE`.

11.1.2 Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT

MySQL supports the SQL standard integer types `INTEGER` (or `INT`) and `SMALLINT`. As an extension to the standard, MySQL also supports the integer types `TINYINT`, `MEDIUMINT`, and `BIGINT`. The following table shows the required storage and range for each integer type.

Table 11.1 Required Storage and Range for Integer Types Supported by MySQL

| Type | Storage (Bytes) | Minimum Value Signed | Minimum Value Unsigned | Maximum Value Signed | Maximum Value Unsigned |
|----------------------|-----------------|----------------------|------------------------|----------------------|------------------------|
| <code>TINYINT</code> | 1 | -128 | 0 | 127 | 255 |

| Type | Storage (Bytes) | Minimum Value Signed | Minimum Value Unsigned | Maximum Value Signed | Maximum Value Unsigned |
|------------------------|-----------------|----------------------|------------------------|----------------------|------------------------|
| <code>SMALLINT</code> | 2 | -32768 | 0 | 32767 | 65535 |
| <code>MEDIUMINT</code> | 3 | -8388608 | 0 | 8388607 | 16777215 |
| <code>INT</code> | 4 | -2147483648 | 0 | 2147483647 | 4294967295 |
| <code>BIGINT</code> | 8 | -2^{63} | 0 | $2^{63}-1$ | $2^{64}-1$ |

11.1.3 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC

The `DECIMAL` and `NUMERIC` types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, `NUMERIC` is implemented as `DECIMAL`, so the following remarks about `DECIMAL` apply equally to `NUMERIC`.

MySQL stores `DECIMAL` values in binary format. See [Section 12.19, “Precision Math”](#).

In a `DECIMAL` column declaration, the precision and scale can be (and usually is) specified. For example:

```
salary DECIMAL(5,2)
```

In this example, `5` is the precision and `2` is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that `DECIMAL(5,2)` be able to store any value with five digits and two decimals, so values that can be stored in the `salary` column range from `-999.99` to `999.99`.

In standard SQL, the syntax `DECIMAL(M)` is equivalent to `DECIMAL(M,0)`. Similarly, the syntax `DECIMAL` is equivalent to `DECIMAL(M,0)`, where the implementation is permitted to decide the value of `M`. MySQL supports both of these variant forms of `DECIMAL` syntax. The default value of `M` is 10.

If the scale is 0, `DECIMAL` values contain no decimal point or fractional part.

The maximum number of digits for `DECIMAL` is 65, but the actual range for a given `DECIMAL` column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

11.1.4 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE

The `FLOAT` and `DOUBLE` types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For `FLOAT`, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword `FLOAT` in parentheses; that is, `FLOAT(p)`. MySQL also supports this optional precision specification, but the precision value in `FLOAT(p)` is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision `FLOAT` column. A precision from 24 to 53 results in an 8-byte double-precision `DOUBLE` column.

MySQL permits a nonstandard syntax: `FLOAT(M,D)` or `REAL(M,D)` or `DOUBLE PRECISION(M,D)`. Here, `(M,D)` means that values can be stored with up to `M` digits in total, of which `D` digits may be after the decimal point. For example, a column defined as `FLOAT(7,4)` will look like `-999.9999` when displayed. MySQL performs rounding when storing values, so if you insert `999.00009` into a `FLOAT(7,4)` column, the approximate result is `999.0001`.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see [Section B.4.4.8, “Problems with Floating-Point Values”](#)

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of digits.

11.1.5 Bit-Value Type - BIT

The `BIT` data type is used to store bit values. A type of `BIT(M)` enables storage of M -bit values. M can range from 1 to 64.

To specify bit values, `b'value'` notation can be used. `value` is a binary value written using zeros and ones. For example, `b'111'` and `b'10000000'` represent 7 and 128, respectively. See [Section 9.1.5, “Bit-Value Literals”](#).

If you assign a value to a `BIT(M)` column that is less than M bits long, the value is padded on the left with zeros. For example, assigning a value of `b'101'` to a `BIT(6)` column is, in effect, the same as assigning `b'000101'`.

NDB Cluster. The maximum combined size of all `BIT` columns used in a given `NDB` table must not exceed 4096 bits.

11.1.6 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, `INT(4)` specifies an `INT` with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used is up to the application.)

The display width does *not* constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as `SMALLINT(3)` has the usual `SMALLINT` range of `-32768` to `32767`, and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) `ZEROFILL` attribute, the default padding of spaces is replaced with zeros. For example, for a column declared as `INT(4) ZEROFILL`, a value of 5 is retrieved as `0005`.

Note

The `ZEROFILL` attribute is ignored for columns involved in expressions or `UNION` queries.

If you store values larger than the display width in an integer column that has the `ZEROFILL` attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

All integer types can have an optional (nonstandard) `UNSIGNED` attribute. An unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the column. For example, if an `INT` column is `UNSIGNED`, the size of the column's range is the same but its endpoints shift up, from `-2147483648` and `2147483647` to `0` and `4294967295`.

Floating-point and fixed-point types also can be `UNSIGNED`. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute.

Integer or floating-point data types can have the `AUTO_INCREMENT` attribute. When you insert a value of `NULL` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. (`AUTO_INCREMENT` sequences begin with 1.)

Storing 0 into an `AUTO_INCREMENT` column has the same effect as storing `NULL`, unless the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled.

Inserting `NULL` to generate `AUTO_INCREMENT` values requires that the column be declared `NOT NULL`. If the column is declared `NULL`, inserting `NULL` stores a `NULL`. When you insert any other value into an `AUTO_INCREMENT` column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the inserted value.

As of MySQL 5.5.29, negative values for `AUTO_INCREMENT` columns are not supported.

11.1.7 Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.
- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the column data type range and stores the resulting value instead.

When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Suppose that a table `t1` has this definition:

```
CREATE TABLE t1 (i1 TINYINT, i2 TINYINT UNSIGNED);
```

With strict SQL mode enabled, an out of range error occurs:

```
mysql> SET sql_mode = 'TRADITIONAL';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1
mysql> SELECT * FROM t1;
Empty set (0.00 sec)
```

With strict SQL mode not enabled, clipping with warnings occurs:

```
mysql> SET sql_mode = '';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1264 | Out of range value for column 'i1' at row 1 |
| Warning | 1264 | Out of range value for column 'i2' at row 1 |
+-----+-----+-----+
mysql> SELECT * FROM t1;
+-----+-----+
| i1 | i2 |
+-----+-----+
| 127 | 255 |
+-----+-----+
```

```
+-----+-----+
```

When strict SQL mode is not enabled, column-assignment conversions that occur due to clipping are reported as warnings for `ALTER TABLE`, `LOAD DATA`, `UPDATE`, and multiple-row `INSERT` statements. In strict mode, these statements fail, and some or all the values are not inserted or changed, depending on whether the table is a transactional table and other factors. For details, see [Section 5.1.10, “Server SQL Modes”](#).

Overflow during numeric expression evaluation results in an error. For example, the largest signed `BIGINT` value is 9223372036854775807, so the following expression produces an error:

```
mysql> SELECT 9223372036854775807 + 1;
ERROR 1690 (22003): BIGINT value is out of range in '(9223372036854775807 + 1)'
```

To enable the operation to succeed in this case, convert the value to unsigned;

```
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-----+-----+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
+-----+-----+
|                               9223372036854775808 |
+-----+-----+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because `DECIMAL` values have a larger range than integers:

```
mysql> SELECT 9223372036854775807.0 + 1;
+-----+-----+
| 9223372036854775807.0 + 1 |
+-----+-----+
|           9223372036854775808.0 |
+-----+-----+
```

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+-----+
|                       -1 |
+-----+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

11.2 Date and Time Data Types

The date and time data types for representing temporal values are `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`. Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The `TIMESTAMP` type has special automatic updating behavior, described in [Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP”](#).

For information about storage requirements of the temporal data types, see [Section 11.6, “Data Type Storage Requirements”](#).

For descriptions of functions that operate on temporal values, see [Section 12.6, “Date and Time Functions”](#).

Keep in mind these general considerations when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see [Section 9.1.3, “Date and Time Literals”](#). It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.
- Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, '98-09-04'), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, '09-04-98', '04-09-98'). To convert strings in other orders to year-month-day order, the `STR_TO_DATE()` function may be useful.
- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
 - Year values in the range 70–99 become 1970–1999.
 - Year values in the range 00–69 become 2000–2069.

See also [Section 11.2.9, “2-Digit Years in Dates”](#).

- Conversion of values from one temporal type to another occurs according to the rules in [Section 11.2.8, “Conversion Between Date and Time Types”](#).
- MySQL automatically converts a date or time value to a number if the value is used in numeric context and vice versa.
- By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range `TIME` values are clipped to the appropriate endpoint of the `TIME` range.
- By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See [Section 5.1.10, “Server SQL Modes”](#).) You can get MySQL to accept certain dates, such as '2009-11-31', by enabling the `ALLOW_INVALID_DATES` SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.
- MySQL permits you to store dates where the day or month and day are zero in a `DATE` or `DATETIME` column. This is useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as '2009-00-00' or '2009-01-00'. However, with dates such as these, you should not expect to get correct results for functions such as `DATE_SUB()` or `DATE_ADD()` that require complete dates. To disallow zero month or day parts in dates, enable the `NO_ZERO_IN_DATE` SQL mode.
- MySQL permits you to store a “zero” value of '0000-00-00' as a “dummy date.” In some cases, this is more convenient than using `NULL` values, and uses less data and index space. To disallow '0000-00-00', enable the `NO_ZERO_DATE` SQL mode.
- “Zero” date or time values used through Connector/ODBC are converted automatically to `NULL` because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values '0' or 0, which are easier to write. For temporal types that include a date part

([DATE](#), [DATETIME](#), and [TIMESTAMP](#)), use of these values may produce warning or errors. The precise behavior depends on which, if any, of the strict and [NO_ZERO_DATE](#) SQL modes are enabled; see [Section 5.1.10, “Server SQL Modes”](#).

| Data Type | “Zero” Value |
|---------------------------|-----------------------|
| DATE | '0000-00-00' |
| TIME | '00:00:00' |
| DATETIME | '0000-00-00 00:00:00' |
| TIMESTAMP | '0000-00-00 00:00:00' |
| YEAR | 0000 |

11.2.1 Date and Time Data Type Syntax

The date and time data types for representing temporal values are [DATE](#), [TIME](#), [DATETIME](#), [TIMESTAMP](#), and [YEAR](#).

For the [DATE](#) and [DATETIME](#) range descriptions, “supported” means that although earlier values might work, there is no guarantee.

- [DATE](#)

A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays [DATE](#) values in 'YYYY-MM-DD' format, but permits assignment of values to [DATE](#) columns using either strings or numbers.

- [DATETIME](#)

A date and time combination. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'. MySQL displays [DATETIME](#) values in 'YYYY-MM-DD hh:mm:ss' format, but permits assignment of values to [DATETIME](#) columns using either strings or numbers.

- [TIMESTAMP](#)

A timestamp. The range is '1970-01-01 00:00:01' UTC to '2038-01-19 03:14:07' UTC. [TIMESTAMP](#) values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A [TIMESTAMP](#) cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the “zero” [TIMESTAMP](#) value.

Unless specified otherwise, the first [TIMESTAMP](#) column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes [TIMESTAMP](#) useful for recording the timestamp of an [INSERT](#) or [UPDATE](#) operation. You can also set any [TIMESTAMP](#) column to the current date and time by assigning it a [NULL](#) value, unless it has been defined with the [NULL](#) attribute to permit [NULL](#) values. The automatic initialization and updating to the current date and time can be specified using [DEFAULT CURRENT_TIMESTAMP](#) and [ON UPDATE CURRENT_TIMESTAMP](#) clauses, as described in [Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP”](#).

- [TIME](#)

A time. The range is '-838:59:59' to '838:59:59'. MySQL displays [TIME](#) values in 'hh:mm:ss' format, but permits assignment of values to [TIME](#) columns using either strings or numbers.

- [YEAR](#)[(2|4)]

A year in 2-digit or 4-digit format. The default is 4-digit format. [YEAR\(2\)](#) or [YEAR\(4\)](#) differ in display format, but have the same range of values. In 4-digit format, values display as 1901 to 2155, or

0000. In 2-digit format, values display as 70 to 69, representing years from 1970 to 2069. MySQL displays `YEAR` values in `YYYY` or `YY` format, but permits assignment of values to `YEAR` columns using either strings or numbers.

Note

The `YEAR(2)` data type has certain issues that you should consider before choosing to use it. As of MySQL 5.5.27, `YEAR(2)` is deprecated. For more information, see [Section 11.2.5, “2-Digit YEAR\(2\) Limitations and Migrating to 4-Digit YEAR”](#).

For additional information about `YEAR` display format and interpretation of input values, see [Section 11.2.4, “The YEAR Type”](#).

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Note

The MySQL server can be run with the `MAXDB` SQL mode enabled. In this case, `TIMESTAMP` is identical with `DATETIME`. If this mode is enabled at the time that a table is created, `TIMESTAMP` columns are created as `DATETIME` columns. As a result, such columns use `DATETIME` display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See [Section 5.1.10, “Server SQL Modes”](#).

11.2.2 The DATE, DATETIME, and TIMESTAMP Types

The `DATE`, `DATETIME`, and `TIMESTAMP` types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes `DATE`, `DATETIME`, and `TIMESTAMP` values in several formats, described in [Section 9.1.3, “Date and Time Literals”](#). For the `DATE` and `DATETIME` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The `DATE` type is used for values with a date part but no time part. MySQL retrieves and displays `DATE` values in `'YYYY-MM-DD'` format. The supported range is `'1000-01-01'` to `'9999-12-31'`.

The `DATETIME` type is used for values that contain both date and time parts. MySQL retrieves and displays `DATETIME` values in `'YYYY-MM-DD hh:mm:ss'` format. The supported range is `'1000-01-01 00:00:00'` to `'9999-12-31 23:59:59'`.

The `TIMESTAMP` data type is used for values that contain both date and time parts. `TIMESTAMP` has a range of `'1970-01-01 00:00:01'` UTC to `'2038-01-19 03:14:07'` UTC.

MySQL converts `TIMESTAMP` values from the current time zone to UTC for storage, and back from UTC to the current time zone for retrieval. (This does not occur for other types such as `DATETIME`.) By default, the current time zone for each connection is the server's time. The time zone can be set on a per-connection basis. As long as the time zone setting remains constant, you get back the same value you store. If you store a `TIMESTAMP` value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the `time_zone` system variable. For more information, see [Section 5.1.12, “MySQL Server Time Zone Support”](#).

The `TIMESTAMP` data type offers automatic initialization and updating to the current date and time. For more information, see [Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP”](#).

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into `DATETIME` or `TIMESTAMP` columns. For information about fractional seconds support in MySQL, see [Section 11.2.7, “Fractional Seconds in Time Values”](#).

Invalid `DATE`, `DATETIME`, or `TIMESTAMP` values are converted to the “zero” value of the appropriate type (`'0000-00-00'` or `'0000-00-00 00:00:00'`), if the SQL mode permits this conversion. The precise behavior depends on which if any of strict SQL mode and the `NO_ZERO_DATE` SQL mode are enabled; see [Section 5.1.10, “Server SQL Modes”](#).

Be aware of certain properties of date value interpretation in MySQL:

- MySQL permits a “relaxed” format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as `'10:11:12'` might look like a time value because of the `:`, but is interpreted as the year `'2010-11-12'` if used in date context. The value `'10:45:15'` is converted to `'0000-00-00'` because `'45'` is not a valid month.
- The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`. See [Section 5.1.10, “Server SQL Modes”](#), for more information.
- MySQL does not accept `TIMESTAMP` values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value `'0000-00-00 00:00:00'`, if the SQL mode permits this value. The precise behavior depends on which if any of strict SQL mode and the `NO_ZERO_DATE` SQL mode are enabled; see [Section 5.1.10, “Server SQL Modes”](#).
- `CAST()` treats a `TIMESTAMP` value as a string when not selecting from a table. (This is true even if you specify `FROM DUAL`.) See [Section 12.10, “Cast Functions and Operators”](#).
- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
 - Year values in the range `00-69` become `2000-2069`.
 - Year values in the range `70-99` become `1970-1999`.

See also [Section 11.2.9, “2-Digit Years in Dates”](#).

Note

The MySQL server can be run with the `MAXDB` SQL mode enabled. In this case, `TIMESTAMP` is identical with `DATETIME`. If this mode is enabled at the time that a table is created, `TIMESTAMP` columns are created as `DATETIME` columns. As a result, such columns use `DATETIME` display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See [Section 5.1.10, “Server SQL Modes”](#).

11.2.3 The TIME Type

MySQL retrieves and displays `TIME` values in `'hh:mm:ss'` format (or `'hhh:mm:ss'` format for large hours values). `TIME` values may range from `'-838:59:59'` to `'838:59:59'`. The hours part may be so large because the `TIME` type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes `TIME` values in several formats, described in [Section 9.1.3, “Date and Time Literals”](#). Some of these formats can include a trailing fractional seconds part in up to microseconds (6

digits) precision. Although this fractional part is recognized, it is discarded from values stored into `TIME` columns. For information about fractional seconds support in MySQL, see [Section 11.2.7, “Fractional Seconds in Time Values”](#).

Be careful about assigning abbreviated values to a `TIME` column. MySQL interprets abbreviated `TIME` values with colons as time of the day. That is, `'11:12'` means `'11:12:00'`, not `'00:11:12'`. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of `'1112'` and `1112` as meaning `'11:12:00'` (12 minutes after 11 o'clock), but MySQL interprets them as `'00:11:12'` (11 minutes, 12 seconds). Similarly, `'12'` and `12` are interpreted as `'00:00:12'`.

By default, values that lie outside the `TIME` range but are otherwise valid are clipped to the closest endpoint of the range. For example, `'-850:00:00'` and `'850:00:00'` are converted to `'-838:59:59'` and `'838:59:59'`. Invalid `TIME` values are converted to `'00:00:00'`. Note that because `'00:00:00'` is itself a valid `TIME` value, there is no way to tell, from a value of `'00:00:00'` stored in a table, whether the original value was specified as `'00:00:00'` or whether it was invalid.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See [Section 5.1.10, “Server SQL Modes”](#).

11.2.4 The YEAR Type

The `YEAR` type is a 1-byte type used to represent year values. It can be declared as `YEAR` with an implicit display width of 4 characters, or as `YEAR(4)` or `YEAR(2)` with an explicit display width of 4 or 2 characters.

Note

The 2-digit `YEAR(2)` data type has certain issues that you should consider before choosing to use it. As of MySQL 5.5.27, `YEAR(2)` is deprecated. For more information, see [Section 11.2.5, “2-Digit YEAR\(2\) Limitations and Migrating to 4-Digit YEAR”](#).

`YEAR/YEAR(4)` and `YEAR(2)` differ in display format, but have the same range of values. For 4-digit format, MySQL displays `YEAR` values in `YYYY` format, with a range of `1901` to `2155`, and `0000`. For 2-digit format, MySQL displays only the last (least significant) 2 digits; for example, `70` (1970 or 2070) or `69` (2069).

`YEAR` accepts input values in a variety of formats:

- As 4-digit strings in the range `'1901'` to `'2155'`.
- As 4-digit numbers in the range `1901` to `2155`.
- As 1- or 2-digit strings in the range `'0'` to `'99'`. MySQL converts values in the ranges `'0'` to `'69'` and `'70'` to `'99'` to `YEAR` values in the ranges `2000` to `2069` and `1970` to `1999`.
- As 1- or 2-digit numbers in the range `0` to `99`. MySQL converts values in the ranges `1` to `69` and `70` to `99` to `YEAR` values in the ranges `2001` to `2069` and `1970` to `1999`.

Inserting a numeric `0` has different effects for `YEAR/YEAR(4)` and `YEAR(2)`:

- For `YEAR/YEAR(4)`, the result has a display value of `0000` and an internal value of `0000`. To specify zero and have it be interpreted as `2000`, specify it as a string `'0'` or `'00'`.
- For `YEAR(2)`, the result has a display value of `00` and an internal value of `2000`.
- As the result of functions that return a value that is acceptable in `YEAR` context, such as `NOW()`.

If strict SQL mode is not enabled, MySQL converts invalid `YEAR` values to `0000`. In strict SQL mode, attempting to insert an invalid `YEAR` value produces an error.

See also [Section 11.2.9, “2-Digit Years in Dates”](#).

11.2.5 2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR

This section describes problems that can occur when using the 2-digit `YEAR(2)` data type and provides information about converting existing `YEAR(2)` columns to 4-digit year-valued columns, which can be declared as `YEAR` with an implicit display width of 4 characters, or equivalently as `YEAR(4)` with an explicit display width.

Although the internal range of values for `YEAR/YEAR(4)` and the deprecated `YEAR(2)` type is the same (1901 to 2155, and 0000), the display width for `YEAR(2)` makes that type inherently ambiguous because displayed values indicate only the last two digits of the internal values and omit the century digits. The result can be a loss of information under certain circumstances. For this reason, avoid using `YEAR(2)` in your applications and use `YEAR/YEAR(4)` wherever you need a year-valued data type. Note that conversion is required at some point because support for `YEAR` data types with display values other than 4, most notably `YEAR(2)`, is reduced as of MySQL 5.6.6 and is removed entirely in MySQL 5.7.

YEAR(2) Limitations

Issues with the `YEAR(2)` data type include ambiguity of displayed values, and possible loss of information when values are dumped and reloaded or converted to strings.

- Displayed `YEAR(2)` values can be ambiguous. It is possible for up to three `YEAR(2)` values that have different internal values to have the same displayed value, as the following example demonstrates:

```
mysql> CREATE TABLE t (y2 YEAR(2), y4 YEAR);
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> INSERT INTO t (y2) VALUES(1912),(2012),(2112);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> UPDATE t SET y4 = y2;
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0

mysql> SELECT * FROM t;
+-----+-----+
| y2   | y4   |
+-----+-----+
| 12   | 1912 |
| 12   | 2012 |
| 12   | 2112 |
+-----+-----+
3 rows in set (0.00 sec)
```

- If you use `mysqldump` to dump the table created in the preceding example, the dump file represents all `y2` values using the same 2-digit representation (12). If you reload the table from the dump file, all resulting rows have internal value 2012 and display value 12, thus losing the distinctions between them.
- Conversion of a 2-digit or 4-digit `YEAR` data value to string form uses the data type display width. Suppose that a `YEAR(2)` column and a `YEAR/YEAR(4)` column both contain the value 1970. Assigning each column to a string results in a value of '70' or '1970', respectively. That is, loss of information occurs for conversion from `YEAR(2)` to string.
- Values outside the range from 1970 to 2069 are stored incorrectly when inserted into a `YEAR(2)` column in a `CSV` table. For example, inserting 2211 results in a display value of 11 but an internal value of 2011.

To avoid these problems, use the 4-digit `YEAR` or `YEAR(4)` data type rather than the 2-digit `YEAR(2)` data type. Suggestions regarding migration strategies appear later in this section.

Migrating from `YEAR(2)` to 4-Digit `YEAR`

To convert 2-digit `YEAR(2)` columns to 4-digit `YEAR` columns, use `ALTER TABLE`. Suppose that a table `t1` has this definition:

```
CREATE TABLE t1 (ycol YEAR(2) NOT NULL DEFAULT '70');
```

Modify the column using `ALTER TABLE` as follows. Remember to include any column attributes such as `NOT NULL` or `DEFAULT`:

```
ALTER TABLE t1 MODIFY ycol YEAR NOT NULL DEFAULT '1970';
```

The `ALTER TABLE` statement converts the table without changing `YEAR(2)` values. If the server is a replication master, the `ALTER TABLE` statement replicates to slaves and makes the corresponding table change on each one.

One migration method should be avoided: Do not dump your data with `mysqldump` and reload the dump file after upgrading. That has the potential to change `YEAR(2)` values, as described previously.

A migration from 2-digit `YEAR(2)` columns to 4-digit `YEAR` columns should also involve examining application code for the possibility of changed behavior under conditions such as these:

- Code that expects selecting a `YEAR` column to produce exactly two digits.
- Code that does not account for different handling for inserts of numeric `0`: Inserting `0` into `YEAR(2)` or `YEAR(4)` results in an internal value of `2000` or `0000`, respectively.

11.2.6 Automatic Initialization and Updating for `TIMESTAMP`

Note

In older versions of MySQL (prior to 4.1), the properties of the `TIMESTAMP` data type differed significantly in several ways from what is described in this section (see the *MySQL 3.23, 4.0, 4.1 Reference Manual* for details); these include syntax extensions which are deprecated in MySQL 5.1, and no longer supported in MySQL 5.5. This has implications for performing a dump and restore or replicating between MySQL Server versions. If you are using columns that are defined using the old `TIMESTAMP(N)` syntax, see [Section 2.11.3, “Changes in MySQL 5.5”](#), prior to upgrading to MySQL 5.5.

The `TIMESTAMP` data type offers automatic initialization and updating to the current date and time (that is, the current timestamp). You can choose whether to use these properties and which column should have them:

- One `TIMESTAMP` column in a table can have the current timestamp as the default value for initializing the column, as the auto-update value, or both. It is not possible to have the current timestamp be the default value for one column and the auto-update value for another column.
- If the column is auto-initialized, it is set to the current timestamp for inserted rows that specify no value for the column.
- If the column is auto-updated, it is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. The column remains unchanged if all other columns are set to their current values. To prevent the column from updating when other columns change, explicitly set it to its current value. To update the column even when other columns do not change, explicitly set it to the value it should have (for example, set it to `CURRENT_TIMESTAMP`).

In addition, you can initialize or update any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

To specify automatic properties, use the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms for `CURRENT_TIMESTAMP` have the same meaning as `CURRENT_TIMESTAMP`. These are `CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, and `LOCALTIMESTAMP()`.

Use of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` is specific to `TIMESTAMP`. The `DEFAULT` clause also can be used to specify a constant (nonautomatic) default value (for example, `DEFAULT 0` or `DEFAULT '2000-01-01 00:00:00'`).

Note

The following examples use `DEFAULT 0`, a default that can produce warnings or errors depending on whether strict SQL mode or the `NO_ZERO_DATE` SQL mode is enabled. Be aware that the `TRADITIONAL` SQL mode includes strict mode and `NO_ZERO_DATE`. See [Section 5.1.10, “Server SQL Modes”](#).

The following rules describe the possibilities for defining the first `TIMESTAMP` column in a table with the current timestamp for both the default and auto-update values, for one but not the other, or for neither:

- With both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP`, the column has the current timestamp for its default value and is automatically updated to the current timestamp.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
);
```

- With neither `DEFAULT CURRENT_TIMESTAMP` nor `ON UPDATE CURRENT_TIMESTAMP`, it is the same as specifying both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP`.

```
CREATE TABLE t1 (
  ts TIMESTAMP
);
```

- With a `DEFAULT` clause but no `ON UPDATE CURRENT_TIMESTAMP` clause, the column has the given default value and is not automatically updated to the current timestamp.

The default depends on whether the `DEFAULT` clause specifies `CURRENT_TIMESTAMP` or a constant value. With `CURRENT_TIMESTAMP`, the default is the current timestamp.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP
);
```

With a constant, the default is the given value. In this case, the column has no automatic properties at all.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT 0
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause and a constant `DEFAULT` clause, the column is automatically updated to the current timestamp and has the given constant default value.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause but no `DEFAULT` clause, the column is automatically updated to the current timestamp. The default is 0 unless the column is defined with the `NULL` attribute, in which case the default is `NULL`.

```
CREATE TABLE t1 (
  ts TIMESTAMP ON UPDATE CURRENT_TIMESTAMP      -- default 0
);
```

```
CREATE TABLE t2 (
  ts TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP -- default NULL
);
```

It need not be the first `TIMESTAMP` column in a table that is automatically initialized or updated to the current timestamp. However, to specify automatic initialization or updating for a different `TIMESTAMP` column, you must suppress the automatic properties for the first one. Then, for the other `TIMESTAMP` column, the rules for the `DEFAULT` and `ON UPDATE` clauses are the same as for the first `TIMESTAMP` column, except that if you omit both clauses, no automatic initialization or updating occurs.

To suppress automatic properties for the first `TIMESTAMP` column, do either of the following:

- Define the column with a `DEFAULT` clause that specifies a constant default value.
- Specify the `NULL` attribute. This also causes the column to permit `NULL` values, which means that you cannot assign the current timestamp by setting the column to `NULL`. Assigning `NULL` sets the column to `NULL`.

Consider these table definitions:

```
CREATE TABLE t1 (
  ts1 TIMESTAMP DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t2 (
  ts1 TIMESTAMP NULL,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t3 (
  ts1 TIMESTAMP NULL DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
```

The tables have these properties:

- In each table definition, the first `TIMESTAMP` column has no automatic initialization or updating.
- The tables differ in how the `ts1` column handles `NULL` values. For `t1`, `ts1` is `NOT NULL` and assigning it a value of `NULL` sets it to the current timestamp. For `t2` and `t3`, `ts1` permits `NULL` and assigning it a value of `NULL` sets it to `NULL`.
- `t2` and `t3` differ in the default value for `ts1`. For `t2`, `ts1` is defined to permit `NULL`, so the default is also `NULL` in the absence of an explicit `DEFAULT` clause. For `t3`, `ts1` permits `NULL` but has an explicit default of 0.

TIMESTAMP Initialization and the `NULL` Attribute

By default, `TIMESTAMP` columns are `NOT NULL`, cannot contain `NULL` values, and assigning `NULL` assigns the current timestamp. To permit a `TIMESTAMP` column to contain `NULL`, explicitly declare it with the `NULL` attribute. In this case, the default value also becomes `NULL` unless overridden with a `DEFAULT` clause that specifies a different default value. `DEFAULT NULL` can be used to explicitly specify `NULL` as the default value. (For a `TIMESTAMP` column not declared with the `NULL` attribute, `DEFAULT NULL` is invalid.) If a `TIMESTAMP` column permits `NULL` values, assigning `NULL` sets it to `NULL`, not to the current timestamp.

The following table contains several `TIMESTAMP` columns that permit `NULL` values:

```
CREATE TABLE t
(
  ts1 TIMESTAMP NULL DEFAULT NULL,
  ts2 TIMESTAMP NULL DEFAULT 0,
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
);
```

A `TIMESTAMP` column that permits `NULL` values does *not* take on the current timestamp at insert time except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP` and no value is specified for the column
- `CURRENT_TIMESTAMP` or any of its synonyms such as `NOW()` is explicitly inserted into the column

In other words, a `TIMESTAMP` column defined to permit `NULL` values auto-initializes only if its definition includes `DEFAULT CURRENT_TIMESTAMP`:

```
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

If the `TIMESTAMP` column permits `NULL` values but its definition does not include `DEFAULT CURRENT_TIMESTAMP`, you must explicitly insert a value corresponding to the current date and time. Suppose that tables `t1` and `t2` have these definitions:

```
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL);
```

To set the `TIMESTAMP` column in either table to the current timestamp at insert time, explicitly assign it that value. For example:

```
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
INSERT INTO t1 VALUES (NOW());
```

11.2.7 Fractional Seconds in Time Values

A trailing fractional seconds part is permissible for temporal values in contexts such as literal values, and in the arguments to or return values from some temporal functions. Example:

```
mysql> SELECT MICROSECOND('2010-12-10 14:12:09.019473');
+-----+
| MICROSECOND('2010-12-10 14:12:09.019473') |
+-----+
|                                     19473 |
+-----+
```

However, when MySQL stores a value into a column of any temporal data type, it discards any fractional part and does not store it.

11.2.8 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although `DATE`, `DATETIME`, and `TIMESTAMP` values all can be specified using the same set of formats, the types do not all have the same range of values. `TIMESTAMP` values cannot be earlier than 1970 UTC or later than '2038-01-19 03:14:07' UTC. This means that a date such as '1968-01-01', while valid as a `DATE` or `DATETIME` value, is not valid as a `TIMESTAMP` value and is converted to 0.

Conversion of `DATE` values:

- Conversion to a `DATETIME` or `TIMESTAMP` value adds a time part of '00:00:00' because the `DATE` value contains no time information.
- Conversion to a `TIME` value is not useful; the result is '00:00:00'.

Conversion of `DATETIME` and `TIMESTAMP` values:

- Conversion to a `DATE` value discards the time part because the `DATE` type contains no time information.
- Conversion to a `TIME` value discards the date part because the `TIME` type contains no date information.

Conversion of `TIME` values:

MySQL converts a time value to a date or date-and-time value by parsing the string value of the time as a date or date-and-time. This is unlikely to be useful. For example, `'23:12:31'` interpreted as a date becomes `'2023-12-31'`. Time values not valid as dates become `'0000-00-00'` or `NULL`.

Explicit conversion can be used to override implicit conversion. For example, in comparison of `DATE` and `DATETIME` values, the `DATE` value is coerced to the `DATETIME` type by adding a time part of `'00:00:00'`. To perform the comparison by ignoring the time part of the `DATETIME` value instead, use the `CAST()` function in the following way:

```
date_col = CAST(datetime_col AS DATE)
```

Conversion of `TIME` or `DATETIME` values to numeric form (for example, by adding `+0`) results in a double-precision value with a microseconds part of `.000000`:

```
mysql> SELECT CURTIME(), CURTIME()+0;
+-----+-----+
| CURTIME() | CURTIME()+0 |
+-----+-----+
| 10:41:36 | 104136.000000 |
+-----+-----+
mysql> SELECT NOW(), NOW()+0;
+-----+-----+
| NOW() | NOW()+0 |
+-----+-----+
| 2007-11-30 10:41:47 | 20071130104147.000000 |
+-----+-----+
```

11.2.9 2-Digit Years in Dates

Date values with 2-digit years are ambiguous because the century is unknown. Such values must be interpreted into 4-digit form because MySQL stores years internally using 4 digits.

For `DATETIME`, `DATE`, and `TIMESTAMP` types, MySQL interprets dates specified with ambiguous year values using these rules:

- Year values in the range `00–69` become `2000–2069`.
- Year values in the range `70–99` become `1970–1999`.

For `YEAR`, the rules are the same, with this exception: A numeric `00` inserted into `YEAR(4)` results in `0000` rather than `2000`. To specify zero for `YEAR(4)` and have it be interpreted as `2000`, specify it as a string `'0'` or `'00'`.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing 4-digit year values.

`ORDER BY` properly sorts `YEAR` values that have 2-digit years.

Some functions like `MIN()` and `MAX()` convert a `YEAR` to a number. This means that a value with a 2-digit year does not work properly with these functions. The fix in this case is to convert the `YEAR` to 4-digit year format.

11.3 String Data Types

The string data types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`.

For information about storage requirements of the string data types, see [Section 11.6, “Data Type Storage Requirements”](#).

For descriptions of functions that operate on string values, see [Section 12.7, “String Functions and Operators”](#).

11.3.1 String Data Type Syntax

The string data types are [CHAR](#), [VARCHAR](#), [BINARY](#), [VARBINARY](#), [BLOB](#), [TEXT](#), [ENUM](#), and [SET](#).

In some cases, MySQL may change a string column to a type different from that given in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. See [Section 13.1.17.7, “Silent Column Specification Changes”](#).

For definitions of character string columns ([CHAR](#), [VARCHAR](#), and the [TEXT](#) types), MySQL interprets length specifications in character units. For definitions of binary string columns ([BINARY](#), [VARBINARY](#), and the [BLOB](#) types), MySQL interprets length specifications in byte units.

Column definitions for character string data types ([CHAR](#), [VARCHAR](#), the [TEXT](#) types, [ENUM](#), [SET](#), and any synonyms) can specify the column character set and collation:

- [CHARACTER SET](#) specifies the character set. If desired, a collation for the character set can be specified with the [COLLATE](#) attribute, along with any other attributes. For example:

```
CREATE TABLE t
(
  c1 VARCHAR(20) CHARACTER SET utf8,
  c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);
```

This table definition creates a column named `c1` that has a character set of `utf8` with the default collation for that character set, and a column named `c2` that has a character set of `latin1` and a case-sensitive (`_cs`) collation.

The rules for assigning the character set and collation when either or both of [CHARACTER SET](#) and the [COLLATE](#) attribute are missing are described in [Section 10.3.5, “Column Character Set and Collation”](#).

[CHARSET](#) is a synonym for [CHARACTER SET](#).

- Specifying the [CHARACTER SET binary](#) attribute for a character string data type causes the column to be created as the corresponding binary string data type: [CHAR](#) becomes [BINARY](#), [VARCHAR](#) becomes [VARBINARY](#), and [TEXT](#) becomes [BLOB](#). For the [ENUM](#) and [SET](#) data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

- The [BINARY](#) attribute is a nonstandard MySQL extension that is shorthand for specifying the binary (`_bin`) collation of the column character set (or of the table default character set if no column character set is specified). In this case, comparison and sorting are based on numeric character code values. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET latin1 BINARY,
```

```
c2 TEXT BINARY
) CHARACTER SET utf8mb4;
```

The resulting table has this definition:

```
CREATE TABLE t (
  c1 VARCHAR(10) CHARACTER SET latin1 COLLATE latin1_bin,
  c2 TEXT CHARACTER SET utf8mb4 COLLATE utf8mb4_bin
) CHARACTER SET utf8mb4;
```

- The `ASCII` attribute is shorthand for `CHARACTER SET latin1`.
- The `UNICODE` attribute is shorthand for `CHARACTER SET ucs2`.

Character column comparison and sorting are based on the collation assigned to the column. For the `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET` data types, you can declare a column with a binary (`_bin`) collation or the `BINARY` attribute to cause comparison and sorting to use the underlying character code values rather than a lexical ordering.

For additional information about use of character sets in MySQL, see [Chapter 10, Character Sets, Collations, Unicode](#).

- `[NATIONAL] CHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A fixed-length string that is always right-padded with spaces to the specified length when stored. *M* represents the column length in characters. The range of *M* is 0 to 255. If *M* is omitted, the length is 1.

Note

Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

`CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. [Section 10.3.7, “The National Character Set”](#).

The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you must be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `''` (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A variable-length string. *M* represents the maximum column length in characters. The range of *M* is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. For example, `utf8` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters. See [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

MySQL stores `VARCHAR` values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A `VARCHAR` column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

Note

MySQL follows the standard SQL specification, and does *not* remove trailing spaces from `VARCHAR` values.

`VARCHAR` is shorthand for `CHARACTER VARYING`. `NATIONAL VARCHAR` is the standard SQL way to define that a `VARCHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. [Section 10.3.7, “The National Character Set”](#). `NVARCHAR` is shorthand for `NATIONAL VARCHAR`.

- `BINARY [(M)]`

The `BINARY` type is similar to the `CHAR` type, but stores binary byte strings rather than nonbinary character strings. An optional length `M` represents the column length in bytes. If omitted, `M` defaults to 1.

- `VARBINARY (M)`

The `VARBINARY` type is similar to the `VARCHAR` type, but stores binary byte strings rather than nonbinary character strings. `M` represents the maximum column length in bytes.

- `TINYBLOB`

A `BLOB` column with a maximum length of 255 ($2^8 - 1$) bytes. Each `TINYBLOB` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 255 ($2^8 - 1$) characters. The effective maximum length is less if the value contains multibyte characters. Each `TINYTEXT` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `BLOB [(M)]`

A `BLOB` column with a maximum length of 65,535 ($2^{16} - 1$) bytes. Each `BLOB` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length `M` can be given for this type. If this is done, MySQL creates the column as the smallest `BLOB` type large enough to hold values `M` bytes long.

- `TEXT [(M)] [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 65,535 ($2^{16} - 1$) characters. The effective maximum length is less if the value contains multibyte characters. Each `TEXT` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length `M` can be given for this type. If this is done, MySQL creates the column as the smallest `TEXT` type large enough to hold values `M` characters long.

- `MEDIUMBLOB`

A `BLOB` column with a maximum length of 16,777,215 ($2^{24} - 1$) bytes. Each `MEDIUMBLOB` value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- `MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 16,777,215 ($2^{24} - 1$) characters. The effective maximum length is less if the value contains multibyte characters. Each `MEDIUMTEXT` value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- `LONGBLOB`

A `BLOB` column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) bytes. The effective maximum length of `LONGBLOB` columns depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGBLOB` value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- `LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) characters. The effective maximum length is less if the value contains multibyte characters. The effective maximum length of `LONGTEXT` columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGTEXT` value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- `ENUM('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]`

An enumeration. A string object that can have only one value, chosen from the list of values `'value1', 'value2', ..., NULL` or the special `' '` error value. `ENUM` values are represented internally as integers.

An `ENUM` column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on these limits, see [Limits Imposed by .frm File Structure](#).

- `SET('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]`

A set. A string object that can have zero or more values, each of which must be chosen from the list of values `'value1', 'value2', ...`. `SET` values are represented internally as integers.

A `SET` column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on this limit, see [Limits Imposed by .frm File Structure](#).

11.3.2 The CHAR and VARCHAR Types

The `CHAR` and `VARCHAR` types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The `CHAR` and `VARCHAR` types are declared with a length that indicates the maximum number of characters you want to store. For example, `CHAR(30)` can hold up to 30 characters.

The length of a `CHAR` column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When `CHAR` values are stored, they are right-padded with spaces to the specified length. When `CHAR` values are retrieved, trailing spaces are removed unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

Values in `VARCHAR` columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See [Section 8.4.7, "Limits on Table Column Count and Row Size"](#).

In contrast to `CHAR`, `VARCHAR` values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a `CHAR` or `VARCHAR` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of non-space characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.10, "Server SQL Modes"](#).

For `VARCHAR` columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For `CHAR` columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

`VARCHAR` values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between `CHAR` and `VARCHAR` by showing the result of storing various string values into `CHAR(4)` and `VARCHAR(4)` columns (assuming that the column uses a single-byte character set such as `latin1`).

| Value | CHAR(4) | Storage Required | VARCHAR(4) | Storage Required |
|------------|---------|------------------|------------|------------------|
| ' ' | ' ' | 4 bytes | ' ' | 1 byte |
| 'ab' | 'ab ' | 4 bytes | 'ab' | 3 bytes |
| 'abcd' | 'abcd' | 4 bytes | 'abcd' | 5 bytes |
| 'abcdefgh' | 'abcd' | 4 bytes | 'abcd' | 5 bytes |

The values shown as stored in the last row of the table apply *only when not using strict mode*; if MySQL is running in strict mode, values that exceed the column length are *not stored*, and an error results.

`InnoDB` encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

If a given value is stored into the `CHAR(4)` and `VARCHAR(4)` columns, the values retrieved from the columns are not always the same because trailing spaces are removed from `CHAR` columns upon retrieval. The following example illustrates this difference:

```
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab  ', 'ab  ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT CONCAT('(', v, ')'), CONCAT('(', c, ')') FROM vc;
+-----+-----+
| CONCAT('(', v, ')') | CONCAT('(', c, ')') |
+-----+-----+
| (ab  )              | (ab)                 |
+-----+-----+
1 row in set (0.06 sec)
```

Values in `CHAR` and `VARCHAR` columns are sorted and compared according to the character set collation assigned to the column.

All MySQL collations are of type PAD SPACE. This means that all `CHAR`, `VARCHAR`, and `TEXT` values are compared without regard to any trailing spaces. “Comparison” in this context does not include the `LIKE` pattern-matching operator, for which trailing spaces are significant. For example:

```
mysql> CREATE TABLE names (myname CHAR(10));
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO names VALUES ('Jones');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT myname = 'Jones', myname = 'Jones  ' FROM names;
+-----+-----+
| myname = 'Jones' | myname = 'Jones  ' |
+-----+-----+
| 1                | 1                  |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT myname LIKE 'Jones', myname LIKE 'Jones  ' FROM names;
+-----+-----+
| myname LIKE 'Jones' | myname LIKE 'Jones  ' |
+-----+-----+
```

```
|          1 |          0 |
+-----+-----+
1 row in set (0.00 sec)
```

This is true for all MySQL versions, and is not affected by the server SQL mode.

Note

For more information about MySQL character sets and collations, see [Chapter 10, Character Sets, Collations, Unicode](#). For additional information about storage requirements, see [Section 11.6, “Data Type Storage Requirements”](#).

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

11.3.3 The BINARY and VARBINARY Types

The `BINARY` and `VARBINARY` types are similar to `CHAR` and `VARCHAR`, except that they store binary strings rather than nonbinary strings. That is, they store byte strings rather than character strings. This means they have the `binary` character set and collation, and comparison and sorting are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for `BINARY` and `VARBINARY` as it is for `CHAR` and `VARCHAR`, except that the length for `BINARY` and `VARBINARY` is measured in bytes rather than characters.

The `BINARY` and `VARBINARY` data types are distinct from the `CHAR BINARY` and `VARCHAR BINARY` data types. For the latter types, the `BINARY` attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary (`_bin`) collation for the column character set (or the table default character set if no column character set is specified) to be used, and the column itself stores nonbinary character strings rather than binary byte strings. For example, if the default character set is `latin1`, `CHAR(5) BINARY` is treated as `CHAR(5) CHARACTER SET latin1 COLLATE latin1_bin`. This differs from `BINARY(5)`, which stores 5-byte binary strings that have the `binary` character set and collation. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 10.8.5, “The binary Collation Compared to _bin Collations”](#).

If strict SQL mode is not enabled and you assign a value to a `BINARY` or `VARBINARY` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For cases of truncation, to cause an error to occur (rather than a warning) and suppress insertion of the value, use strict SQL mode. See [Section 5.1.10, “Server SQL Modes”](#).

When `BINARY` values are stored, they are right-padded with the pad value to the specified length. The pad value is `0x00` (the zero byte). Values are right-padded with `0x00` for inserts, and no trailing bytes are removed for retrievals. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` and space differ in comparisons, with `0x00` sorting before space.

Example: For a `BINARY(3)` column, 'a ' becomes 'a \0' when inserted. 'a\0' becomes 'a \0\0' when inserted. Both inserted values remain unchanged for retrievals.

For `VARBINARY`, there is no padding for inserts and no bytes are stripped for retrievals. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` and space differ in comparisons, with `0x00` sorting before space.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting values into the column that differ only in number of trailing pad bytes results in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a \0' causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the `BINARY` data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how `0x00`-padding of `BINARY` values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+-----+-----+-----+
| HEX(c) | c = 'a' | c = 'a\0\0' |
+-----+-----+-----+
| 610000 | 0       | 1           |
+-----+-----+-----+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use `VARBINARY` or one of the `BLOB` data types instead.

11.3.4 The BLOB and TEXT Types

A `BLOB` is a binary large object that can hold a variable amount of data. The four `BLOB` types are `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`. These differ only in the maximum length of the values they can hold. The four `TEXT` types are `TINYTEXT`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`. These correspond to the four `BLOB` types and have the same maximum lengths and storage requirements. See [Section 11.6, “Data Type Storage Requirements”](#).

`BLOB` values are treated as binary strings (byte strings). They have the `binary` character set and collation, and comparison and sorting are based on the numeric values of the bytes in column values. `TEXT` values are treated as nonbinary strings (character strings). They have a character set other than `binary`, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a `BLOB` or `TEXT` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.10, “Server SQL Modes”](#).

Truncation of excess trailing spaces from values to be inserted into `TEXT` columns always generates a warning, regardless of the SQL mode.

For `TEXT` and `BLOB` columns, there is no padding on insert and no bytes are stripped on select.

If a `TEXT` column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors will occur for values that differ only in the number of trailing spaces. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error. This is not true for `BLOB` columns.

In most respects, you can regard a `BLOB` column as a `VARBINARY` column that can be as large as you like. Similarly, you can regard a `TEXT` column as a `VARCHAR` column. `BLOB` and `TEXT` differ from `VARBINARY` and `VARCHAR` in the following ways:

- For indexes on `BLOB` and `TEXT` columns, you must specify an index prefix length. For `CHAR` and `VARCHAR`, a prefix length is optional. See [Section 8.3.4, “Column Indexes”](#).
- `BLOB` and `TEXT` columns cannot have `DEFAULT` values.

If you use the `BINARY` attribute with a `TEXT` data type, the column is assigned the binary (`_bin`) collation of the column character set.

`LONG` and `LONG VARCHAR` map to the `MEDIUMTEXT` data type. This is a compatibility feature.

MySQL Connector/ODBC defines `BLOB` values as `LONGVARBINARY` and `TEXT` values as `LONGVARCHAR`.

Because `BLOB` and `TEXT` values can be extremely long, you might encounter some constraints in using them:

- Only the first `max_sort_length` bytes of the column are used when sorting. The default value of `max_sort_length` is 1024. You can make more bytes significant in sorting or grouping by increasing the value of `max_sort_length` at server startup or runtime. Any client can change the value of its session `max_sort_length` variable:

```
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
-> ORDER BY comment;
```

- Instances of `BLOB` or `TEXT` columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the `MEMORY` storage engine does not support those data types (see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#)). Use of disk incurs a performance penalty, so include `BLOB` or `TEXT` columns in the query result only if they are really needed. For example, avoid using `SELECT *`, which selects all columns.
- The maximum size of a `BLOB` or `TEXT` object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the `max_allowed_packet` variable, but you must do so for both the server and your client program. For example, both `mysql` and `mysqldump` enable you to change the client-side `max_allowed_packet` value. See [Section 5.1.1, “Configuring the Server”](#), [Section 4.5.1, “mysql — The MySQL Command-Line Client”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see [Section 11.6, “Data Type Storage Requirements”](#)

Each `BLOB` or `TEXT` value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in `BLOB` or `TEXT` columns. You may find MySQL's string handling functions useful for working with such data. See [Section 12.7, “String Functions and Operators”](#). For security and other reasons, it is usually preferable to do so using application code rather than giving application users the `FILE` privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (<http://forums.mysql.com/>).

11.3.5 The ENUM Type

An `ENUM` is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time. It has these advantages:

- Compact data storage in situations where a column has a limited set of possible values. The strings you specify as input values are automatically encoded as numbers. See [Section 11.6, “Data Type Storage Requirements”](#) for the storage requirements for `ENUM` types.
- Readable queries and output. The numbers are translated back to the corresponding strings in query results.

and these potential issues to consider:

- If you make enumeration values that look like numbers, it is easy to mix up the literal values with their internal index numbers, as explained in [Enumeration Limitations](#).
- Using `ENUM` columns in `ORDER BY` clauses requires extra care, as explained in [Enumeration Sorting](#).
- [Creating and Using ENUM Columns](#)
- [Index Values for Enumeration Literals](#)

- [Handling of Enumeration Literals](#)
- [Empty or NULL Enumeration Values](#)
- [Enumeration Sorting](#)
- [Enumeration Limitations](#)

Creating and Using ENUM Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an `ENUM` column like this:

```
CREATE TABLE shirts (
  name VARCHAR(40),
  size ENUM('x-small', 'small', 'medium', 'large', 'x-large')
);
INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'),
 ('polo shirt','small');
SELECT name, size FROM shirts WHERE size = 'medium';
+-----+-----+
| name   | size  |
+-----+-----+
| t-shirt | medium |
+-----+-----+
UPDATE shirts SET size = 'small' WHERE size = 'large';
COMMIT;
```

Inserting 1 million rows into this table with a value of `'medium'` would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string `'medium'` in a `VARCHAR` column.

Index Values for Enumeration Literals

Each enumeration value has an index:

- The elements listed in the column specification are assigned index numbers, beginning with 1.
- The index value of the empty string error value is 0. This means that you can use the following `SELECT` statement to find rows into which invalid `ENUM` values were assigned:

```
mysql> SELECT * FROM tbl_name WHERE enum_col=0;
```

- The index of the `NULL` value is `NULL`.
- The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as `ENUM('Mercury', 'Venus', 'Earth')` can have any of the values shown here. The index of each value is also shown.

| Value | Index |
|------------------------|-------------------|
| <code>NULL</code> | <code>NULL</code> |
| <code>'</code> | 0 |
| <code>'Mercury'</code> | 1 |
| <code>'Venus'</code> | 2 |
| <code>'Earth'</code> | 3 |

An `ENUM` column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on these limits, see [Limits Imposed by .frm File Structure](#).

If you retrieve an `ENUM` value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an `ENUM` column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `ENUM` values, the index number is used in the calculation.

Handling of Enumeration Literals

Trailing spaces are automatically deleted from `ENUM` member values in the table definition when a table is created.

When retrieved, values stored into an `ENUM` column are displayed using the lettercase that was used in the column definition. Note that `ENUM` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an `ENUM` column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does *not* work with `LOAD DATA`, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an `ENUM` column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of '0', '1', and '2', but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes '1' (the value with index 2). If you store '2', it matches an enumeration value, so it is stored as '2'. If you store '3', it does not match any enumeration value, so it is treated as an index and becomes '2' (the value with index 3).

```
mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
mysql> SELECT * FROM t;
+-----+
| numbers |
+-----+
| 1       |
| 2       |
| 2       |
+-----+
```

To determine all possible values for an `ENUM` column, use `SHOW COLUMNS FROM tbl_name LIKE 'enum_col'` and parse the `ENUM` definition in the `Type` column of the output.

In the C API, `ENUM` values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [Section 23.7.4, "C API Data Structures"](#).

Empty or NULL Enumeration Values

An enumeration value can also be the empty string ('') or `NULL` under certain circumstances:

- If you insert an invalid value into an `ENUM` (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a "normal" empty string by the fact that this string has the numeric value 0. See [Index Values for Enumeration Literals](#) for details about the numeric indexes for the enumeration values.

If strict SQL mode is enabled, attempts to insert invalid `ENUM` values result in an error.

- If an `ENUM` column is declared to permit `NULL`, the `NULL` value is a valid value for the column, and the default value is `NULL`. If an `ENUM` column is declared `NOT NULL`, its default value is the first element of the list of permitted values.

Enumeration Sorting

`ENUM` values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, 'b' sorts before 'a' for `ENUM('b', 'a')`. The empty string sorts before nonempty strings, and `NULL` values sort before all other enumeration values.

To prevent unexpected results when using the `ORDER BY` clause on an `ENUM` column, use one of these techniques:

- Specify the `ENUM` list in alphabetic order.
- Make sure that the column is sorted lexically rather than by index number by coding `ORDER BY CAST(col AS CHAR)` or `ORDER BY CONCAT(col)`.

Enumeration Limitations

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this `CREATE TABLE` statement does *not* work because the `CONCAT` function cannot be used to construct an enumeration value:

```
CREATE TABLE sizes (
  size ENUM('small', CONCAT('med','ium'), 'large')
);
```

You also cannot employ a user variable as an enumeration value. This pair of statements do *not* work:

```
SET @mysize = 'medium';
CREATE TABLE sizes (
  size ENUM('small', @mysize, 'large')
);
```

We strongly recommend that you do *not* use numbers as enumeration values, because it does not save on storage over the appropriate `TINYINT` or `SMALLINT` type, and it is easy to mix up the strings and the underlying number values (which might not be the same) if you quote the `ENUM` values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See [Handling of Enumeration Literals](#) to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

11.3.6 The SET Type

A `SET` is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. `SET` column values that consist of multiple set members are specified with members separated by commas (,). A consequence of this is that `SET` member values should not themselves contain commas.

For example, a column specified as `SET('one', 'two') NOT NULL` can have any of these values:

```
' '
'one'
'two'
'one,two'
```

A `SET` column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on this limit, see [Limits Imposed by .frm File Structure](#).

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from SET member values in the table definition when a table is created.

When retrieved, values stored in a SET column are displayed using the lettercase that was used in the column definition. Note that SET columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores SET values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a SET value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a SET column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a SET column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as SET('a', 'b', 'c', 'd'), the members have the following decimal and binary values.

| SET Member | Decimal Value | Binary Value |
|------------|---------------|--------------|
| 'a' | 1 | 0001 |
| 'b' | 2 | 0010 |
| 'c' | 4 | 0100 |
| 'd' | 8 | 1000 |

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth SET value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one SET element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. Suppose that a column is specified as SET('a', 'b', 'c', 'd'):

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES
-> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

Then all these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
+-----+
| col   |
+-----+
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
+-----+
5 rows in set (0.04 sec)
```

If you set a SET column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
```

```

| Level | Code | Message |
+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+-----+-----+-----+
1 row in set (0.04 sec)

mysql> SELECT col FROM myset;
+-----+
| col |
+-----+
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
+-----+
6 rows in set (0.01 sec)

```

If strict SQL mode is enabled, attempts to insert invalid `SET` values result in an error.

`SET` values are sorted numerically. `NULL` values sort before non-`NULL` `SET` values.

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` values, the cast operation causes the numeric value to be used.

Normally, you search for `SET` values using the `FIND_IN_SET()` function or the `LIKE` operator:

```

mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value',set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';

```

The first statement finds rows where `set_col` contains the `value` set member. The second is similar, but not the same: It finds rows where `set_col` contains `value` anywhere, even as a substring of another set member.

The following statements also are permitted:

```

mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';

```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to `'val1,val2'` returns different results than comparing values to `'val2,val1'`. You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a `SET` column, use `SHOW COLUMNS FROM tbl_name LIKE set_col` and parse the `SET` definition in the `Type` column of the output.

In the C API, `SET` values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [Section 23.7.4, “C API Data Structures”](#).

11.4 Spatial Data Types

The [Open Geospatial Consortium](#) (OGC) is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data.

The Open Geospatial Consortium publishes the *OpenGIS® Implementation Standard for Geographic information - Simple Feature Access - Part 2: SQL Option*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC website at <http://www.opengeospatial.org/standards/sfs>.

Following the OGC specification, MySQL implements spatial extensions as a subset of the **SQL with Geometry Types** environment. This term refers to an SQL environment that has been extended

with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

MySQL spatial extensions enable the generation, storage, and analysis of geographic features:

- Data types for representing spatial values
- Functions for manipulating spatial values
- Spatial indexing for improved access times to spatial columns

The spatial data types and functions are available for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables. For indexing spatial columns, [MyISAM](#) supports both [SPATIAL](#) and non-[SPATIAL](#) indexes. The other storage engines support non-[SPATIAL](#) indexes, as described in [Section 13.1.13, “CREATE INDEX Statement”](#).

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

The discussion here considers these terms synonymous: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. The term most commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

The following material covers these topics:

- The spatial data types implemented in MySQL model
- The basis of the spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

For information about functions that operate on spatial data, see [Section 12.16, “Spatial Analysis Functions”](#).

MySQL GIS Conformance and Compatibility

MySQL does not implement the following GIS features:

- Additional Metadata Views

OpenGIS specifications propose several additional metadata views. For example, a system view named [GEOMETRY_COLUMNS](#) contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` on `LineString` and `MultiLineString` should be called in MySQL as `GLength()`

The problem is that there is an existing SQL function `Length()` that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context.

Additional Resources

The Open Geospatial Consortium publishes the *OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. The Open Geospatial Consortium (OGC) maintains a website at <http://www.opengeospatial.org/>. The specification is available there at <http://www.opengeospatial.org/standards/sfs>. It contains additional information relevant to the material here.

If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <https://forums.mysql.com/list.php?23>.

11.4.1 Spatial Data Types

MySQL has spatial data types that correspond to OpenGIS classes. The basis for these types is described in [Section 11.4.2, “The OpenGIS Geometry Model”](#).

Some spatial data types hold single geometry values:

- `GEOMETRY`
- `POINT`
- `LINestring`
- `POLYGON`

`GEOMETRY` can store geometry values of any type. The other single-value types (`POINT`, `LINestring`, and `POLYGON`) restrict their values to a particular geometry type.

The other spatial data types hold collections of values:

- `MULTIPOINT`
- `MULTILINestring`
- `MULTIPOLYGON`
- `GEOMETRYCOLLECTION`

`GEOMETRYCOLLECTION` can store a collection of objects of any type. The other collection types (`MULTIPOINT`, `MULTILINestring`, and `MULTIPOLYGON`) restrict collection members to those having a particular geometry type.

Example: To create a table named `geom` that has a column named `g` that can store values of any geometry type, use this statement:

```
CREATE TABLE geom (g GEOMETRY);
```

`SPATIAL` indexes can be created on `NOT NULL` spatial columns, so if you plan to index the column, declare it `NOT NULL`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL);
```

For other examples showing how to use spatial data types in MySQL, see [Section 11.4.4, “Creating Spatial Columns”](#).

11.4.2 The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a spatial reference system, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

11.4.2.1 The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- `Geometry` (noninstantiable)
 - `Point` (instantiable)
 - `Curve` (noninstantiable)
 - `LineString` (instantiable)
 - `Line`
 - `LinearRing`
 - `Surface` (noninstantiable)
 - `Polygon` (instantiable)
 - `GeometryCollection` (instantiable)
 - `MultiPoint` (instantiable)
 - `MultiCurve` (noninstantiable)
 - `MultiLineString` (instantiable)
 - `MultiSurface` (noninstantiable)
 - `MultiPolygon` (instantiable)

It is not possible to create objects in noninstantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It is an abstract class. The instantiable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with sub-subclasses `Line` and `LinearRing`.
- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding

to collections of [Points](#), [LineStrings](#), and [Polygons](#), respectively. [MultiCurve](#) and [MultiSurface](#) are introduced as abstract superclasses that generalize the collection interfaces to handle [Curves](#) and [Surfaces](#).

[Geometry](#), [Curve](#), [Surface](#), [MultiCurve](#), and [MultiSurface](#) are defined as noninstantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

[Point](#), [LineString](#), [Polygon](#), [GeometryCollection](#), [MultiPoint](#), [MultiLineString](#), and [MultiPolygon](#) are instantiable classes.

11.4.2.2 Geometry Class

[Geometry](#) is the root class of the hierarchy. It is a noninstantiable class but has a number of properties, described in the following list, that are common to all geometry values created from any of the [Geometry](#) subclasses. Particular subclasses have their own specific properties, described later.

Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or spatial reference identifier. This value identifies the geometry's associated spatial reference system that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32}-1$. If a larger value is given, only the lower 32 bits are used. All computations are done assuming SRID 0, regardless of the actual SRID value. SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes.

- Its **coordinates** in its spatial reference system, represented as double-precision (8-byte) numbers. All nonempty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geodetic** system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (minimum bounding rectangle), or envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **nonsimple**. Geometry values of types ([LineString](#), [MultiPoint](#), [MultiLineString](#)) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.
- Whether the value is **closed** or **not closed**. Geometry values of types ([LineString](#), [MultiString](#)) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **nonempty**. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a [NULL](#) value). An empty geometry is defined to be always simple and has an area of 0.

- Its **dimension**. A geometry can have a dimension of -1 , 0 , 1 , or 2 :
 - -1 for an empty geometry.
 - 0 for a geometry with no length and no area.
 - 1 for a geometry with nonzero length and zero area.
 - 2 for a geometry with nonzero area.

`Point` objects have a dimension of zero. `LineString` objects have a dimension of 1. `Polygon` objects have a dimension of 2. The dimensions of `MultiPoint`, `MultiLineString`, and `MultiPolygon` objects are the same as the dimensions of the elements they consist of.

11.4.2.3 Point Class

A `Point` is a geometry that represents a single location in coordinate space.

`Point` Examples

- Imagine a large-scale map of the world with many cities. A `Point` object could represent each city.
- On a city map, a `Point` object could represent a bus stop.

`Point` Properties

- X-coordinate value.
- Y-coordinate value.
- `Point` is defined as a zero-dimensional geometry.
- The boundary of a `Point` is the empty set.

11.4.2.4 Curve Class

A `Curve` is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of `Curve` define the type of interpolation between points. `Curve` is a noninstantiable class.

`Curve` Properties

- A `Curve` has the coordinates of its points.
- A `Curve` is defined as a one-dimensional geometry.
- A `Curve` is simple if it does not pass through the same point twice, with the exception that a curve can still be simple if the start and end points are the same.
- A `Curve` is closed if its start point is equal to its endpoint.
- The boundary of a closed `Curve` is empty.
- The boundary of a nonclosed `Curve` consists of its two endpoints.
- A `Curve` that is simple and closed is a `LinearRing`.

11.4.2.5 LineString Class

A `LineString` is a `Curve` with linear interpolation between points.

`LineString` Examples

- On a world map, `LineString` objects could represent rivers.

- In a city map, `LineString` objects could represent streets.

LineString Properties

- A `LineString` has coordinates of segments, defined by each consecutive pair of points.
- A `LineString` is a `Line` if it consists of exactly two points.
- A `LineString` is a `LinearRing` if it is both closed and simple.

11.4.2.6 Surface Class

A `Surface` is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is `Polygon`.

Surface Properties

- A `Surface` is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple `Surface` as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple `Surface` is the set of closed curves corresponding to its exterior and interior boundaries.

11.4.2.7 Polygon Class

A `Polygon` is a planar `Surface` representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the `Polygon`.

Polygon Examples

- On a region map, `Polygon` objects could represent forests, districts, and so on.

Polygon Assertions

- The boundary of a `Polygon` consists of a set of `LinearRing` objects (that is, `LineString` objects that are both simple and closed) that make up its exterior and interior boundaries.
- A `Polygon` has no rings that cross. The rings in the boundary of a `Polygon` may intersect at a `Point`, but only as a tangent.
- A `Polygon` has no lines, spikes, or punctures.
- A `Polygon` has an interior that is a connected point set.
- A `Polygon` may have holes. The exterior of a `Polygon` with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a `Polygon` a simple geometry.

11.4.2.8 GeometryCollection Class

A `GeometryCollection` is a geometry that is a collection of zero or more geometries of any class.

All the elements in a geometry collection must be in the same spatial reference system (that is, in the same coordinate system). There are no other constraints on the elements of a geometry collection, although the subclasses of `GeometryCollection` described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a `MultiPoint` may contain only `Point` elements)

- Dimension
- Constraints on the degree of spatial overlap between elements

11.4.2.9 MultiPoint Class

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

MultiPoint Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

MultiPoint Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).
- The boundary of a `MultiPoint` is the empty set.

11.4.2.10 MultiCurve Class

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a noninstantiable class.

MultiCurve Properties

- A `MultiCurve` is a one-dimensional geometry.
- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `Curve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

11.4.2.11 MultiLineString Class

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

MultiLineString Examples

- On a region map, a `MultiLineString` could represent a river system or a highway system.

11.4.2.12 MultiSurface Class

A `MultiSurface` is a geometry collection composed of surface elements. `MultiSurface` is a noninstantiable class. Its only instantiable subclass is `MultiPolygon`.

MultiSurface Assertions

- Surfaces within a `MultiSurface` have no interiors that intersect.
- Surfaces within a `MultiSurface` have boundaries that intersect at most at a finite number of points.

11.4.2.13 MultiPolygon Class

A `MultiPolygon` is a `MultiSurface` object composed of `Polygon` elements.

MultiPolygon Examples

- On a region map, a `MultiPolygon` could represent a system of lakes.

MultiPolygon Assertions

- A `MultiPolygon` has no two `Polygon` elements with interiors that intersect.
- A `MultiPolygon` has no two `Polygon` elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of `Polygon` values in the `MultiPolygon`.

MultiPolygon Properties

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.
- Each `Curve` in the boundary of the `MultiPolygon` is in the boundary of exactly one `Polygon` element.
- Every `Curve` in the boundary of an `Polygon` element is in the boundary of the `MultiPolygon`.

11.4.3 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format. (Internal format is like WKB but with an initial 4 bytes to indicate the SRID.)

There are functions available to convert between different data formats; see [Section 12.16.6, “Geometry Format Conversion Functions”](#).

The following sections describe the spatial data formats MySQL uses:

- [Well-Known Text \(WKT\) Format](#)
- [Well-Known Binary \(WKB\) Format](#)
- [Internal Geometry Storage Format](#)

Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see [Section 11.4, “Spatial Data Types”](#)).

Examples of WKT representations of geometry objects:

- A `Point`:

```
POINT(15 20)
```

The point coordinates are specified with no separating comma. This differs from the syntax for the SQL `Point()` function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both use `X()` to extract the X-coordinate from a `Point` object. The first produces the object directly using the `Point()` function. The second uses a WKT representation converted to a `Point` with `GeomFromText()`.

```
mysql> SELECT X(Point(15, 20));
+-----+
| X(Point(15, 20)) |
+-----+
|                15 |
+-----+

mysql> SELECT X(GeomFromText('POINT(15 20)'));
+-----+
| X(GeomFromText('POINT(15 20)')) |
+-----+
|                15 |
+-----+
```

- A `LineString` with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

The point coordinate pairs are separated by commas.

- A `Polygon` with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A `MultiPoint` with three `Point` values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

- A `MultiLineString` with two `LineString` values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A `MultiPolygon` with two `Polygon` values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A `GeometryCollection` consisting of two `Point` values and one `LineString`:

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
```

Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by `BLOB` values containing geometric WKB information. This format is defined by the OpenGIS specification (see [Section 11.4, "Spatial Data Types"](#)). It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 -1)` consists of this sequence of 21 bytes, each represented by two hexadecimal digits:

```
010100000000000000000000F03F000000000000F0BF
```

The sequence consists of the components shown in the following table.

Table 11.2 WKB Components Example

| Component | Size | Value |
|--------------|---------|------------------|
| Byte order | 1 byte | 01 |
| WKB type | 4 bytes | 01000000 |
| X coordinate | 8 bytes | 000000000000F03F |
| Y coordinate | 8 bytes | 000000000000F0BF |

Component representation is as follows:

- The byte order indicator is either 1 or 0 to signify little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. MySQL uses values from 1 through 7 to indicate [Point](#), [LineString](#), [Polygon](#), [MultiPoint](#), [MultiLineString](#), [MultiPolygon](#), and [GeometryCollection](#).
- A [Point](#) value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

Internal Geometry Storage Format

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. For a description of WKB format, see [Well-Known Binary \(WKB\) Format](#).

For the WKB part, these MySQL-specific considerations apply:

- The byte-order indicator byte is 1 because MySQL stores geometries as little-ending values.
- MySQL supports geometry types of [Point](#), [LineString](#), [Polygon](#), [MultiPoint](#), [MultiLineString](#), [MultiPolygon](#), and [GeometryCollection](#). Other geometry types are not supported.

The `LENGTH()` function returns the space in bytes required for value storage. Example:

```
mysql> SET @g = GeomFromText('POINT(1 -1)');
mysql> SELECT LENGTH(@g);
+-----+
| LENGTH(@g) |
+-----+
|          25 |
+-----+
mysql> SELECT HEX(@g);
+-----+
| HEX(@g) |
+-----+
| 00000000010100000000000000000000F03F000000000000F0BF |
+-----+
```

The value length is 25 bytes, made up of these components (as can be seen from the hexadecimal value):

- 4 bytes for integer SRID (0)
- 1 byte for integer byte order (1 = little-endian)

- 4 bytes for integer type information (1 = `Point`)
- 8 bytes for double-precision X coordinate (1)
- 8 bytes for double-precision Y coordinate (-1)

11.4.4 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Spatial columns are supported for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables. See also the notes about spatial indexes under [Section 11.4.8, “Creating Spatial Indexes”](#).

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

11.4.5 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:

- Perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (GeomFromText(@g));
```

- Perform the conversion prior to the `INSERT`:

```
SET @g = GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples use `GeomFromText()` to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (PolygonFromText(@g));
```

```
SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

```
INSERT INTO geom VALUES
(GeomFromWKB(X'010100000000000000000000F03F000000000000F03F'));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```
INSERT INTO geom VALUES (GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See [Section 23.7.6.53](#), “`mysql_real_escape_string()`”.

11.4.6 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `AsText()` function converts a geometry from internal format to a WKT string.

```
SELECT AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `AsBinary()` function converts a geometry from internal format to a `BLOB` containing the WKB value.

```
SELECT AsBinary(g) FROM geom;
```

11.4.7 Optimizing Spatial Analysis

For `MyISAM` tables, search operations in columns containing spatial data can be optimized using `SPATIAL` indexes. The most typical operations are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

`MyISAM` supports both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 13.1.13, “CREATE INDEX Statement”](#).

11.4.8 Creating Spatial Indexes

For `MyISAM` tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the `SPATIAL` keyword. Columns in spatial indexes must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g)) ENGINE=MyISAM;
```

- With `ALTER TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL) ENGINE=MyISAM;
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL) ENGINE=MyISAM;
CREATE SPATIAL INDEX g ON geom (g);
```

`SPATIAL INDEX` creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see [Section 13.1.13, “CREATE INDEX Statement”](#).

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
DROP INDEX g ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra           |
+-----+-----+-----+-----+-----+-----+
| fid   | int(11)|      | PRI | NULL    | auto_increment |
| g     | geometry|     |     |         |                 |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
| 32376    |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g) ENGINE=MyISAM;
Query OK, 32376 rows affected (4.05 sec)
```

Records: 32376 Duplicates: 0 Warnings: 0

11.4.9 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g);
```

| fid | AsText(g) |
|-----|---|
| 21 | LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 |
| 22 | LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ... |
| 23 | LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ... |
| 24 | LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ... |
| 25 | LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ... |
| 26 | LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ... |
| 249 | LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ... |
| 1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ... |
| 2 | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136, ... |
| 3 | LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ... |
| 4 | LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ... |
| 5 | LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ... |
| 6 | LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ... |
| 7 | LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ... |
| 10 | LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ... |
| 11 | LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ... |
| 13 | LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ... |
| 154 | LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ... |
| 155 | LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ... |
| 157 | LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ... |

20 rows in set (0.00 sec)

Use `EXPLAIN` to check the way this query is executed:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: range
possible_keys: g
          key: g
         key_len: 32
          ref: NULL
         rows: 50
       Extra: Using where
1 row in set (0.00 sec)
```

Check what would happen without a spatial index:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
```

```

          31000 16000,
          30000 16000,
          30000 15000));
mysql> EXPLAIN SELECT fid,AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: ALL

11.5 Data Type Default Values

Data type specifications can have explicit or implicit default values.

- [Handling of Explicit Defaults](#)
- [Handling of Implicit Defaults](#)

Handling of Explicit Defaults

A `DEFAULT value` clause in a data type specification explicitly indicates a default value for a column. Examples:

```
CREATE TABLE t1 (
```

```
i      INT DEFAULT -1,
c      VARCHAR(10) DEFAULT '',
price DOUBLE(16,2) DEFAULT '0.00'
);
```

[SERIAL DEFAULT VALUE](#) is a special case. In the definition of an integer column, it is an alias for [NOT NULL AUTO_INCREMENT UNIQUE](#).

With one exception, the default value specified in a [DEFAULT](#) clause must be a literal constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as [NOW\(\)](#) or [CURRENT_DATE](#). The exception is that, for a [TIMESTAMP](#) column, you can specify [CURRENT_TIMESTAMP](#) as the default. See [Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP”](#).

The [BLOB](#) and [TEXT](#) data types cannot be assigned a default value.

Handling of Implicit Defaults

If a data type specification includes no explicit [DEFAULT](#) value, MySQL determines the default value as follows:

If the column can take [NULL](#) as a value, the column is defined with an explicit [DEFAULT NULL](#) clause.

If the column cannot take [NULL](#) as a value, MySQL defines the column with no explicit [DEFAULT](#) clause. Exception: If the column is defined as part of a [PRIMARY KEY](#) but not explicitly as [NOT NULL](#), MySQL creates it as a [NOT NULL](#) column (because [PRIMARY KEY](#) columns must be [NOT NULL](#)), but also assigns it a [DEFAULT](#) clause using the implicit default value. To prevent this, include an explicit [NOT NULL](#) in the definition of any [PRIMARY KEY](#) column.

For data entry into a [NOT NULL](#) column that has no explicit [DEFAULT](#) clause, if an [INSERT](#) or [REPLACE](#) statement includes no value for the column, or an [UPDATE](#) statement sets the column to [NULL](#), MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.
- If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table `t` is defined as follows:

```
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because [DEFAULT\(i\)](#) cannot produce a value:

```
INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));
```

See [Section 5.1.10, “Server SQL Modes”](#).

For a given table, the [SHOW CREATE TABLE](#) statement displays which columns have an explicit [DEFAULT](#) clause.

Implicit defaults are defined as follows:

- For numeric types, the default is `0`, with the exception that for integer or floating-point types declared with the [AUTO_INCREMENT](#) attribute, the default is the next value in the sequence.

- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. For the first `TIMESTAMP` column in a table, the default value is the current date and time. See [Section 11.2, “Date and Time Data Types”](#).
- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

11.6 Data Type Storage Requirements

- [InnoDB Table Storage Requirements](#)
- [NDBCLUSTER Table Storage Requirements](#)
- [Numeric Type Storage Requirements](#)
- [Date and Time Type Storage Requirements](#)
- [String Type Storage Requirements](#)
- [Spatial Type Storage Requirements](#)

The storage requirements for data vary, according to the storage engine being used for the table in question. Different storage engines use different methods for recording the raw data and different data types. In addition, some engines may compress the information in a given row, either on a column or entire row basis, making calculation of the storage requirements for a given table or column structure.

However, all storage engines must communicate and exchange information on a given row within a table using the same structure, and this information is consistent, irrespective of the storage engine used to write the information to disk.

This sections includes some guidelines and information for the storage requirements for each data type supported by MySQL, including details for the internal format and the sizes used by storage engines that used a fixed size representation for different types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes `BLOB` or `TEXT` columns, which contribute only 9 to 12 bytes toward this size. For `BLOB` and `TEXT` data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more information, see [Chapter 15, *Alternative Storage Engines*](#), and [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

InnoDB Table Storage Requirements

See [Section 14.14, “InnoDB Row Formats”](#) for information about storage requirements for `InnoDB` tables.

NDBCLUSTER Table Storage Requirements

Important

For tables using the `NDBCLUSTER` storage engine, there is the factor of *4-byte alignment* to be taken into account when calculating storage requirements. This means that all `NDB` data storage is done in multiples of 4 bytes. Thus, a column value that would take 15 bytes in a table using a storage engine other than `NDB` requires 16 bytes in an `NDB` table. This requirement applies in addition to any other considerations that are discussed in this section. For example, in `NDBCLUSTER` tables, the `TINYINT`, `SMALLINT`, `MEDIUMINT`, and

INTEGER (INT) column types each require 4 bytes storage per record due to the alignment factor.

An exception to this rule is the **BIT** type, which is *not* 4-byte aligned. In NDB Cluster tables, a **BIT(M)** column takes *M* bits of storage space. However, if a table definition contains 1 or more **BIT** columns (up to 32 **BIT** columns), then **NDBCLUSTER** reserves 4 bytes (32 bits) per row for these. If a table definition contains more than 32 **BIT** columns (up to 64 such columns), then **NDBCLUSTER** reserves 8 bytes (that is, 64 bits) per row.

In addition, while a **NULL** itself does not require any storage space, **NDBCLUSTER** reserves 4 bytes per row if the table definition contains any columns defined as **NULL**, up to 32 **NULL** columns. (If an NDB Cluster table is defined with more than 32 **NULL** columns up to 64 **NULL** columns, then 8 bytes per row is reserved.)

When calculating storage requirements for NDB Cluster tables, you must also remember that every table using the **NDBCLUSTER** storage engine requires a primary key; if no primary key is defined by the user, then a “hidden” primary key will be created by **NDB**. This hidden primary key consumes 31-35 bytes per table record.

You may find the `ndb_size.pl` utility to be useful for estimating **NDB** storage requirements. This Perl script connects to a current MySQL (non-Cluster) database and creates a report on how much space that database would require if it used the **NDBCLUSTER** storage engine. See [Section 18.4.25, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”](#), for more information.

Numeric Type Storage Requirements

| Data Type | Storage Required |
|-----------------------------------|--|
| TINYINT | 1 byte |
| SMALLINT | 2 bytes |
| MEDIUMINT | 3 bytes |
| INT, INTEGER | 4 bytes |
| BIGINT | 8 bytes |
| FLOAT(p) | 4 bytes if $0 \leq p \leq 24$, 8 bytes if $25 \leq p \leq 53$ |
| FLOAT | 4 bytes |
| DOUBLE [PRECISION], REAL | 8 bytes |
| DECIMAL(M,D), NUMERIC(M,D) | Varies; see following discussion |
| BIT(M) | approximately $(M+7)/8$ bytes |

Values for **DECIMAL** (and **NUMERIC**) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

| Leftover Digits | Number of Bytes |
|-----------------|-----------------|
| 0 | 0 |
| 1 | 1 |
| 2 | 1 |
| 3 | 2 |
| 4 | 2 |
| 5 | 3 |

| Leftover Digits | Number of Bytes |
|-----------------|-----------------|
| 6 | 3 |
| 7 | 4 |
| 8 | 4 |

Date and Time Type Storage Requirements

| Data Type | Storage Required |
|------------------------|------------------|
| <code>DATE</code> | 3 bytes |
| <code>TIME</code> | 3 bytes |
| <code>DATETIME</code> | 8 bytes |
| <code>TIMESTAMP</code> | 4 bytes |
| <code>YEAR</code> | 1 byte |

For details about internal representation of temporal values, see [MySQL Internals: Important Algorithms and Structures](#).

String Type Storage Requirements

In the following table, M represents the declared column length in characters for nonbinary string types and bytes for binary string types. L represents the actual length in bytes of a given string value.

| Data Type | Storage Required |
|---|--|
| <code>CHAR(M)</code> | The compact family of InnoDB row formats optimize storage for variable-length character sets. See COMPACT Row Format Storage Characteristics . Otherwise, $M \times w$ bytes, $\leq M \leq 255$, where w is the number of bytes required for the maximum-length character in the character set. |
| <code>BINARY(M)</code> | M bytes, $0 \leq M \leq 255$ |
| <code>VARCHAR(M)</code> , <code>VARBINARY(M)</code> | $L + 1$ bytes if column values require 0 – 255 bytes, $L + 2$ bytes if values may require more than 255 bytes |
| <code>TINYBLOB</code> , <code>TINYTEXT</code> | $L + 1$ bytes, where $L < 2^8$ |
| <code>BLOB</code> , <code>TEXT</code> | $L + 2$ bytes, where $L < 2^{16}$ |
| <code>MEDIUMBLOB</code> , <code>MEDIUMTEXT</code> | $L + 3$ bytes, where $L < 2^{24}$ |
| <code>LONGBLOB</code> , <code>LONGTEXT</code> | $L + 4$ bytes, where $L < 2^{32}$ |
| <code>ENUM('value1', 'value2', ...)</code> | 1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum) |
| <code>SET('value1', 'value2', ...)</code> | 1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum) |

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is L (the byte length of the string). For example, storage for a `MEDIUMTEXT` value requires L bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular `CHAR`, `VARCHAR`, or `TEXT` column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using a `utf8` Unicode character set, you must keep in mind that not all characters use the same number of bytes. `utf8mb3` and `utf8mb4` character sets can require up to three and four bytes per character, respectively. For a breakdown of the storage used for different categories of `utf8mb3` or `utf8mb4` characters, see [Section 10.9, “Unicode Support”](#).

`VARCHAR`, `VARBINARY`, and the `BLOB` and `TEXT` types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a `VARCHAR(255)` column can hold a string with a maximum length of 255 characters. Assuming that the column uses the `latin1` character set (one byte per character), the actual storage required is the length of the string (L), plus one byte to record the length of the string. For the string `'abcd'`, L is 4 and the storage requirement is five bytes. If the same column is instead declared to use the `ucs2` double-byte character set, the storage requirement is 10 bytes: The length of `'abcd'` is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of *bytes* that can be stored in a `VARCHAR` or `VARBINARY` column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a `VARCHAR` column that stores multibyte characters, the effective maximum number of *characters* is less. For example, `utf8mb3` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8mb3` character set can be declared to be a maximum of 21,844 characters. See [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

`InnoDB` encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

The `NDBCLUSTER` storage engine supports variable-width columns. This means that a `VARCHAR` column in an NDB Cluster table requires the same amount of storage as would any other storage engine, with the exception that such values are 4-byte aligned. Thus, the string `'abcd'` stored in a `VARCHAR(50)` column using the `latin1` character set requires 8 bytes (rather than 5 bytes for the same column value in a `MyISAM` table).

`TEXT` and `BLOB` columns are implemented differently in the NDB Cluster storage engine, wherein each row in a `TEXT` column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which is stored in a hidden table. The rows in this second table are always 2000 bytes long. This means that the size of a `TEXT` column is 256 if $size \leq 256$ (where $size$ represents the size of the row); otherwise, the size is $256 + size + (2000 \times (size - 256) \% 2000)$.

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See [Section 11.3.5, “The ENUM Type”](#).

The size of a `SET` object is determined by the number of different set members. If the set size is N , the object occupies $(N+7)/8$ bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See [Section 11.3.6, “The SET Type”](#).

Spatial Type Storage Requirements

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. The `LENGTH()` function returns the space in bytes required for value storage.

For descriptions of WKB and internal storage formats for spatial values, see [Section 11.4.3, “Supported Spatial Data Formats”](#).

11.7 Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, -, *, and /) with `DECIMAL` columns are done with precision of 65 decimal (base 10) digits. See [Section 11.1.1, “Numeric Data Type Syntax”](#).

If accuracy is not too important or if speed is the highest priority, the `DOUBLE` type may be good enough. For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

`PROCEDURE ANALYSE` can be used to obtain suggestions for optimal column data types. For more information, see [Section 8.4.2.4, “Using PROCEDURE ANALYSE”](#).

11.8 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

| Other Vendor Type | MySQL Type |
|-----------------------------------|-------------------------|
| <code>BOOL</code> | <code>TINYINT</code> |
| <code>BOOLEAN</code> | <code>TINYINT</code> |
| <code>CHARACTER VARYING(M)</code> | <code>VARCHAR(M)</code> |
| <code>FIXED</code> | <code>DECIMAL</code> |
| <code>FLOAT4</code> | <code>FLOAT</code> |
| <code>FLOAT8</code> | <code>DOUBLE</code> |
| <code>INT1</code> | <code>TINYINT</code> |
| <code>INT2</code> | <code>SMALLINT</code> |
| <code>INT3</code> | <code>MEDIUMINT</code> |
| <code>INT4</code> | <code>INT</code> |
| <code>INT8</code> | <code>BIGINT</code> |
| <code>LONG VARBINARY</code> | <code>MEDIUMBLOB</code> |
| <code>LONG VARCHAR</code> | <code>MEDIUMTEXT</code> |
| <code>LONG</code> | <code>MEDIUMTEXT</code> |
| <code>MIDDLEINT</code> | <code>MEDIUMINT</code> |
| <code>NUMERIC</code> | <code>DECIMAL</code> |

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| a     | tinyint(1)   | YES  |     | NULL    |       |
| b     | double       | YES  |     | NULL    |       |
| c     | mediumtext   | YES  |     | NULL    |       |
| d     | decimal(10,0)| YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+
```

```
+-----+-----+-----+-----+-----+
4 rows in set (0.01 sec)
```

Chapter 12 Functions and Operators

Table of Contents

| | |
|--|------|
| 12.1 Function and Operator Reference | 1144 |
| 12.2 Type Conversion in Expression Evaluation | 1153 |
| 12.3 Operators | 1155 |
| 12.3.1 Operator Precedence | 1156 |
| 12.3.2 Comparison Functions and Operators | 1157 |

Expressions can be used at several points in **SQL** statements, such as in the **ORDER BY** or **HAVING** clauses of **SELECT** statements, in the **WHERE** clause of a **SELECT**, **DELETE**, or **UPDATE** statement, or in **SET** statements. Expressions can be written using literal values, column values, **NULL**, built-in functions, stored functions, user-defined functions, and operators. This chapter describes the functions and operators that are permitted for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in [Section 20.2, “Using Stored Routines”](#), and [Section 24.4, “Adding Functions to MySQL”](#). See [Section 9.2.5, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

An expression that contains **NULL** always produces a **NULL** value unless otherwise indicated in the documentation for a particular function or operator.

Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` option. (See [Section 5.1.10, “Server SQL Modes”](#).) Individual client programs can request this behavior by using the `CLIENT_IGNORE_SPACE` option for `mysql_real_connect()`. In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the `mysql` program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----+
| mod(29,9) |
+-----+
|         2 |
+-----+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
-> 2
```

12.1 Function and Operator Reference

Table 12.1 Functions and Operators

| Name | Description |
|--------|--------------------------------|
| & | Bitwise AND |
| > | Greater than operator |
| >> | Right shift |
| >= | Greater than or equal operator |
| < | Less than operator |
| <>, != | Not equal operator |
| << | Left shift |
| <= | Less than or equal operator |
| <=> | NULL-safe equal to operator |
| %, MOD | Modulo operator |
| * | Multiplication operator |
| + | Addition operator |
| - | Minus operator |

| Name | Description |
|-------------------------------------|--|
| - | Change the sign of the argument |
| / | Division operator |
| := | Assign a value |
| = | Assign a value (as part of a SET statement, or as part of the SET clause in an UPDATE statement) |
| = | Equal operator |
| ^ | Bitwise XOR |
| ABS() | Return the absolute value |
| ACOS() | Return the arc cosine |
| ADDDATE() | Add time values (intervals) to a date value |
| ADDTIME() | Add time |
| AES_DECRYPT() | Decrypt using AES |
| AES_ENCRYPT() | Encrypt using AES |
| AND, && | Logical AND |
| Area() | Return Polygon or MultiPolygon area |
| AsBinary(), AsWKB() | Convert from internal geometry format to WKB |
| ASCII() | Return numeric value of left-most character |
| ASIN() | Return the arc sine |
| AsText(), AsWKT() | Convert from internal geometry format to WKT |
| ATAN() | Return the arc tangent |
| ATAN2(), ATAN() | Return the arc tangent of the two arguments |
| AVG() | Return the average value of the argument |
| BENCHMARK() | Repeatedly execute an expression |
| BETWEEN ... AND ... | Whether a value is within a range of values |
| BIN() | Return a string containing binary representation of a number |
| BINARY | Cast a string to a binary string |
| BIT_AND() | Return bitwise AND |
| BIT_COUNT() | Return the number of bits that are set |
| BIT_LENGTH() | Return length of argument in bits |
| BIT_OR() | Return bitwise OR |
| BIT_XOR() | Return bitwise XOR |
| CASE | Case operator |
| CAST() | Cast a value as a certain type |
| CEIL() | Return the smallest integer value not less than the argument |
| CEILING() | Return the smallest integer value not less than the argument |
| Centroid() | Return centroid as a point |
| CHAR() | Return the character for each integer passed |
| CHAR_LENGTH() | Return number of characters in argument |
| CHARACTER_LENGTH() | Synonym for CHAR_LENGTH() |
| CHARSET() | Return the character set of the argument |
| COALESCE() | Return the first non-NULL argument |

| Name | Description |
|--|--|
| <code>COERCIBILITY()</code> | Return the collation coercibility value of the string argument |
| <code>COLLATION()</code> | Return the collation of the string argument |
| <code>COMPRESS()</code> | Return result as a binary string |
| <code>CONCAT()</code> | Return concatenated string |
| <code>CONCAT_WS()</code> | Return concatenate with separator |
| <code>CONNECTION_ID()</code> | Return the connection ID (thread ID) for the connection |
| <code>Contains()</code> | Whether MBR of one geometry contains MBR of another |
| <code>CONV()</code> | Convert numbers between different number bases |
| <code>CONVERT()</code> | Cast a value as a certain type |
| <code>CONVERT_TZ()</code> | Convert from one time zone to another |
| <code>COS()</code> | Return the cosine |
| <code>COT()</code> | Return the cotangent |
| <code>COUNT()</code> | Return a count of the number of rows returned |
| <code>COUNT(DISTINCT)</code> | Return the count of a number of different values |
| <code>CRC32()</code> | Compute a cyclic redundancy check value |
| <code>Crosses()</code> | Whether one geometry crosses another |
| <code>CURDATE()</code> | Return the current date |
| <code>CURRENT_DATE()</code> , <code>CURRENT_DATE</code> | Synonyms for <code>CURDATE()</code> |
| <code>CURRENT_TIME()</code> , <code>CURRENT_TIME</code> | Synonyms for <code>CURTIME()</code> |
| <code>CURRENT_TIMESTAMP()</code> , <code>CURRENT_TIMESTAMP</code> | Synonyms for <code>NOW()</code> |
| <code>CURRENT_USER()</code> , <code>CURRENT_USER</code> | The authenticated user name and host name |
| <code>CURTIME()</code> | Return the current time |
| <code>DATABASE()</code> | Return the default (current) database name |
| <code>DATE()</code> | Extract the date part of a date or datetime expression |
| <code>DATE_ADD()</code> | Add time values (intervals) to a date value |
| <code>DATE_FORMAT()</code> | Format date as specified |
| <code>DATE_SUB()</code> | Subtract a time value (interval) from a date |
| <code>DATEDIFF()</code> | Subtract two dates |
| <code>DAY()</code> | Synonym for <code>DAYOFMONTH()</code> |
| <code>DAYNAME()</code> | Return the name of the weekday |
| <code>DAYOFMONTH()</code> | Return the day of the month (0-31) |
| <code>DAYOFWEEK()</code> | Return the weekday index of the argument |
| <code>DAYOFYEAR()</code> | Return the day of the year (1-366) |
| <code>DECODE()</code> | Decode a string encrypted using <code>ENCODE()</code> |
| <code>DEFAULT()</code> | Return the default value for a table column |
| <code>DEGREES()</code> | Convert radians to degrees |
| <code>DES_DECRYPT()</code> | Decrypt a string |
| <code>DES_ENCRYPT()</code> | Encrypt a string |
| <code>Dimension()</code> | Dimension of geometry |
| <code>Disjoint()</code> | Whether MBRs of two geometries are disjoint |

| Name | Description |
|---|--|
| DIV | Integer division |
| ELT() | Return string at index number |
| ENCODE() | Encode a string |
| ENCRYPT() | Encrypt a string |
| EndPoint() | End Point of LineString |
| Envelope() | Return MBR of geometry |
| Equals() | Whether MBRs of two geometries are equal |
| EXP() | Raise to the power of |
| EXPORT_SET() | Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string |
| ExteriorRing() | Return exterior ring of Polygon |
| EXTRACT() | Extract part of a date |
| ExtractValue() | Extract a value from an XML string using XPath notation |
| FIELD() | Index (position) of first argument in subsequent arguments |
| FIND_IN_SET() | Index (position) of first argument within second argument |
| FLOOR() | Return the largest integer value not greater than the argument |
| FORMAT() | Return a number formatted to specified number of decimal places |
| FOUND_ROWS() | For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause |
| FROM_DAYS() | Convert a day number to a date |
| FROM_UNIXTIME() | Format Unix timestamp as a date |
| GeomCollFromText(), GeometryCollectionFromText() | Return geometry collection from WKT |
| GeomCollFromWKB(), GeometryCollectionFromWKB() | Return geometry collection from WKB |
| GeometryCollection() | Construct geometry collection from geometries |
| GeometryN() | Return N-th geometry from geometry collection |
| GeometryType() | Return name of geometry type |
| GeomFromText(), GeometryFromText() | Return geometry from WKT |
| GeomFromWKB(), GeometryFromWKB() | Return geometry from WKB |
| GET_FORMAT() | Return a date format string |
| GET_LOCK() | Get a named lock |
| GLength() | Return length of LineString |
| GREATEST() | Return the largest argument |
| GROUP_CONCAT() | Return a concatenated string |
| HEX() | Hexadecimal representation of decimal or string value |
| HOUR() | Extract the hour |
| IF() | If/else construct |

| Name | Description |
|---|---|
| IFNULL() | Null if/else construct |
| IN() | Whether a value is within a set of values |
| INET_ATON() | Return the numeric value of an IP address |
| INET_NTOA() | Return the IP address from a numeric value |
| INSERT() | Insert substring at specified position up to specified number of characters |
| INSTR() | Return the index of the first occurrence of substring |
| InteriorRingN() | Return N-th interior ring of Polygon |
| Intersects() | Whether MBRs of two geometries intersect |
| INTERVAL() | Return the index of the argument that is less than the first argument |
| IS | Test a value against a boolean |
| IS_FREE_LOCK() | Whether the named lock is free |
| IS NOT | Test a value against a boolean |
| IS NOT NULL | NOT NULL value test |
| IS NULL | NULL value test |
| IS_USED_LOCK() | Whether the named lock is in use; return connection identifier if true |
| IsClosed() | Whether a geometry is closed and simple |
| IsEmpty() | Placeholder function |
| ISNULL() | Test whether the argument is NULL |
| IsSimple() | Whether a geometry is simple |
| LAST_DAY | Return the last day of the month for the argument |
| LAST_INSERT_ID() | Value of the AUTOINCREMENT column for the last INSERT |
| LCASE() | Synonym for LOWER() |
| LEAST() | Return the smallest argument |
| LEFT() | Return the leftmost number of characters as specified |
| LENGTH() | Return the length of a string in bytes |
| LIKE | Simple pattern matching |
| LineFromText(), LineStringFromText() | Construct LineString from WKT |
| LineFromWKB(), LineStringFromWKB() | Construct LineString from WKB |
| LineString() | Construct LineString from Point values |
| LN() | Return the natural logarithm of the argument |
| LOAD_FILE() | Load the named file |
| LOCALTIME(), LOCALTIME | Synonym for NOW() |
| LOCALTIMESTAMP, LOCALTIMESTAMP() | Synonym for NOW() |
| LOCATE() | Return the position of the first occurrence of substring |
| LOG() | Return the natural logarithm of the first argument |
| LOG10() | Return the base-10 logarithm of the argument |

| Name | Description |
|---|---|
| LOG2 () | Return the base-2 logarithm of the argument |
| LOWER () | Return the argument in lowercase |
| LPAD () | Return the string argument, left-padded with the specified string |
| LTRIM () | Remove leading spaces |
| MAKE_SET () | Return a set of comma-separated strings that have the corresponding bit in bits set |
| MAKEDATE () | Create a date from the year and day of year |
| MAKETIME () | Create time from hour, minute, second |
| MASTER_POS_WAIT () | Block until the slave has read and applied all updates up to the specified position |
| MATCH | Perform full-text search |
| MAX () | Return the maximum value |
| MBRContains () | Whether MBR of one geometry contains MBR of another |
| MBRDisjoint () | Whether MBRs of two geometries are disjoint |
| MBREqual () | Whether MBRs of two geometries are equal |
| MBRIntersects () | Whether MBRs of two geometries intersect |
| MBROverlaps () | Whether MBRs of two geometries overlap |
| MBRTouches () | Whether MBRs of two geometries touch |
| MBRWithin () | Whether MBR of one geometry is within MBR of another |
| MD5 () | Calculate MD5 checksum |
| MICROSECOND () | Return the microseconds from argument |
| MID () | Return a substring starting from the specified position |
| MIN () | Return the minimum value |
| MINUTE () | Return the minute from the argument |
| MLineFromText (), MultiLineStringFromText () | Construct MultiLineString from WKT |
| MLineFromWKB (), MultiLineStringFromWKB () | Construct MultiLineString from WKB |
| MOD () | Return the remainder |
| MONTH () | Return the month from the date passed |
| MONTHNAME () | Return the name of the month |
| MPointFromText (), MultiPointFromText () | Construct MultiPoint from WKT |
| MPointFromWKB (), MultiPointFromWKB () | Construct MultiPoint from WKB |
| MPolyFromText (), MultiPolygonFromText () | Construct MultiPolygon from WKT |
| MPolyFromWKB (), MultiPolygonFromWKB () | Construct MultiPolygon from WKB |
| MultiLineString () | Construct MultiLineString from LineString values |
| MultiPoint () | Construct MultiPoint from Point values |
| MultiPolygon () | Construct MultiPolygon from Polygon values |

| Name | Description |
|--------------------------------------|--|
| NAME_CONST() | Cause the column to have the given name |
| NOT, ! | Negates value |
| NOT BETWEEN ... AND ... | Whether a value is not within a range of values |
| NOT IN() | Whether a value is not within a set of values |
| NOT LIKE | Negation of simple pattern matching |
| NOT REGEXP | Negation of REGEXP |
| NOW() | Return the current date and time |
| NULLIF() | Return NULL if expr1 = expr2 |
| NumGeometries() | Return number of geometries in geometry collection |
| NumInteriorRings() | Return number of interior rings in Polygon |
| NumPoints() | Return number of points in LineString |
| OCT() | Return a string containing octal representation of a number |
| OCTET_LENGTH() | Synonym for LENGTH() |
| OLD_PASSWORD() | Return the value of the pre-4.1 implementation of PASSWORD |
| OR, | Logical OR |
| ORD() | Return character code for leftmost character of the argument |
| Overlaps() | Whether MBRs of two geometries overlap |
| PASSWORD() | Calculate and return a password string |
| PERIOD_ADD() | Add a period to a year-month |
| PERIOD_DIFF() | Return the number of months between periods |
| PI() | Return the value of pi |
| Point() | Construct Point from coordinates |
| PointFromText() | Construct Point from WKT |
| PointFromWKB() | Construct Point from WKB |
| PointN() | Return N-th point from LineString |
| PolyFromText(), PolygonFromText() | Construct Polygon from WKT |
| PolyFromWKB(), PolygonFromWKB() | Construct Polygon from WKB |
| Polygon() | Construct Polygon from LineString arguments |
| POSITION() | Synonym for LOCATE() |
| POW() | Return the argument raised to the specified power |
| POWER() | Return the argument raised to the specified power |
| PROCEDURE ANALYSE() | Analyze the results of a query |
| QUARTER() | Return the quarter from a date argument |
| QUOTE() | Escape the argument for use in an SQL statement |
| RADIANS() | Return argument converted to radians |
| RAND() | Return a random floating-point value |
| REGEXP | Whether string matches regular expression |
| RELEASE_LOCK() | Release the named lock |
| REPEAT() | Repeat a string the specified number of times |

| Name | Description |
|---------------------|--|
| REPLACE () | Replace occurrences of a specified string |
| REVERSE () | Reverse the characters in a string |
| RIGHT () | Return the specified rightmost number of characters |
| RLIKE | Whether string matches regular expression |
| ROUND () | Round the argument |
| ROW_COUNT () | The number of rows updated |
| RPAD () | Append string the specified number of times |
| RTRIM () | Remove trailing spaces |
| SCHEMA () | Synonym for DATABASE() |
| SEC_TO_TIME () | Converts seconds to 'hh:mm:ss' format |
| SECOND () | Return the second (0-59) |
| SESSION_USER () | Synonym for USER() |
| SHA1 (), SHA () | Calculate an SHA-1 160-bit checksum |
| SHA2 () | Calculate an SHA-2 checksum |
| SIGN () | Return the sign of the argument |
| SIN () | Return the sine of the argument |
| SLEEP () | Sleep for a number of seconds |
| SOUNDEX () | Return a soundex string |
| SOUNDS LIKE | Compare sounds |
| SPACE () | Return a string of the specified number of spaces |
| SQRT () | Return the square root of the argument |
| SRID () | Return spatial reference system ID for geometry |
| StartPoint () | Start Point of LineString |
| STD () | Return the population standard deviation |
| STDDEV () | Return the population standard deviation |
| STDDEV_POP () | Return the population standard deviation |
| STDDEV_SAMP () | Return the sample standard deviation |
| STR_TO_DATE () | Convert a string to a date |
| STRCMP () | Compare two strings |
| SUBDATE () | Synonym for DATE_SUB() when invoked with three arguments |
| SUBSTR () | Return the substring as specified |
| SUBSTRING () | Return the substring as specified |
| SUBSTRING_INDEX () | Return a substring from a string before the specified number of occurrences of the delimiter |
| SUBTIME () | Subtract times |
| SUM () | Return the sum |
| SYSDATE () | Return the time at which the function executes |
| SYSTEM_USER () | Synonym for USER() |
| TAN () | Return the tangent of the argument |
| TIME () | Extract the time portion of the expression passed |

| Name | Description |
|-------------------------|---|
| TIME_FORMAT () | Format as time |
| TIME_TO_SEC () | Return the argument converted to seconds |
| TIMEDIFF () | Subtract time |
| TIMESTAMP () | With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments |
| TIMESTAMPADD () | Add an interval to a datetime expression |
| TIMESTAMPDIFF () | Subtract an interval from a datetime expression |
| TO_DAYS () | Return the date argument converted to days |
| TO_SECONDS () | Return the date or datetime argument converted to seconds since Year 0 |
| Touches () | Whether one geometry touches another |
| TRIM () | Remove leading and trailing spaces |
| TRUNCATE () | Truncate to specified number of decimal places |
| UCASE () | Synonym for UPPER() |
| UNCOMPRESS () | Uncompress a string compressed |
| UNCOMPRESSED_LENGTH () | Return the length of a string before compression |
| UNHEX () | Return a string containing hex representation of a number |
| UNIX_TIMESTAMP () | Return a Unix timestamp |
| UpdateXML () | Return replaced XML fragment |
| UPPER () | Convert to uppercase |
| USER () | The user name and host name provided by the client |
| UTC_DATE () | Return the current UTC date |
| UTC_TIME () | Return the current UTC time |
| UTC_TIMESTAMP () | Return the current UTC date and time |
| UUID () | Return a Universal Unique Identifier (UUID) |
| UUID_SHORT () | Return an integer-valued universal identifier |
| VALUES () | Define the values to be used during an INSERT |
| VAR_POP () | Return the population standard variance |
| VAR_SAMP () | Return the sample variance |
| VARIANCE () | Return the population standard variance |
| VERSION () | Return a string that indicates the MySQL server version |
| WEEK () | Return the week number |
| WEEKDAY () | Return the weekday index |
| WEEKOFYEAR () | Return the calendar week of the date (1-53) |
| Within () | Whether MBR of one geometry is within MBR of another |
| X () | Return X coordinate of Point |
| XOR | Logical XOR |
| Y () | Return Y coordinate of Point |
| YEAR () | Return the year |
| YEARWEEK () | Return the year and week |
| | Bitwise OR |

| Name | Description |
|------|-------------------|
| ~ | Bitwise inversion |

12.2 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts strings to numbers as necessary, and vice versa.

```
mysql> SELECT 1+'1';
-> 2
mysql> SELECT CONCAT(2,' test');
-> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST()` function. Conversion occurs implicitly with the `CONCAT()` function because it expects string arguments.

```
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
-> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
-> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to `CREATE TABLE ... SELECT` statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL`-safe `<=>` equality comparison operator. For `NULL <=> NULL`, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. This is not done for the arguments to `IN()`. To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type.
- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.
- In all other cases, the arguments are compared as floating-point (real) numbers. For example, a comparison of string and numeric operands takes places as a comparison of floating-point numbers.

For information about conversion of values from one temporal type to another, see [Section 11.2.8, “Conversion Between Date and Time Types”](#).

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
-> 0
mysql> SELECT 7 > '6x';
-> 1
mysql> SELECT 0 > 'x6';
-> 0
mysql> SELECT 0 = 'x6';
-> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If `str_col` is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value `1`, such as `'1'`, `' 1'`, or `'1a'`.

Comparisons that use floating-point numbers (or values that are converted to floating-point numbers) are approximate because such numbers are inexact. This might lead to results that appear inconsistent:

```
mysql> SELECT '18015376320243458' = 18015376320243458;
-> 1
mysql> SELECT '18015376320243459' = 18015376320243459;
-> 0
```

Such results can occur because the values are converted to floating-point numbers, which have only 53 bits of precision and are subject to rounding:

```
mysql> SELECT '18015376320243459'+0.0;
-> 1.8015376320243e+16
```

Furthermore, the conversion from string to floating-point and from integer to floating-point do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications.

The results shown will vary on different systems, and can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value is not converted implicitly to a float-point number:

```
mysql> SELECT CAST('18015376320243459' AS UNSIGNED) = 18015376320243459;
-> 1
```

For more information about floating-point comparisons, see [Section B.4.4.8, "Problems with Floating-Point Values"](#).

The server includes `dtoa`, a conversion library that provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT/DOUBLE`) numbers:

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.
- Accurate representation of values in cases where results previously did not provide sufficient precision, such as for values close to IEEE limits.
- Conversion of numbers to string format with the best possible precision. The precision of `dtoa` is always the same or better than that of the standard C library functions.

Because the conversions produced by this library differ in some cases from non-`dtoa` results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

The `dtoa` library provides conversions with the following properties. `D` represents a value with a `DECIMAL` or string representation, and `F` represents a floating-point number in native binary (IEEE) format.

- `F -> D` conversion is done with the best possible precision, returning `D` as the shortest string that yields `F` when read back in and rounded to the nearest value in native binary format as specified by IEEE.

| Name | Description |
|--------------------------------------|---|
| <code>:=</code> | Assign a value |
| <code>=</code> | Assign a value (as part of a <code>SET</code> statement, or as part of the <code>SET</code> clause in an <code>UPDATE</code> statement) |
| <code>=</code> | Equal operator |
| <code>^</code> | Bitwise XOR |
| <code>AND, &&</code> | Logical AND |
| <code>BETWEEN ... AND ...</code> | Whether a value is within a range of values |
| <code>BINARY</code> | Cast a string to a binary string |
| <code>CASE</code> | Case operator |
| <code>DIV</code> | Integer division |
| <code>IN()</code> | Whether a value is within a set of values |
| <code>IS</code> | Test a value against a boolean |
| <code>IS NOT</code> | Test a value against a boolean |
| <code>IS NOT NULL</code> | NOT NULL value test |
| <code>IS NULL</code> | NULL value test |
| <code>LIKE</code> | Simple pattern matching |
| <code>NOT, !</code> | Negates value |
| <code>NOT BETWEEN ... AND ...</code> | Whether a value is not within a range of values |
| <code>NOT IN()</code> | Whether a value is not within a set of values |
| <code>NOT LIKE</code> | Negation of simple pattern matching |
| <code>NOT REGEXP</code> | Negation of REGEXP |
| <code>OR, </code> | Logical OR |
| <code>REGEXP</code> | Whether string matches regular expression |
| <code>RLIKE</code> | Whether string matches regular expression |
| <code>SOUNDS LIKE</code> | Compare sounds |
| <code>XOR</code> | Logical XOR |
| <code> </code> | Bitwise OR |
| <code>~</code> | Bitwise inversion |

12.3.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```

INTERVAL
BINARY, COLLATE
!
- (unary minus), ~ (unary bit inversion)
^
*, /, DIV, %, MOD
-, +
<<, >>
&
|
= (comparison), <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
AND, &&
XOR
OR, ||

```

```
= (assignment), :=
```

The precedence of = depends on whether it is used as a comparison operator (=) or as an assignment operator (:=). When used as a comparison operator, it has the same precedence as <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, and IN(). When used as an assignment operator, it has the same precedence as :=, Section 13.7.4.1, “SET Syntax for Variable Assignment”, and Section 9.4, “User-Defined Variables”, explain how MySQL determines which interpretation of = should apply.

For operators that occur at the same precedence level within an expression, evaluation proceeds left to right, with the exception that assignments evaluate right to left.

The precedence and meaning of some operators depends on the SQL mode:

- By default, || is a logical OR operator. With PIPES_AS_CONCAT enabled, || is string concatenation, with a precedence between ^ and the unary operators.
- By default, ! has a higher precedence than NOT. With HIGH_NOT_PRECEDENCE enabled, ! and NOT have the same precedence.

See Section 5.1.10, “Server SQL Modes”.

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```
mysql> SELECT 1+2*3;
-> 7
mysql> SELECT (1+2)*3;
-> 9
```

12.3.2 Comparison Functions and Operators

Table 12.3 Comparison Operators

| Name | Description |
|---------------------|---|
| > | Greater than operator |
| >= | Greater than or equal operator |
| < | Less than operator |
| <>, != | Not equal operator |
| <= | Less than or equal operator |
| <=> | NULL-safe equal to operator |
| = | Equal operator |
| BETWEEN ... AND ... | Whether a value is within a range of values |
| COALESCE() | Return the first non-NULL argument |
| GREATEST() | Return the largest argument |
| IN() | Whether a value is within a set of values |
| INTERVAL() | Return the index of the argument that is less than the first argument |
| IS | Test a value against a boolean |
| IS NOT | Test a value against a boolean |
| IS NOT NULL | NOT NULL value test |
| IS NULL | NULL value test |
| ISNULL() | Test whether the argument is NULL |

| Name | Description |
|--------------------------------------|---|
| <code>LEAST()</code> | Return the smallest argument |
| <code>LIKE</code> | Simple pattern matching |
| <code>NOT BETWEEN ... AND ...</code> | Whether a value is not within a range of values |
| <code>NOT IN()</code> | Whether a value is not within a set of values |
| <code>NOT LIKE</code> | Negation of simple pattern matching |
| <code>STRCMP()</code> | Compare two strings |

Comparison operations result in a value of `1` (`TRUE`), `0` (`FALSE`), or `NULL`. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

```
= > < >= <= <> !=
```

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see [Section 13.2.10.5, “Row Subqueries”](#).

Some of the functions in this section return values other than `1` (`TRUE`), `0` (`FALSE`), or `NULL`. `LEAST()` and `GREATEST()` are examples of such functions; [Section 12.2, “Type Conversion in Expression Evaluation”](#), describes the rules for comparison operations performed by these and similar functions for determining their return values.

To convert a value to a specific type for comparison purposes, you can use the `CAST()` function. String values can be converted to a different character set using `CONVERT()`. See [Section 12.10, “Cast Functions and Operators”](#).

By default, string comparisons are not case-sensitive and use the current character set. The default is `latin1` (cp1252 West European), which also works well for English.

- `=`

Equal:

```
mysql> SELECT 1 = 0;
-> 0
mysql> SELECT '0' = 0;
-> 1
mysql> SELECT '0.0' = 0;
-> 1
mysql> SELECT '0.01' = 0;
-> 0
mysql> SELECT '.01' = 0.01;
-> 1
```

For row comparisons, `(a, b) = (x, y)` is equivalent to:

```
(a = x) AND (b = y)
```

- `<=>`

`NULL`-safe equal. This operator performs an equality comparison like the `=` operator, but returns `1` rather than `NULL` if both operands are `NULL`, and `0` rather than `NULL` if one operand is `NULL`.

The `<=>` operator is equivalent to the standard SQL `IS NOT DISTINCT FROM` operator.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
-> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
-> 1, NULL, NULL
```

For row comparisons, $(a, b) <=> (x, y)$ is equivalent to:

```
(a <=> x) AND (b <=> y)
```

- $<>, !=$

Not equal:

```
mysql> SELECT '.01' <> '0.01';
-> 1
mysql> SELECT .01 <> '0.01';
-> 0
mysql> SELECT 'zapp' <> 'zapp';
-> 1
```

For row comparisons, $(a, b) <> (x, y)$ and $(a, b) != (x, y)$ are equivalent to:

```
(a <> x) OR (b <> y)
```

- $<=$

Less than or equal:

```
mysql> SELECT 0.1 <= 2;
-> 1
```

For row comparisons, $(a, b) <= (x, y)$ is equivalent to:

```
(a < x) OR ((a = x) AND (b <= y))
```

- $<$

Less than:

```
mysql> SELECT 2 < 2;
-> 0
```

For row comparisons, $(a, b) < (x, y)$ is equivalent to:

```
(a < x) OR ((a = x) AND (b < y))
```

- $>=$

Greater than or equal:

```
mysql> SELECT 2 >= 2;
-> 1
```

For row comparisons, $(a, b) >= (x, y)$ is equivalent to:

```
(a > x) OR ((a = x) AND (b >= y))
```

- $>$

Greater than:

```
mysql> SELECT 2 > 2;
-> 0
```

For row comparisons, $(a, b) > (x, y)$ is equivalent to:

```
(a > x) OR ((a = x) AND (b > y))
```

- `expr BETWEEN min AND max`

If `expr` is greater than or equal to `min` and `expr` is less than or equal to `max`, `BETWEEN` returns 1, otherwise it returns 0. This is equivalent to the expression `(min <= expr AND expr <= max)` if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in [Section 12.2, “Type Conversion in Expression Evaluation”](#), but applied to all the three arguments.

```
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 and 1;
-> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
-> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0
```

For best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type. Examples: If you compare a `DATETIME` to two `DATE` values, convert the `DATE` values to `DATETIME` values. If you use a string constant such as `'2001-1-1'` in a comparison to a `DATE`, cast the string to a `DATE`.

- `expr NOT BETWEEN min AND max`

This is the same as `NOT (expr BETWEEN min AND max)`.

- `COALESCE(value,...)`

Returns the first non-`NULL` value in the list, or `NULL` if there are no non-`NULL` values.

The return type of `COALESCE()` is the aggregated type of the argument types.

```
mysql> SELECT COALESCE(NULL,1);
-> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
-> NULL
```

- `GREATEST(value1,value2,...)`

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for `LEAST()`.

```
mysql> SELECT GREATEST(2,0);
-> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
-> 767.0
mysql> SELECT GREATEST('B','A','C');
-> 'C'
```

`GREATEST()` returns `NULL` if any argument is `NULL`.

- `expr IN (value,...)`

Returns 1 (true) if `expr` is equal to any of the values in the `IN()` list, else returns 0 (false).

Type conversion takes place according to the rules described in [Section 12.2, “Type Conversion in Expression Evaluation”](#), applied to all the arguments. If no type conversion is needed for the values in the `IN()` list, they are all constants of the same type, and `expr` can be compared to each of them as a value of the same type (possibly after type conversion), an optimization takes place. The values the list are sorted and the search for `expr` is done using a binary search, which makes the `IN()` operation very quick.

```
mysql> SELECT 2 IN (0,3,5,7);
-> 0
```

```
mysql> SELECT 'wefwf' IN ('wee', 'wefwf', 'weg');
-> 1
```

`IN()` can be used to compare row constructors:

```
mysql> SELECT (3,4) IN ((1,2), (3,4));
-> 1
mysql> SELECT (3,4) IN ((1,2), (3,5));
-> 0
```

You should never mix quoted and unquoted values in an `IN()` list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an `IN()` expression like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
```

Instead, write it like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
```

Implicit type conversion may produce nonintuitive results:

```
mysql> SELECT 'a' IN (0), 0 IN ('b');
-> 1, 1
```

In both cases, the comparison values are converted to floating-point values, yielding 0.0 in each case, and a comparison result of 1 (true).

The number of values in the `IN()` list is only limited by the `max_allowed_packet` value.

To comply with the SQL standard, `IN()` returns `NULL` not only if the expression on the left hand side is `NULL`, but also if no match is found in the list and one of the expressions in the list is `NULL`.

`IN()` syntax can also be used to write certain types of subqueries. See [Section 13.2.10.3, “Subqueries with ANY, IN, or SOME”](#).

- `expr NOT IN (value,...)`

This is the same as `NOT (expr IN (value,...))`.

- `INTERVAL(N,N1,N2,N3,...)`

Returns 0 if $N < N1$, 1 if $N < N2$ and so on or -1 if N is `NULL`. All arguments are treated as integers. It is required that $N1 < N2 < N3 < \dots < Nn$ for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- `IS boolean_value`

Tests a value against a boolean value, where `boolean_value` can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
```

- `IS NOT boolean_value`

Tests a value against a boolean value, where `boolean_value` can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- `IS NULL`

Tests whether a value is `NULL`.

```
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using `IS NULL`:

- If `sql_auto_is_null` variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 12.15, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison can be disabled by setting `sql_auto_is_null = 0`. See [Section 5.1.7, “Server System Variables”](#).

The default value of `sql_auto_is_null` is 0.

- For `DATE` and `DATETIME` columns that are declared as `NOT NULL`, you can find the special date `'0000-00-00'` by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a `'0000-00-00'` date value.

See [Obtaining Auto-Increment Values](#), and the description for the `FLAG_AUTO_IS_NULL` option at [Connector/ODBC Connection Parameters](#).

- `IS NOT NULL`

Tests whether a value is not `NULL`.

```
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
```

- `ISNULL(expr)`

If `expr` is `NULL`, `ISNULL()` returns 1, otherwise it returns 0.

```
mysql> SELECT ISNULL(1+1);
-> 0
mysql> SELECT ISNULL(1/0);
-> 1
```

`ISNULL()` can be used instead of `=` to test whether a value is `NULL`. (Comparing a value to `NULL` using `=` always yields `NULL`.)

The `ISNULL()` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`.

- `LEAST(value1,value2,...)`

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If any argument is `NULL`, the result is `NULL`. No comparison is needed.
- If all arguments are integer-valued, they are compared as integers.
- If at least one argument is double precision, they are compared as double-precision values. Otherwise, if at least one argument is a `DECIMAL` value, they are compared as `DECIMAL` values.
- If the arguments comprise a mix of numbers and strings, they are compared as numbers.
- If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
- In all other cases, the arguments are compared as binary strings.

The return type of `LEAST()` is the aggregated type of the comparison argument types.

```
mysql> SELECT LEAST(2,0);
-> 0
mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
-> 3.0
mysql> SELECT LEAST('B','A','C');
-> 'A'
```

12.3.3 Logical Operators

Table 12.4 Logical Operators

| Name | Description |
|------------------------------|---------------|
| <code>AND, &&</code> | Logical AND |
| <code>NOT, !</code> | Negates value |
| <code>OR, </code> | Logical OR |
| <code>XOR</code> | Logical XOR |

In SQL, all logical operators evaluate to `TRUE`, `FALSE`, or `NULL` (`UNKNOWN`). In MySQL, these are implemented as 1 (`TRUE`), 0 (`FALSE`), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any nonzero value for `TRUE`.

MySQL evaluates any nonzero, non-`NULL` value to `TRUE`. For example, the following statements all assess to `TRUE`:

```
mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1
```

- `NOT, !`

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is nonzero, and `NOT NULL` returns `NULL`.

```
mysql> SELECT NOT 10;
-> 0
mysql> SELECT NOT 0;
-> 1
mysql> SELECT NOT NULL;
-> NULL
```

```
mysql> SELECT !(1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1
```

The last example produces 1 because the expression evaluates the same way as $(!1)+1$.

- **AND, &&**

Logical AND. Evaluates to 1 if all operands are nonzero and not `NULL`, to 0 if one or more operands are 0, otherwise `NULL` is returned.

```
mysql> SELECT 1 AND 1;
-> 1
mysql> SELECT 1 AND 0;
-> 0
mysql> SELECT 1 AND NULL;
-> NULL
mysql> SELECT 0 AND NULL;
-> 0
mysql> SELECT NULL AND 0;
-> 0
```

- **OR, ||**

Logical OR. When both operands are non-`NULL`, the result is 1 if any operand is nonzero, and 0 otherwise. With a `NULL` operand, the result is 1 if the other operand is nonzero, and `NULL` otherwise. If both operands are `NULL`, the result is `NULL`.

```
mysql> SELECT 1 OR 1;
-> 1
mysql> SELECT 1 OR 0;
-> 1
mysql> SELECT 0 OR 0;
-> 0
mysql> SELECT 0 OR NULL;
-> NULL
mysql> SELECT 1 OR NULL;
-> 1
```

Note

If the `PIPES_AS_CONCAT` SQL mode is enabled, `||` signifies the SQL-standard string concatenation operator (like `CONCAT()`).

- **XOR**

Logical XOR. Returns `NULL` if either operand is `NULL`. For non-`NULL` operands, evaluates to 1 if an odd number of operands is nonzero, otherwise 0 is returned.

```
mysql> SELECT 1 XOR 1;
-> 0
mysql> SELECT 1 XOR 0;
-> 1
mysql> SELECT 1 XOR NULL;
-> NULL
mysql> SELECT 1 XOR 1 XOR 1;
-> 1
```

$a \text{ XOR } b$ is mathematically equal to $(a \text{ AND } (\text{NOT } b)) \text{ OR } ((\text{NOT } a) \text{ and } b)$.

12.3.4 Assignment Operators

Table 12.5 Assignment Operators

| Name | Description |
|-----------------|----------------|
| <code>:=</code> | Assign a value |

| Name | Description |
|------|--|
| = | Assign a value (as part of a SET statement, or as part of the SET clause in an UPDATE statement) |

- :=

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same [SET](#) statement. You can perform multiple assignments in the same statement.

Unlike =, the := operator is never interpreted as a comparison operator. This means you can use := in any valid SQL statement (not just in [SET](#) statements) to assign a value to a variable.

```
mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1

mysql> SELECT @var1:=COUNT(*) FROM t1;
-> 4
mysql> SELECT @var1;
-> 4
```

You can make value assignments using := in other statements besides [SELECT](#), such as [UPDATE](#), as shown here:

```
mysql> SELECT @var1;
-> 4
mysql> SELECT * FROM t1;
-> 1, 3, 5, 7

mysql> UPDATE t1 SET c1 = 2 WHERE c1 = @var1:= 1;
Query OK, 1 row affected (0.00 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT @var1;
-> 1
mysql> SELECT * FROM t1;
-> 2, 3, 5, 7
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the := operator, this is not recommended. [Section 9.4, "User-Defined Variables"](#), explains why you should avoid doing this.

- =

This operator is used to perform value assignments in two cases, described in the next two paragraphs.

Within a [SET](#) statement, = is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a [SET](#) statement, = is treated identically to :=.) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the

result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement.

In the `SET` clause of an `UPDATE` statement, `=` also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any `WHERE` conditions that are part of the `UPDATE` are met. You can make multiple assignments in the same `SET` clause of an `UPDATE` statement.

In any other context, `=` is treated as a [comparison operator](#).

```
mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1
```

For more information, see [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#), [Section 13.2.11, “UPDATE Statement”](#), and [Section 13.2.10, “Subqueries”](#).

12.4 Control Flow Functions

Table 12.6 Flow Control Operators

| Name | Description |
|-----------------------|---|
| <code>CASE</code> | Case operator |
| <code>IF()</code> | If/else construct |
| <code>IFNULL()</code> | Null if/else construct |
| <code>NULLIF()</code> | Return NULL if <code>expr1 = expr2</code> |

- `CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN result ...] [ELSE result] END`

```
CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END
```

The first `CASE` syntax returns the `result` for the first `value=compare_value` comparison that is true. The second syntax returns the result for the first condition that is true. If no comparison or condition is true, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

Note

The syntax of the `CASE expr` described here differs slightly from that of the SQL `CASE statement` described in [Section 13.6.5.1, “CASE Statement”](#), for use inside stored programs. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

The return type of a `CASE` expression result is the aggregated type of all result values.

```
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
->      WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
->      WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

- `IF(expr1,expr2,expr3)`

If *expr1* is TRUE (*expr1* <> 0 and *expr1* <> NULL), IF() returns *expr2*. Otherwise, it returns *expr3*.

Note

There is also an *IF statement*, which differs from the IF() function described here. See [Section 13.6.5.2, “IF Statement”](#).

If only one of *expr2* or *expr3* is explicitly NULL, the result type of the IF() function is the type of the non-NULL expression.

The default return type of IF() (which may matter when it is stored into a temporary table) is calculated as follows:

- If *expr2* or *expr3* produce a string, the result is a string.
If *expr2* and *expr3* are both strings, the result is case-sensitive if either string is case-sensitive.
- If *expr2* or *expr3* produce a floating-point value, the result is a floating-point value.
- If *expr2* or *expr3* produce an integer, the result is an integer.

```
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'
```

- IFNULL(*expr1*,*expr2*)

If *expr1* is not NULL, IFNULL() returns *expr1*; otherwise it returns *expr2*.

```
mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'
```

The default return type of IFNULL(*expr1*,*expr2*) is the more “general” of the two expressions, in the order STRING, REAL, or INTEGER. Consider the case of a table based on expressions or where MySQL must internally store a value returned by IFNULL() in a temporary table:

```
mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| test  | varbinary(4) | NO   |     |          |       |
+-----+-----+-----+-----+-----+
```

In this example, the type of the *test* column is VARBINARY(4) (a string type).

- NULLIF(*expr1*,*expr2*)

Returns NULL if *expr1* = *expr2* is true, otherwise returns *expr1*. This is the same as CASE WHEN *expr1* = *expr2* THEN NULL ELSE *expr1* END.

The return value has the same type as the first argument.

```
mysql> SELECT NULLIF(1,1);
```

```
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1
```

Note

MySQL evaluates *expr1* twice if the arguments are not equal.

12.5 Numeric Functions and Operators

Table 12.7 Numeric Functions and Operators

| Name | Description |
|-----------------------------------|--|
| <code>%</code> , <code>MOD</code> | Modulo operator |
| <code>*</code> | Multiplication operator |
| <code>+</code> | Addition operator |
| <code>-</code> | Minus operator |
| <code>-</code> | Change the sign of the argument |
| <code>/</code> | Division operator |
| <code>ABS()</code> | Return the absolute value |
| <code>ACOS()</code> | Return the arc cosine |
| <code>ASIN()</code> | Return the arc sine |
| <code>ATAN()</code> | Return the arc tangent |
| <code>ATAN2(), ATAN()</code> | Return the arc tangent of the two arguments |
| <code>CEIL()</code> | Return the smallest integer value not less than the argument |
| <code>CEILING()</code> | Return the smallest integer value not less than the argument |
| <code>CONV()</code> | Convert numbers between different number bases |
| <code>COS()</code> | Return the cosine |
| <code>COT()</code> | Return the cotangent |
| <code>CRC32()</code> | Compute a cyclic redundancy check value |
| <code>DEGREES()</code> | Convert radians to degrees |
| <code>DIV</code> | Integer division |
| <code>EXP()</code> | Raise to the power of |
| <code>FLOOR()</code> | Return the largest integer value not greater than the argument |
| <code>LN()</code> | Return the natural logarithm of the argument |
| <code>LOG()</code> | Return the natural logarithm of the first argument |
| <code>LOG10()</code> | Return the base-10 logarithm of the argument |
| <code>LOG2()</code> | Return the base-2 logarithm of the argument |
| <code>MOD()</code> | Return the remainder |
| <code>PI()</code> | Return the value of pi |
| <code>POW()</code> | Return the argument raised to the specified power |
| <code>POWER()</code> | Return the argument raised to the specified power |
| <code>RADIANS()</code> | Return argument converted to radians |
| <code>RAND()</code> | Return a random floating-point value |
| <code>ROUND()</code> | Round the argument |

| Name | Description |
|-------------------------|--|
| <code>SIGN()</code> | Return the sign of the argument |
| <code>SIN()</code> | Return the sine of the argument |
| <code>SQRT()</code> | Return the square root of the argument |
| <code>TAN()</code> | Return the tangent of the argument |
| <code>TRUNCATE()</code> | Truncate to specified number of decimal places |

12.5.1 Arithmetic Operators

Table 12.8 Arithmetic Operators

| Name | Description |
|---------------------|---------------------------------|
| <code>%, MOD</code> | Modulo operator |
| <code>*</code> | Multiplication operator |
| <code>+</code> | Addition operator |
| <code>-</code> | Minus operator |
| <code>-</code> | Change the sign of the argument |
| <code>/</code> | Division operator |
| <code>DIV</code> | Integer division |

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of `-`, `+`, and `*`, the result is calculated with `BIGINT` (64-bit) precision if both operands are integers.
- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is signed even if any operand is unsigned.
- If any of the operands of a `+`, `-`, `/`, `*`, `%` is a real or string value, the precision of the result is the precision of the operand with the maximum precision.
- In division performed with `/`, the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the `div_precision_increment` system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, resolves first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.60288653`).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See [Section 12.10, “Cast Functions and Operators”](#).

For information about handling of overflow in numeric expression evaluation, see [Section 11.1.7, “Out-of-Range and Overflow Handling”](#).

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use `DATE_ADD()`; see [Section 12.6, “Date and Time Functions”](#).

- `+`

Addition:

```
mysql> SELECT 3+5;
```

```
-> 8
```

- -

Subtraction:

```
mysql> SELECT 3-5;
-> -2
```

- -

Unary minus. This operator changes the sign of the operand.

```
mysql> SELECT - 2;
-> -2
```

Note

If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of -2^{63} .

- *

Multiplication:

```
mysql> SELECT 3*5;
-> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
-> 324518553658426726783156020576256.0
mysql> SELECT 18014398509481984*18014398509481984;
-> out-of-range error
```

The last expression produces an error because the result of the integer multiplication exceeds the 64-bit range of `BIGINT` calculations. (See [Section 11.1, “Numeric Data Types”](#).)

- /

Division:

```
mysql> SELECT 3/5;
-> 0.60
```

Division by zero produces a `NULL` result:

```
mysql> SELECT 102/(1-1);
-> NULL
```

A division is calculated with `BIGINT` arithmetic only if performed in a context where its result is converted to an integer.

- `DIV`

Integer division. Discards from the division result any fractional part to the right of the decimal point.

If either operand has a noninteger type, the operands are converted to `DECIMAL` and divided using `DECIMAL` arithmetic before converting the result to `BIGINT`. If the result exceeds `BIGINT` range, an error occurs.

```
mysql> SELECT 5 DIV 2, -5 DIV 2, 5 DIV -2, -5 DIV -2;
-> 2, -2, -2, 2
```

- `N % M, N MOD M`

Modulo operation. Returns the remainder of `N` divided by `M`. For more information, see the description for the `MOD()` function in [Section 12.5.2, “Mathematical Functions”](#).

12.5.2 Mathematical Functions

Table 12.9 Mathematical Functions

| Name | Description |
|----------------------------------|--|
| <code>ABS ()</code> | Return the absolute value |
| <code>ACOS ()</code> | Return the arc cosine |
| <code>ASIN ()</code> | Return the arc sine |
| <code>ATAN ()</code> | Return the arc tangent |
| <code>ATAN2 (), ATAN ()</code> | Return the arc tangent of the two arguments |
| <code>CEIL ()</code> | Return the smallest integer value not less than the argument |
| <code>CEILING ()</code> | Return the smallest integer value not less than the argument |
| <code>CONV ()</code> | Convert numbers between different number bases |
| <code>COS ()</code> | Return the cosine |
| <code>COT ()</code> | Return the cotangent |
| <code>CRC32 ()</code> | Compute a cyclic redundancy check value |
| <code>DEGREES ()</code> | Convert radians to degrees |
| <code>EXP ()</code> | Raise to the power of |
| <code>FLOOR ()</code> | Return the largest integer value not greater than the argument |
| <code>LN ()</code> | Return the natural logarithm of the argument |
| <code>LOG ()</code> | Return the natural logarithm of the first argument |
| <code>LOG10 ()</code> | Return the base-10 logarithm of the argument |
| <code>LOG2 ()</code> | Return the base-2 logarithm of the argument |
| <code>MOD ()</code> | Return the remainder |
| <code>PI ()</code> | Return the value of pi |
| <code>POW ()</code> | Return the argument raised to the specified power |
| <code>POWER ()</code> | Return the argument raised to the specified power |
| <code>RADIANS ()</code> | Return argument converted to radians |
| <code>RAND ()</code> | Return a random floating-point value |
| <code>ROUND ()</code> | Round the argument |
| <code>SIGN ()</code> | Return the sign of the argument |
| <code>SIN ()</code> | Return the sine of the argument |
| <code>SQRT ()</code> | Return the square root of the argument |
| <code>TAN ()</code> | Return the tangent of the argument |
| <code>TRUNCATE ()</code> | Truncate to specified number of decimal places |

All mathematical functions return `NULL` in the event of an error.

- `ABS (X)`

Returns the absolute value of `X`.

```
mysql> SELECT ABS(2);
-> 2
mysql> SELECT ABS(-32);
-> 32
```

This function is safe to use with `BIGINT` values.

- `ACOS(X)`

Returns the arc cosine of X , that is, the value whose cosine is X . Returns `NULL` if X is not in the range -1 to 1 .

```
mysql> SELECT ACOS(1);
      -> 0
mysql> SELECT ACOS(1.0001);
      -> NULL
mysql> SELECT ACOS(0);
      -> 1.5707963267949
```

- `ASIN(X)`

Returns the arc sine of X , that is, the value whose sine is X . Returns `NULL` if X is not in the range -1 to 1 .

```
mysql> SELECT ASIN(0.2);
      -> 0.20135792079033
mysql> SELECT ASIN('foo');

+-----+
| ASIN('foo') |
+-----+
|           0 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;

+-----+-----+-----+
| Level | Code | Message
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo'
+-----+-----+-----+
```

- `ATAN(X)`

Returns the arc tangent of X , that is, the value whose tangent is X .

```
mysql> SELECT ATAN(2);
      -> 1.1071487177941
mysql> SELECT ATAN(-2);
      -> -1.1071487177941
```

- `ATAN(Y, X)`, `ATAN2(Y, X)`

Returns the arc tangent of the two variables X and Y . It is similar to calculating the arc tangent of Y / X , except that the signs of both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN(-2,2);
      -> -0.78539816339745
mysql> SELECT ATAN2(PI(),0);
      -> 1.5707963267949
```

- `CEIL(X)`

`CEIL()` is a synonym for `CEILING()`.

- `CEILING(X)`

Returns the smallest integer value not less than X .

```
mysql> SELECT CEILING(1.23);
      -> 2
mysql> SELECT CEILING(-1.23);
```

```
-> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- `CONV(N, from_base, to_base)`

Converts numbers between different number bases. Returns a string representation of the number *N*, converted from base *from_base* to base *to_base*. Returns `NULL` if any argument is `NULL`. The argument *N* is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If *from_base* is a negative number, *N* is regarded as a signed number. Otherwise, *N* is treated as unsigned. `CONV()` works with 64-bit precision.

```
mysql> SELECT CONV('a',16,2);
      -> '1010'
mysql> SELECT CONV('6E',18,8);
      -> '172'
mysql> SELECT CONV(-17,10,-18);
      -> '-H'
mysql> SELECT CONV(10+'10'+ '10'+X'0a',10,10);
      -> '40'
```

- `COS(X)`

Returns the cosine of *X*, where *X* is given in radians.

```
mysql> SELECT COS(PI());
      -> -1
```

- `COT(X)`

Returns the cotangent of *X*.

```
mysql> SELECT COT(12);
      -> -1.5726734063977
mysql> SELECT COT(0);
      -> out-of-range error
```

- `CRC32(expr)`

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
      -> 3259397556
mysql> SELECT CRC32('mysql');
      -> 2501908538
```

- `DEGREES(X)`

Returns the argument *X*, converted from radians to degrees.

```
mysql> SELECT DEGREES(PI());
      -> 180
mysql> SELECT DEGREES(PI() / 2);
      -> 90
```

- `EXP(X)`

Returns the value of *e* (the base of natural logarithms) raised to the power of *X*. The inverse of this function is `LOG()` (using a single argument only) or `LN()`.

```
mysql> SELECT EXP(2);
      -> 7.3890560989307
mysql> SELECT EXP(-2);
      -> 0.13533528323661
```

```
mysql> SELECT EXP(0);
-> 1
```

- `FLOOR(X)`

Returns the largest integer value not greater than X .

```
mysql> SELECT FLOOR(1.23), FLOOR(-1.23);
-> 1, -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- `FORMAT(X,D)`

Formats the number X to a format like '#,###,###.##', rounded to D decimal places, and returns the result as a string. For details, see [Section 12.7, "String Functions and Operators"](#).

- `HEX(N_or_S)`

This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in [Section 12.7, "String Functions and Operators"](#), for details.

- `LN(X)`

Returns the natural logarithm of X ; that is, the base- e logarithm of X . If X is less than or equal to 0, then `NULL` is returned.

```
mysql> SELECT LN(2);
-> 0.69314718055995
mysql> SELECT LN(-2);
-> NULL
```

This function is synonymous with `LOG(X)`. The inverse of this function is the `EXP()` function.

- `LOG(X), LOG(B,X)`

If called with one parameter, this function returns the natural logarithm of X . If X is less than or equal to 0, then `NULL` is returned.

The inverse of this function (when called with a single argument) is the `EXP()` function.

```
mysql> SELECT LOG(2);
-> 0.69314718055995
mysql> SELECT LOG(-2);
-> NULL
```

If called with two parameters, this function returns the logarithm of X to the base B . If X is less than or equal to 0, or if B is less than or equal to 1, then `NULL` is returned.

```
mysql> SELECT LOG(2,65536);
-> 16
mysql> SELECT LOG(10,100);
-> 2
mysql> SELECT LOG(1,100);
-> NULL
```

`LOG(B,X)` is equivalent to `LOG(X) / LOG(B)`.

- `LOG2(X)`

Returns the base-2 logarithm of X .

```
mysql> SELECT LOG2(65536);
-> 16
mysql> SELECT LOG2(-100);
```

```
-> NULL
```

`LOG2()` is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression `LOG(X) / LOG(2)`.

- `LOG10(X)`

Returns the base-10 logarithm of *X*.

```
mysql> SELECT LOG10(2);
-> 0.30102999566398
mysql> SELECT LOG10(100);
-> 2
mysql> SELECT LOG10(-100);
-> NULL
```

`LOG10(X)` is equivalent to `LOG(10, X)`.

- `MOD(N,M), N % M, N MOD M`

Modulo operation. Returns the remainder of *N* divided by *M*.

```
mysql> SELECT MOD(234, 10);
-> 4
mysql> SELECT 253 % 7;
-> 1
mysql> SELECT MOD(29,9);
-> 2
mysql> SELECT 29 MOD 9;
-> 2
```

This function is safe to use with `BIGINT` values.

`MOD()` also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5,3);
-> 1.5
```

`MOD(N, 0)` returns `NULL`.

- `PI()`

Returns the value of π (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```
mysql> SELECT PI();
-> 3.141593
mysql> SELECT PI()+0.00000000000000000000;
-> 3.141592653589793116
```

- `POW(X,Y)`

Returns the value of *X* raised to the power of *Y*.

```
mysql> SELECT POW(2,2);
-> 4
mysql> SELECT POW(2,-2);
-> 0.25
```

- `POWER(X,Y)`

This is a synonym for `POW()`.

- `RADIANS(X)`

Returns the argument `X`, converted from degrees to radians. (Note that π radians equals 180 degrees.)

```
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

- `RAND([N])`

Returns a random floating-point value `v` in the range $0 \leq v < 1.0$. To obtain a random integer `R` in the range $i \leq R < j$, use the expression `FLOOR(i + RAND() * (j - i))`. For example, to obtain a random integer in the range the range $7 \leq R < 12$, use the following statement:

```
SELECT FLOOR(7 + (RAND() * 5));
```

If an integer argument `N` is specified, it is used as the seed value:

- With a constant initializer argument, the seed is initialized once when the statement is prepared, prior to execution.
- With a nonconstant initializer argument (such as a column name), the seed is initialized with the value for each invocation of `RAND()`.

One implication of this behavior is that for equal argument values, `RAND(N)` returns the same value each time, and thus produces a repeatable sequence of column values. In the following example, the sequence of values produced by `RAND(3)` is the same both places it occurs.

```
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i | RAND() |
+-----+-----+
| 1 | 0.61914388706828 |
| 2 | 0.93845168309142 |
| 3 | 0.83482678498591 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i | RAND(3) |
+-----+-----+
| 1 | 0.90576975597606 |
| 2 | 0.37307905813035 |
| 3 | 0.14808605345719 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i | RAND() |
+-----+-----+
| 1 | 0.35877890638893 |
| 2 | 0.28941420772058 |
| 3 | 0.37073435016976 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i | RAND(3) |
+-----+-----+
```

```

+----+-----+
| i   | RAND(3) |
+----+-----+
| 1   | 0.90576975597606 |
| 2   | 0.37307905813035 |
| 3   | 0.14808605345719 |
+----+-----+
3 rows in set (0.01 sec)

```

`RAND()` in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join). Thus, for optimizer purposes, `RAND()` is not a constant value and cannot be used for index optimizations. For more information, see [Section 8.2.1.14, “Function Call Optimization”](#).

Use of a column with `RAND()` values in an `ORDER BY` or `GROUP BY` clause may yield unexpected results because for either clause a `RAND()` expression can be evaluated multiple times for the same row, each time returning a different result. If the goal is to retrieve rows in random order, you can use a statement like this:

```
SELECT * FROM tbl_name ORDER BY RAND();
```

To select a random sample from a set of rows, combine `ORDER BY RAND()` with `LIMIT`:

```
SELECT * FROM table1, table2 WHERE a=b AND c<d ORDER BY RAND() LIMIT 1000;
```

`RAND()` is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `ROUND(X)`, `ROUND(X,D)`

Rounds the argument `X` to `D` decimal places. The rounding algorithm depends on the data type of `X`. `D` defaults to 0 if not specified. `D` can be negative to cause `D` digits left of the decimal point of the value `X` to become zero.

```

mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20

```

The return value has the same type as the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```

mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+-----+-----+
| ROUND(150.000,2) | ROUND(150,2) |
+-----+-----+
| 150.00 | 150 |
+-----+-----+

```

`ROUND()` uses the following rules depending on the type of the first argument:

- For exact-value numbers, `ROUND()` uses the “round half away from zero” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A

value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For more information, see [Section 12.19, “Precision Math”](#).

- `SIGN(X)`

Returns the sign of the argument as `-1`, `0`, or `1`, depending on whether `X` is negative, zero, or positive.

```
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

- `SIN(X)`

Returns the sine of `X`, where `X` is given in radians.

```
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

- `SQRT(X)`

Returns the square root of a nonnegative number `X`.

```
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
mysql> SELECT SQRT(-16);
-> NULL
```

- `TAN(X)`

Returns the tangent of `X`, where `X` is given in radians.

```
mysql> SELECT TAN(PI());
-> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
-> 1.5574077246549
```

- `TRUNCATE(X,D)`

Returns the number `X`, truncated to `D` decimal places. If `D` is `0`, the result has no decimal point or fractional part. `D` can be negative to cause `D` digits left of the decimal point of the value `X` to become zero.

```
mysql> SELECT TRUNCATE(1.223,1);
-> 1.2
mysql> SELECT TRUNCATE(1.999,1);
```

```

-> 1.9
mysql> SELECT TRUNCATE(1.999,0);
-> 1
mysql> SELECT TRUNCATE(-1.999,1);
-> -1.9
mysql> SELECT TRUNCATE(122,-2);
-> 100
mysql> SELECT TRUNCATE(10.28*100,0);
-> 1028

```

All numbers are rounded toward zero.

12.6 Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See [Section 11.2, “Date and Time Data Types”](#), for a description of the range of values each date and time type has and the valid formats in which values may be specified.

Table 12.10 Date and Time Functions

| Name | Description |
|--|--|
| ADDDATE () | Add time values (intervals) to a date value |
| ADDTIME () | Add time |
| CONVERT_TZ () | Convert from one time zone to another |
| CURDATE () | Return the current date |
| CURRENT_DATE (), CURRENT_DATE | Synonyms for CURDATE() |
| CURRENT_TIME (), CURRENT_TIME | Synonyms for CURTIME() |
| CURRENT_TIMESTAMP (), CURRENT_TIMESTAMP | Synonyms for NOW() |
| CURTIME () | Return the current time |
| DATE () | Extract the date part of a date or datetime expression |
| DATE_ADD () | Add time values (intervals) to a date value |
| DATE_FORMAT () | Format date as specified |
| DATE_SUB () | Subtract a time value (interval) from a date |
| DATEDIFF () | Subtract two dates |
| DAY () | Synonym for DAYOFMONTH() |
| DAYNAME () | Return the name of the weekday |
| DAYOFMONTH () | Return the day of the month (0-31) |
| DAYOFWEEK () | Return the weekday index of the argument |
| DAYOFYEAR () | Return the day of the year (1-366) |
| EXTRACT () | Extract part of a date |
| FROM_DAYS () | Convert a day number to a date |
| FROM_UNIXTIME () | Format Unix timestamp as a date |
| GET_FORMAT () | Return a date format string |
| HOUR () | Extract the hour |
| LAST_DAY | Return the last day of the month for the argument |
| LOCALTIME (), LOCALTIME | Synonym for NOW() |
| LOCALTIMESTAMP, LOCALTIMESTAMP () | Synonym for NOW() |
| MAKEDATE () | Create a date from the year and day of year |

| Name | Description |
|--------------------|---|
| MAKETIME () | Create time from hour, minute, second |
| MICROSECOND () | Return the microseconds from argument |
| MINUTE () | Return the minute from the argument |
| MONTH () | Return the month from the date passed |
| MONTHNAME () | Return the name of the month |
| NOW () | Return the current date and time |
| PERIOD_ADD () | Add a period to a year-month |
| PERIOD_DIFF () | Return the number of months between periods |
| QUARTER () | Return the quarter from a date argument |
| SEC_TO_TIME () | Converts seconds to 'hh:mm:ss' format |
| SECOND () | Return the second (0-59) |
| STR_TO_DATE () | Convert a string to a date |
| SUBDATE () | Synonym for DATE_SUB() when invoked with three arguments |
| SUBTIME () | Subtract times |
| SYSDATE () | Return the time at which the function executes |
| TIME () | Extract the time portion of the expression passed |
| TIME_FORMAT () | Format as time |
| TIME_TO_SEC () | Return the argument converted to seconds |
| TIMEDIFF () | Subtract time |
| TIMESTAMP () | With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments |
| TIMESTAMPADD () | Add an interval to a datetime expression |
| TIMESTAMPDIFF () | Subtract an interval from a datetime expression |
| TO_DAYS () | Return the date argument converted to days |
| TO_SECONDS () | Return the date or datetime argument converted to seconds since Year 0 |
| UNIX_TIMESTAMP () | Return a Unix timestamp |
| UTC_DATE () | Return the current UTC date |
| UTC_TIME () | Return the current UTC time |
| UTC_TIMESTAMP () | Return the current UTC date and time |
| WEEK () | Return the week number |
| WEEKDAY () | Return the weekday index |
| WEEKOFYEAR () | Return the calendar week of the date (1-53) |
| YEAR () | Return the year |
| YEARWEEK () | Return the year and week |

Here is an example that uses date functions. The following query selects all rows with a *date_col* value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
-> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW()` within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to `CURDATE()`, `CURTIME()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and to any of their synonyms.

The `CURRENT_TIMESTAMP()`, `CURRENT_TIME()`, `CURRENT_DATE()`, and `FROM_UNIXTIME()` functions return values in the current session time zone, which is available as the session value of the `time_zone` system variable. In addition, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the session time zone. See [Section 5.1.12, “MySQL Server Time Zone Support”](#).

Some date functions can be used with “zero” dates or incomplete dates such as `'2001-11-00'`, whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
      -> 0, 0
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00', INTERVAL 1 DAY);
      -> NULL
mysql> SELECT DAYNAME('2006-05-00');
      -> NULL
```

Note

From MySQL 5.5.16 to 5.5.20, a change in handling of a date-related assertion caused several functions to become more strict when passed a `DATE()` function value as their argument and reject incomplete dates with a day part of zero. These functions are affected: `CONVERT_TZ()`, `DATE_ADD()`, `DATE_SUB()`, `DAYOFYEAR()`, `LAST_DAY()`, `TIMESTAMPDIFF()`, `TO_DAYS()`, `TO_SECONDS()`, `WEEK()`, `WEEKDAY()`, `WEEKOFYEAR()`, `YEARWEEK()`. Because this changes date-handling behavior in General Availability-status series MySQL 5.5, the change was reverted in 5.5.21.

- `ADDDATE(date, INTERVAL expr unit), ADDDATE(expr, days)`

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see [Temporal Intervals](#).

```
mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
      -> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
      -> '2008-02-02'
```

When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`.

```
mysql> SELECT ADDDATE('2008-01-02', 31);
      -> '2008-02-02'
```

- `ADDTIME(expr1, expr2)`

`ADDTIME()` adds `expr2` to `expr1` and returns the result. `expr1` is a time or datetime expression, and `expr2` is a time expression.

```
mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
```

```
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'
```

- `CONVERT_TZ(dt, from_tz, to_tz)`

`CONVERT_TZ()` converts a datetime value *dt* from the time zone given by *from_tz* to the time zone given by *to_tz* and returns the resulting value. Time zones are specified as described in [Section 5.1.12, “MySQL Server Time Zone Support”](#). This function returns `NULL` if the arguments are invalid.

If the value falls out of the supported range of the `TIMESTAMP` type when converted from *from_tz* to UTC, no conversion occurs. The `TIMESTAMP` range is described in [Section 11.2.1, “Date and Time Data Type Syntax”](#).

```
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', 'GMT', 'MET');
-> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', '+00:00', '+10:00');
-> '2004-01-01 22:00:00'
```

Note

To use named time zones such as `'MET'` or `'Europe/Amsterdam'`, the time zone tables must be properly set up. For instructions, see [Section 5.1.12, “MySQL Server Time Zone Support”](#).

- `CURDATE()`

Returns the current date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in string or numeric context.

```
mysql> SELECT CURDATE();
-> '2008-06-13'
mysql> SELECT CURDATE() + 0;
-> 20080613
```

- `CURRENT_DATE, CURRENT_DATE()`

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms for `CURDATE()`.

- `CURRENT_TIME, CURRENT_TIME()`

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()`.

- `CURRENT_TIMESTAMP, CURRENT_TIMESTAMP()`

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()`.

- `CURTIME()`

Returns the current time as a value in `'hh:mm:ss'` or `hhmmss` format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.

```
mysql> SELECT CURTIME();
-> '23:50:26'
mysql> SELECT CURTIME() + 0;
-> 235026.000000
```

- `DATE(expr)`

Extracts the date part of the date or datetime expression *expr*.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

- `DATEDIFF(expr1, expr2)`

`DATEDIFF()` returns $expr1 - expr2$ expressed as a value in days from one date to the other. $expr1$ and $expr2$ are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
-> -31
```

- `DATE_ADD(date,INTERVAL expr unit)`, `DATE_SUB(date,INTERVAL expr unit)`

These functions perform date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is evaluated as a string; it may start with a `-` for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted.

For more information about temporal interval syntax, including a full list of *unit* specifiers, the expected form of the *expr* argument for each *unit* value, and rules for operand interpretation in temporal arithmetic, see [Temporal Intervals](#).

The return value depends on the arguments:

- `DATE` if the *date* argument is a `DATE` value and your calculations involve only `YEAR`, `MONTH`, and `DAY` parts (that is, no time parts).
- `DATETIME` if the first argument is a `DATETIME` (or `TIMESTAMP`) value, or if the first argument is a `DATE` and the *unit* value uses `HOURS`, `MINUTES`, or `SECONDS`.
- String otherwise.

To ensure that the result is `DATETIME`, you can use `CAST()` to convert the first argument to `DATETIME`.

```
mysql> SELECT DATE_ADD('2018-05-01',INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01',INTERVAL 1 YEAR);
-> '2017-05-01'
mysql> SELECT DATE_ADD('2020-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '2021-01-01 00:00:00'
mysql> SELECT DATE_ADD('2018-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '2019-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00',
-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1899-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
-> INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

- `DATE_FORMAT(date, format)`

Formats the *date* value according to the *format* string.

The specifiers shown in the following table may be used in the *format* string. The `%` character is required before format specifier characters. The specifiers apply to other functions as well: `STR_TO_DATE()`, `TIME_FORMAT()`, `UNIX_TIMESTAMP()`.

| Specifier | Description |
|-----------------|---|
| <code>%a</code> | Abbreviated weekday name (Sun..Sat) |
| <code>%b</code> | Abbreviated month name (Jan..Dec) |
| <code>%c</code> | Month, numeric (0..12) |
| <code>%D</code> | Day of the month with English suffix (0th, 1st, 2nd, 3rd, ...) |
| <code>%d</code> | Day of the month, numeric (00..31) |
| <code>%e</code> | Day of the month, numeric (0..31) |
| <code>%f</code> | Microseconds (000000..999999) |
| <code>%H</code> | Hour (00..23) |
| <code>%h</code> | Hour (01..12) |
| <code>%I</code> | Hour (01..12) |
| <code>%i</code> | Minutes, numeric (00..59) |
| <code>%j</code> | Day of year (001..366) |
| <code>%k</code> | Hour (0..23) |
| <code>%l</code> | Hour (1..12) |
| <code>%M</code> | Month name (January..December) |
| <code>%m</code> | Month, numeric (00..12) |
| <code>%p</code> | AM or PM |
| <code>%r</code> | Time, 12-hour (hh:mm:ss followed by AM or PM) |
| <code>%S</code> | Seconds (00..59) |
| <code>%s</code> | Seconds (00..59) |
| <code>%T</code> | Time, 24-hour (hh:mm:ss) |
| <code>%U</code> | Week (00..53), where Sunday is the first day of the week; <code>WEEK()</code> mode 0 |
| <code>%u</code> | Week (00..53), where Monday is the first day of the week; <code>WEEK()</code> mode 1 |
| <code>%V</code> | Week (01..53), where Sunday is the first day of the week; <code>WEEK()</code> mode 2; used with <code>%X</code> |
| <code>%v</code> | Week (01..53), where Monday is the first day of the week; <code>WEEK()</code> mode 3; used with <code>%x</code> |
| <code>%W</code> | Weekday name (Sunday..Saturday) |
| <code>%w</code> | Day of the week (0=Sunday..6=Saturday) |
| <code>%X</code> | Year for the week where Sunday is the first day of the week, numeric, four digits; used with <code>%V</code> |
| <code>%x</code> | Year for the week, where Monday is the first day of the week, numeric, four digits; used with <code>%v</code> |
| <code>%Y</code> | Year, numeric, four digits |
| <code>%y</code> | Year, numeric (two digits) |

| Specifier | Description |
|-----------------|--|
| <code>%%</code> | A literal <code>%</code> character |
| <code>%x</code> | <code>x</code> , for any “ <code>x</code> ” not listed above |

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as `'2014-00-00'`.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable (Section 10.16, “MySQL Server Locale Support”).

For the `%U`, `%u`, `%V`, and `%v` specifiers, see the description of the `WEEK()` function for information about the mode values. The mode affects how week numbering occurs.

`DATE_FORMAT()` returns a string with a character set and collation given by `character_set_connection` and `collation_connection` so that it can return month and weekday names containing non-ASCII characters.

```
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00',
->          '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
->          '%H %k %I %r %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- `DATE_SUB(date, INTERVAL expr unit)`

See the description for `DATE_ADD()`.

- `DAY(date)`

`DAY()` is a synonym for `DAYOFMONTH()`.

- `DAYNAME(date)`

Returns the name of the weekday for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.16, “MySQL Server Locale Support”).

```
mysql> SELECT DAYNAME('2007-02-03');
-> 'Saturday'
```

- `DAYOFMONTH(date)`

Returns the day of the month for `date`, in the range 1 to 31, or 0 for dates such as `'0000-00-00'` or `'2008-00-00'` that have a zero day part.

```
mysql> SELECT DAYOFMONTH('2007-02-03');
-> 3
```

- `DAYOFWEEK(date)`

Returns the weekday index for `date` (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```

- `DAYOFYEAR(date)`

Returns the day of the year for *date*, in the range 1 to 366.

```
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

- `EXTRACT(unit FROM date)`

The `EXTRACT()` function uses the same kinds of *unit* specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic. For information on the *unit* argument, see [Temporal Intervals](#).

```
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2019-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND
-> FROM '2003-01-02 10:30:00.000123');
-> 123
```

- `FROM_DAYS(N)`

Given a day number *N*, returns a `DATE` value.

```
mysql> SELECT FROM_DAYS(730669);
-> '2000-07-03'
```

Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See [Section 12.8, “What Calendar Is Used By MySQL?”](#).

- `FROM_UNIXTIME(unix_timestamp [, format])`

Returns a representation of the *unix_timestamp* argument as a value in '`YYYY-MM-DD hh:mm:ss`' or '`YYYYMMDDhhmmss`' format, depending on whether the function is used in string or numeric context. *unix_timestamp* is an internal timestamp value representing seconds since '`1970-01-01 00:00:00`' UTC, such as produced by the `UNIX_TIMESTAMP()` function.

The return value is expressed in the session time zone. (Clients can set the session time zone as described in [Section 5.1.12, “MySQL Server Time Zone Support”](#).) The *format* string, if given, is used to format the result the same way as described in the entry for the `DATE_FORMAT()` function.

```
mysql> SELECT FROM_UNIXTIME(1447430881);
-> '2015-11-13 10:08:01'
mysql> SELECT FROM_UNIXTIME(1447430881) + 0;
-> 20151113100801
mysql> SELECT FROM_UNIXTIME(1447430881,
-> '%Y %D %M %h:%i:%s %x');
-> '2015 13th November 10:08:01 2015'
```

Note

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.

- `GET_FORMAT({DATE|TIME|DATETIME}, { 'EUR' | 'USA' | 'JIS' | 'ISO' | 'INTERNAL' })`

Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and the `STR_TO_DATE()` functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT()` function description). ISO format refers to ISO 9075, not ISO 8601.

| Function Call | Result |
|---|----------------------------------|
| <code>GET_FORMAT(DATE, 'USA')</code> | <code>'%m.%d.%Y'</code> |
| <code>GET_FORMAT(DATE, 'JIS')</code> | <code>'%Y-%m-%d'</code> |
| <code>GET_FORMAT(DATE, 'ISO')</code> | <code>'%Y-%m-%d'</code> |
| <code>GET_FORMAT(DATE, 'EUR')</code> | <code>'%d.%m.%Y'</code> |
| <code>GET_FORMAT(DATE, 'INTERNAL')</code> | <code>'%Y%m%d'</code> |
| <code>GET_FORMAT(DATETIME, 'USA')</code> | <code>'%Y-%m-%d %H.%i.%s'</code> |
| <code>GET_FORMAT(DATETIME, 'JIS')</code> | <code>'%Y-%m-%d %H:%i:%s'</code> |
| <code>GET_FORMAT(DATETIME, 'ISO')</code> | <code>'%Y-%m-%d %H:%i:%s'</code> |
| <code>GET_FORMAT(DATETIME, 'EUR')</code> | <code>'%Y-%m-%d %H.%i.%s'</code> |
| <code>GET_FORMAT(DATETIME, 'INTERNAL')</code> | <code>'%Y%m%d%H%i%s'</code> |
| <code>GET_FORMAT(TIME, 'USA')</code> | <code>'%h:%i:%s %p'</code> |
| <code>GET_FORMAT(TIME, 'JIS')</code> | <code>'%H:%i:%s'</code> |
| <code>GET_FORMAT(TIME, 'ISO')</code> | <code>'%H:%i:%s'</code> |
| <code>GET_FORMAT(TIME, 'EUR')</code> | <code>'%H.%i.%s'</code> |
| <code>GET_FORMAT(TIME, 'INTERNAL')</code> | <code>'%H%i%s'</code> |

`TIMESTAMP` can also be used as the first argument to `GET_FORMAT()`, in which case the function returns the same values as for `DATETIME`.

```
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
-> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'
```

- `HOUR(time)`

Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so `HOUR` can return values greater than 23.

```
mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272
```

- `LAST_DAY(date)`

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns `NULL` if the argument is invalid.

```
mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL
```

- `LOCALTIME`, `LOCALTIME()`

`LOCALTIME` and `LOCALTIME()` are synonyms for `NOW()`.

- `LOCALTIMESTAMP`, `LOCALTIMESTAMP()`

`LOCALTIMESTAMP` and `LOCALTIMESTAMP()` are synonyms for `NOW()`.

- `MAKEDATE`(*year*, *dayofyear*)

Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is `NULL`.

```
mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
-> '2011-01-31', '2011-02-01'
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
-> '2011-12-31', '2014-12-31'
mysql> SELECT MAKEDATE(2011,0);
-> NULL
```

- `MAKETIME`(*hour*, *minute*, *second*)

Returns a time value calculated from the *hour*, *minute*, and *second* arguments.

```
mysql> SELECT MAKETIME(12,15,30);
-> '12:15:30'
```

- `MICROSECOND`(*expr*)

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

```
mysql> SELECT MICROSECOND('12:00:00.123456');
-> 123456
mysql> SELECT MICROSECOND('2019-12-31 23:59:59.000010');
-> 10
```

- `MINUTE`(*time*)

Returns the minute for *time*, in the range 0 to 59.

```
mysql> SELECT MINUTE('2008-02-03 10:05:03');
-> 5
```

- `MONTH`(*date*)

Returns the month for *date*, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

```
mysql> SELECT MONTH('2008-02-03');
-> 2
```

- `MONTHNAME`(*date*)

Returns the full name of the month for *date*. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.16, "MySQL Server Locale Support").

```
mysql> SELECT MONTHNAME('2008-02-03');
-> 'February'
```

- `NOW()`

Returns the current date and time as a value in '`YYYY-MM-DD hh:mm:ss`' or `YYYYMMDDhhmmss` format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.

```
mysql> SELECT NOW();
```

```

-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000

```

`NOW()` returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.) This differs from the behavior for `SYSDATE()`, which returns the exact time at which it executes.

```

mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW()          | SLEEP(2) | NOW()          |
+-----+-----+-----+
| 2006-04-12 13:47:36 |          0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()      | SLEEP(2) | SYSDATE()      |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+

```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. Setting the timestamp to a nonzero value causes each subsequent invocation of `NOW()` to return that value. Setting the timestamp to zero cancels this effect so that `NOW()` once again returns the current date and time.

See the description for `SYSDATE()` for additional information about the differences between the two functions.

- `PERIOD_ADD(P,N)`

Adds `N` months to period `P` (in the format `YYMM` or `YYYYMM`). Returns a value in the format `YYYYMM`. Note that the period argument `P` is *not* a date value.

```

mysql> SELECT PERIOD_ADD(200801,2);
-> 200803

```

- `PERIOD_DIFF(P1,P2)`

Returns the number of months between periods `P1` and `P2`. `P1` and `P2` should be in the format `YYMM` or `YYYYMM`. Note that the period arguments `P1` and `P2` are *not* date values.

```

mysql> SELECT PERIOD_DIFF(200802,200703);
-> 11

```

- `QUARTER(date)`

Returns the quarter of the year for `date`, in the range 1 to 4.

```

mysql> SELECT QUARTER('2008-04-01');
-> 2

```

- `SECOND(time)`

Returns the second for `time`, in the range 0 to 59.

```

mysql> SELECT SECOND('10:05:03');
-> 3

```

- `SEC_TO_TIME(seconds)`

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

```
mysql> SELECT SEC_TO_TIME(2378);
-> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
-> 3938
```

- `STR_TO_DATE(str,format)`

This is the inverse of the `DATE_FORMAT()` function. It takes a string *str* and a format string *format*. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If the date, time, or datetime value extracted from *str* is illegal, `STR_TO_DATE()` returns `NULL` and produces a warning.

The server scans *str* attempting to match *format* to it. The format string can contain literal characters and format specifiers beginning with `%`. Literal characters in *format* must match literally in *str*. Format specifiers in *format* must match a date or time part in *str*. For the specifiers that can be used in *format*, see the `DATE_FORMAT()` function description.

```
mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
-> '2013-05-01'
mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
-> '2013-05-01'
```

Scanning starts at the beginning of *str* and fails if *format* is found not to match. Extra characters at the end of *str* are ignored.

```
mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
-> '09:30:17'
mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
-> NULL
mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
-> '09:30:17'
```

Unspecified date or time parts have a value of 0, so incompletely specified values in *str* produce a result with some or all parts set to 0:

```
mysql> SELECT STR_TO_DATE('abc','abc');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('9','%m');
-> '0000-09-00'
mysql> SELECT STR_TO_DATE('9','%s');
-> '00:00:09'
```

Range checking on the parts of date values is as described in [Section 11.2.2, “The DATE, DATETIME, and TIMESTAMP Types”](#). This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.

```
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004', '%m/%d/%Y');
-> '2004-04-31'
```

If the `NO_ZERO_DATE` or `NO_ZERO_IN_DATE` SQL mode is enabled, zero dates or part of dates are disallowed. In that case, `STR_TO_DATE()` returns `NULL` and generates a warning:

```
mysql> SET sql_mode = '';
mysql> SELECT STR_TO_DATE('15:35:00', '%H:%i:%s');
+-----+
| STR_TO_DATE('15:35:00', '%H:%i:%s') |
+-----+
```

```

| 15:35:00 |
+-----+
mysql> SET sql_mode = 'NO_ZERO_IN_DATE';
mysql> SELECT STR_TO_DATE('15:35:00', '%h:%i:%s');
+-----+
| STR_TO_DATE('15:35:00', '%h:%i:%s') |
+-----+
| NULL |
+-----+
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1411
Message: Incorrect datetime value: '15:35:00' for function str_to_date

```

Note

You cannot use format `"%X%V"` to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```

mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'

```

- `SUBDATE(date, INTERVAL expr unit), SUBDATE(expr, days)`

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```

mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'

```

The second form enables the use of an integer value for `days`. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression `expr`.

```

mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'

```

- `SUBTIME(expr1, expr2)`

`SUBTIME()` returns `expr1 - expr2` expressed as a value in the same format as `expr1`. `expr1` is a time or datetime expression, and `expr2` is a time expression.

```

mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2007-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
-> '-00:59:59.999999'

```

- `SYSDATE()`

Returns the current date and time as a value in `'YYYY-MM-DD hh:mm:ss'` or `YYYYMMDDhhmmss` format, depending on whether the function is used in string or numeric context.

`SYSDATE()` returns the time at which it executes. This differs from the behavior for `NOW()`, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.)

```

mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2006-04-12 13:47:36 | 0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

```

```

+-----+-----+-----+
mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()          | SLEEP(2) | SYSDATE()          |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+

```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET TIMESTAMP`, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

Alternatively, you can use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This works if the option is used on both the master and the slave.

The nondeterministic nature of `SYSDATE()` also means that indexes cannot be used for evaluating expressions that refer to it.

- `TIME(expr)`

Extracts the time part of the time or datetime expression `expr` and returns it as a string.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```

mysql> SELECT TIME('2003-12-31 01:02:03');
-> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
-> '01:02:03.000123'

```

- `TIMEDIFF(expr1,expr2)`

`TIMEDIFF()` returns `expr1 - expr2` expressed as a time value. `expr1` and `expr2` are time or date-and-time expressions, but both must be of the same type.

The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()`, both of which return integers.

```

mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
-> '2000:01:01 00:00:00.000001');
-> '-00:00:00.000001'
mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001',
-> '2008-12-30 01:01:01.000002');
-> '46:58:57.999999'

```

- `TIMESTAMP(expr)`, `TIMESTAMP(expr1,expr2)`

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

```

mysql> SELECT TIMESTAMP('2003-12-31');
-> '2003-12-31 00:00:00'
mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
-> '2004-01-01 00:00:00'

```

- `TIMESTAMPADD(unit, interval, datetime_expr)`

Adds the integer expression *interval* to the date or datetime expression *datetime_expr*. The unit for *interval* is given by the *unit* argument, which should be one of the following values: `MICROSECOND` (microseconds), `SECOND`, `MINUTE`, `HOURL`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

The *unit* value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

```
mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
-> '2003-01-02 00:01:00'
mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
-> '2003-01-09'
```

- `TIMESTAMPDIFF(unit, datetime_expr1, datetime_expr2)`

Returns *datetime_expr2* - *datetime_expr1*, where *datetime_expr1* and *datetime_expr2* are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the *unit* argument. The legal values for *unit* are the same as those listed in the description of the `TIMESTAMPADD()` function.

```
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
-> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
-> -1
mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
-> 128885
```

Note

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.

- `TIME_FORMAT(time, format)`

This is used like the `DATE_FORMAT()` function, but the *format* string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` value or `0`.

If the *time* value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

- `TIME_TO_SEC(time)`

Returns the *time* argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- `TO_DAYS(date)`

Given a date *date*, returns a day number (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
```

```
-> 733321
```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 12.8, “What Calendar Is Used By MySQL?”](#), for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in [Section 11.2, “Date and Time Data Types”](#). For example, `'2008-10-07'` and `'08-10-07'` are seen as identical dates:

```
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
-> 733687, 733687
```

In MySQL, the zero date is defined as `'0000-00-00'`, even though this date is itself considered invalid. This means that, for `'0000-00-00'` and `'0000-01-01'`, `TO_DAYS()` returns the values shown here:

```
mysql> SELECT TO_DAYS('0000-00-00');
+-----+
| to_days('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_DAYS('0000-01-01');
+-----+
| to_days('0000-01-01') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `TO_SECONDS(expr)`

Given a date or datetime *expr*, returns the number of seconds since the year 0. If *expr* is not a valid date or datetime value, returns `NULL`.

```
mysql> SELECT TO_SECONDS(950501);
-> 62966505600
mysql> SELECT TO_SECONDS('2009-11-29');
-> 63426672000
mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
-> 63426721412
mysql> SELECT TO_SECONDS(NOW());
-> 63426721458
```

Like `TO_DAYS()`, `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 12.8, “What Calendar Is Used By MySQL?”](#), for details.

Like `TO_DAYS()`, `TO_SECONDS()`, converts two-digit year values in dates to four-digit form using the rules in [Section 11.2, “Date and Time Data Types”](#).

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', `TO_SECONDS()` returns the values shown here:

```
mysql> SELECT TO_SECONDS('0000-00-00');
+-----+
| TO_SECONDS('0000-00-00') |
+-----+
|                          NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_SECONDS('0000-01-01');
+-----+
| TO_SECONDS('0000-01-01') |
+-----+
|                          86400 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `UNIX_TIMESTAMP([date])`

If `UNIX_TIMESTAMP()` is called with no *date* argument, it returns a Unix timestamp representing seconds since '1970-01-01 00:00:00' UTC.

If `UNIX_TIMESTAMP()` is called with a *date* argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. The server interprets *date* as a value in the session time zone and converts it to an internal Unix timestamp value in UTC. (Clients can set the session time zone as described in [Section 5.1.12, “MySQL Server Time Zone Support”](#).) The *date* argument may be a `DATE`, `DATETIME`, or `TIMESTAMP` string, or a number in `YYMMDD`, `YYMMDDhhmmss`, `YYYYMMDD`, or `YYYYMMDDhhmmss` format.

The return value is an unsigned integer.

When the *date* argument is a `TIMESTAMP` column, `UNIX_TIMESTAMP()` returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion.

The valid range of argument values is the same as for the `TIMESTAMP` data type: '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns 0.

```
mysql> SELECT UNIX_TIMESTAMP();
-> 1447431666
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
-> 1447431619
```

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes such as Daylight Saving Time (DST), it is possible for `UNIX_TIMESTAMP()` to map two values that are distinct in a non-UTC time zone to the same Unix timestamp value. `FROM_UNIXTIME()` will map that value back to only one of the original values. Here is an example, using values that are distinct in the `MET` time zone:

```
mysql> SET time_zone = 'MET';
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT FROM_UNIXTIME(1111885200);
+-----+
| FROM_UNIXTIME(1111885200) |
+-----+
| 2005-03-27 03:00:00 |
+-----+
```

**Note**

To use named time zones such as 'MET' or 'Europe/Amsterdam', the time zone tables must be properly set up. For instructions, see [Section 5.1.12, “MySQL Server Time Zone Support”](#).

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast them to signed integers. See [Section 12.10, “Cast Functions and Operators”](#).

- `UTC_DATE`, `UTC_DATE()`

Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in string or numeric context.

```
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

- `UTC_TIME`, `UTC_TIME()`

Returns the current UTC time as a value in 'hh:mm:ss' or hhmmss format, depending on whether the function is used in string or numeric context.

```
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000
```

- `UTC_TIMESTAMP`, `UTC_TIMESTAMP()`

Returns the current UTC date and time as a value in 'YYYY-MM-DD hh:mm:ss' or YYYYMMDDhhmmss format, depending on whether the function is used in string or numeric context.

```
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804.000000
```

- `WEEK(date[,mode])`

This function returns the week number for *date*. The two-argument form of `WEEK()` enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the *mode* argument is omitted, the value of the `default_week_format` system variable is used. See [Section 5.1.7, “Server System Variables”](#).

The following table describes how the *mode* argument works.

| Mode | First day of week | Range | Week 1 is the first week ... |
|------|-------------------|-------|------------------------------|
| 0 | Sunday | 0-53 | with a Sunday in this year |

| Mode | First day of week | Range | Week 1 is the first week ... |
|------|-------------------|-------|-------------------------------|
| 1 | Monday | 0-53 | with 4 or more days this year |
| 2 | Sunday | 1-53 | with a Sunday in this year |
| 3 | Monday | 1-53 | with 4 or more days this year |
| 4 | Sunday | 0-53 | with 4 or more days this year |
| 5 | Monday | 0-53 | with a Monday in this year |
| 6 | Sunday | 1-53 | with 4 or more days this year |
| 7 | Monday | 1-53 | with a Monday in this year |

For *mode* values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

- If the week containing January 1 has 4 or more days in the new year, it is week 1.
- Otherwise, it is the last week of the previous year, and the next week is week 1.

```
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
-> 53
```

If a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that `WEEK()` should return 52 because the given date actually occurs in the 52nd week of 1999. `WEEK()` returns 0 instead so that the return value is “the week number in the given year.” This makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional *mode* argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- `WEEKDAY(date)`

Returns the weekday index for *date* (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
```

- `WEEKOFYEAR(date)`

Returns the calendar week of the date as a number in the range from 1 to 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date, 3)`.

```
mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8
```

- `YEAR(date)`

Returns the year for *date*, in the range 1000 to 9999, or 0 for the “zero” date.

```
mysql> SELECT YEAR('1987-01-01');
-> 1987
```

- `YEARWEEK(date)`, `YEARWEEK(date,mode)`

Returns year and week for a date. The year in the result may be different from the year in the date argument for the first and the last week of the year.

The *mode* argument works exactly like the *mode* argument to `WEEK()`. For the single-argument syntax, a *mode* value of 0 is used. Unlike `WEEK()`, the value of `default_week_format` does not influence `YEARWEEK()`.

```
mysql> SELECT YEARWEEK('1987-01-01');
-> 198652
```

The week number is different from what the `WEEK()` function would return (0) for optional arguments 0 or 1, as `WEEK()` then returns the week in the context of the given year.

12.7 String Functions and Operators

Table 12.11 String Functions and Operators

| Name | Description |
|---------------------------------|--|
| <code>ASCII()</code> | Return numeric value of left-most character |
| <code>BIN()</code> | Return a string containing binary representation of a number |
| <code>BIT_LENGTH()</code> | Return length of argument in bits |
| <code>CHAR()</code> | Return the character for each integer passed |
| <code>CHAR_LENGTH()</code> | Return number of characters in argument |
| <code>CHARACTER_LENGTH()</code> | Synonym for <code>CHAR_LENGTH()</code> |
| <code>CONCAT()</code> | Return concatenated string |
| <code>CONCAT_WS()</code> | Return concatenate with separator |
| <code>ELT()</code> | Return string at index number |
| <code>EXPORT_SET()</code> | Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string |
| <code>FIELD()</code> | Index (position) of first argument in subsequent arguments |
| <code>FIND_IN_SET()</code> | Index (position) of first argument within second argument |
| <code>FORMAT()</code> | Return a number formatted to specified number of decimal places |
| <code>HEX()</code> | Hexadecimal representation of decimal or string value |
| <code>INSERT()</code> | Insert substring at specified position up to specified number of characters |
| <code>INSTR()</code> | Return the index of the first occurrence of substring |
| <code>LCASE()</code> | Synonym for <code>LOWER()</code> |
| <code>LEFT()</code> | Return the leftmost number of characters as specified |
| <code>LENGTH()</code> | Return the length of a string in bytes |

| Name | Description |
|---------------------|--|
| LIKE | Simple pattern matching |
| LOAD_FILE () | Load the named file |
| LOCATE () | Return the position of the first occurrence of substring |
| LOWER () | Return the argument in lowercase |
| LPAD () | Return the string argument, left-padded with the specified string |
| LTRIM () | Remove leading spaces |
| MAKE_SET () | Return a set of comma-separated strings that have the corresponding bit in bits set |
| MATCH | Perform full-text search |
| MID () | Return a substring starting from the specified position |
| NOT LIKE | Negation of simple pattern matching |
| NOT REGEXP | Negation of REGEXP |
| OCT () | Return a string containing octal representation of a number |
| OCTET_LENGTH () | Synonym for LENGTH() |
| ORD () | Return character code for leftmost character of the argument |
| POSITION () | Synonym for LOCATE() |
| QUOTE () | Escape the argument for use in an SQL statement |
| REGEXP | Whether string matches regular expression |
| REPEAT () | Repeat a string the specified number of times |
| REPLACE () | Replace occurrences of a specified string |
| REVERSE () | Reverse the characters in a string |
| RIGHT () | Return the specified rightmost number of characters |
| RLIKE | Whether string matches regular expression |
| RPAD () | Append string the specified number of times |
| RTRIM () | Remove trailing spaces |
| SOUNDEX () | Return a soundex string |
| SOUNDS LIKE | Compare sounds |
| SPACE () | Return a string of the specified number of spaces |
| STRCMP () | Compare two strings |
| SUBSTR () | Return the substring as specified |
| SUBSTRING () | Return the substring as specified |
| SUBSTRING_INDEX () | Return a substring from a string before the specified number of occurrences of the delimiter |
| TRIM () | Remove leading and trailing spaces |
| UCASE () | Synonym for UPPER() |
| UNHEX () | Return a string containing hex representation of a number |
| UPPER () | Convert to uppercase |

String-valued functions return `NULL` if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See [Section 5.1.1, “Configuring the Server”](#).

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- `ASCII(str)`

Returns the numeric value of the leftmost character of the string `str`. Returns 0 if `str` is the empty string. Returns `NULL` if `str` is `NULL`. `ASCII()` works for 8-bit characters.

```
mysql> SELECT ASCII('2');
      -> 50
mysql> SELECT ASCII(2);
      -> 50
mysql> SELECT ASCII('dx');
      -> 100
```

See also the `ORD()` function.

- `BIN(N)`

Returns a string representation of the binary value of `N`, where `N` is a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,2)`. Returns `NULL` if `N` is `NULL`.

```
mysql> SELECT BIN(12);
      -> '1100'
```

- `BIT_LENGTH(str)`

Returns the length of the string `str` in bits.

```
mysql> SELECT BIT_LENGTH('text');
      -> 32
```

- `CHAR(N,... [USING charset_name])`

`CHAR()` interprets each argument `N` as an integer and returns a string consisting of the characters given by the code values of those integers. `NULL` values are skipped.

```
mysql> SELECT CHAR(77,121,83,81,'76');
      -> 'MySQL'
mysql> SELECT CHAR(77,77.3,'77.3');
      -> 'MMM'
```

`CHAR()` arguments larger than 255 are converted into multiple result bytes. For example, `CHAR(256)` is equivalent to `CHAR(1,0)`, and `CHAR(256*256)` is equivalent to `CHAR(1,0,0)`:

```
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+-----+-----+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+-----+-----+
| 0100          | 0100          |
+-----+-----+
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+-----+-----+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+-----+-----+
| 010000         | 010000         |
+-----+-----+
```

By default, `CHAR()` returns a binary string. To produce a string in a given character set, use the optional `USING` clause:

```
mysql> SELECT CHARSET(CHAR(X'65')), CHARSET(CHAR(X'65' USING utf8));
+-----+-----+
| CHARSET(CHAR(X'65')) | CHARSET(CHAR(X'65' USING utf8)) |
+-----+-----+
| binary              | utf8                          |
```

If `USING` is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` becomes `NULL`.

- `CHAR_LENGTH(str)`

Returns the length of the string `str`, measured in characters. A multibyte character counts as a single character. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

- `CHARACTER_LENGTH(str)`

`CHARACTER_LENGTH()` is a synonym for `CHAR_LENGTH()`.

- `CONCAT(str1, str2, ...)`

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent nonbinary string form.

`CONCAT()` returns `NULL` if any argument is `NULL`.

```
mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL
mysql> SELECT CONCAT(14.3);
-> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```
mysql> SELECT 'My' 'S' 'QL';
-> 'MySQL'
```

- `CONCAT_WS(separator, str1, str2, ...)`

`CONCAT_WS()` stands for Concatenate With Separator and is a special form of `CONCAT()`. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is `NULL`, the result is `NULL`.

```
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
-> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
-> 'First name,Last Name'
```

`CONCAT_WS()` does not skip empty strings. However, it does skip any `NULL` values after the separator argument.

- `ELT(N, str1, str2, str3, ...)`

`ELT()` returns the `N`th element of the list of strings: `str1` if `N = 1`, `str2` if `N = 2`, and so on. Returns `NULL` if `N` is less than 1 or greater than the number of arguments. `ELT()` is the complement of `FIELD()`.

```
mysql> SELECT ELT(1, 'Aa', 'Bb', 'Cc', 'Dd');
-> 'Aa'
mysql> SELECT ELT(4, 'Aa', 'Bb', 'Cc', 'Dd');
-> 'Dd'
```

- `EXPORT_SET(bits, on, off[, separator[, number_of_bits]])`

Returns a string such that for every bit set in the value *bits*, you get an *on* string and for every bit not set in the value, you get an *off* string. Bits in *bits* are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the *separator* string (the default being the comma character ,). The number of bits examined is given by *number_of_bits*, which has a default of 64 if not specified. *number_of_bits* is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of -1 is effectively the same as 64.

```
mysql> SELECT EXPORT_SET(5, 'Y', 'N', ',', '4');
-> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6, '1', '0', ',', '10');
-> '0,1,1,0,0,0,0,0,0,0'
```

- `FIELD(str, str1, str2, str3, ...)`

Returns the index (position) of *str* in the *str1, str2, str3, ...* list. Returns 0 if *str* is not found.

If all arguments to `FIELD()` are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If *str* is `NULL`, the return value is 0 because `NULL` fails equality comparison with any value. `FIELD()` is the complement of `ELT()`.

```
mysql> SELECT FIELD('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 2
mysql> SELECT FIELD('Gg', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 0
```

- `FIND_IN_SET(str, strlist)`

Returns a value in the range of 1 to *N* if the string *str* is in the string list *strlist* consisting of *N* substrings. A string list is a string composed of substrings separated by , characters. If the first argument is a constant string and the second is a column of type `SET`, the `FIND_IN_SET()` function is optimized to use bit arithmetic. Returns 0 if *str* is not in *strlist* or if *strlist* is the empty string. Returns `NULL` if either argument is `NULL`. This function does not work properly if the first argument contains a comma (,) character.

```
mysql> SELECT FIND_IN_SET('b', 'a,b,c,d');
-> 2
```

- `FORMAT(X, D[, locale])`

Formats the number *X* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. If *D* is 0, the result has no decimal point or fractional part.

The optional third parameter enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable (see [Section 10.16, "MySQL Server Locale Support"](#)). If no locale is specified, the default is 'en_US'.

```
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
mysql> SELECT FORMAT(12332.1, 4);
-> '12,332.1000'
mysql> SELECT FORMAT(12332.2, 0);
-> '12,332'
mysql> SELECT FORMAT(12332.2, 2, 'de_DE');
-> '12.332,20'
```

- `HEX(str)`, `HEX(N)`

For a string argument `str`, `HEX()` returns a hexadecimal string representation of `str` where each byte of each character in `str` is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the `UNHEX()` function.

For a numeric argument `N`, `HEX()` returns a hexadecimal string representation of the value of `N` treated as a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,16)`. The inverse of this operation is performed by `CONV(HEX(N),16,10)`.

```
mysql> SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
-> 'abc', 616263, 'abc'
mysql> SELECT HEX(255), CONV(HEX(255),16,10);
-> 'FF', 255
```

- `INSERT(str,pos,len,newstr)`

Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string. Replaces the rest of the string from position `pos` if `len` is not within the length of the rest of the string. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
-> 'QuWhattic'
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
-> 'Quadratic'
mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
-> 'QuWhat'
```

This function is multibyte safe.

- `INSTR(str,substr)`

Returns the position of the first occurrence of substring `substr` in string `str`. This is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

```
mysql> SELECT INSTR('foobarbar', 'bar');
-> 4
mysql> SELECT INSTR('xbar', 'foobar');
-> 0
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- `LCASE(str)`

`LCASE()` is a synonym for `LOWER()`.

- `LEFT(str,len)`

Returns the leftmost `len` characters from the string `str`, or `NULL` if any argument is `NULL`.

```
mysql> SELECT LEFT('foobarbar', 5);
-> 'fooba'
```

This function is multibyte safe.

- `LENGTH(str)`

Returns the length of the string `str`, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

```
mysql> SELECT LENGTH('text');
```

-> 4

**Note**

The `Length()` OpenGIS spatial function is named `GLength()` in MySQL.

- `LOAD_FILE(file_name)`

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the `FILE` privilege. The file must be readable by all and its size less than `max_allowed_packet` bytes. If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns `NULL`.

The `character_set_filesystem` system variable controls interpretation of file names that are given as literal strings.

```
mysql> UPDATE t
      SET blob_col=LOAD_FILE('/tmp/picture')
      WHERE id=1;
```

- `LOCATE(substr, str)`, `LOCATE(substr, str, pos)`

The first syntax returns the position of the first occurrence of substring `substr` in string `str`. The second syntax returns the position of the first occurrence of substring `substr` in string `str`, starting at position `pos`. Returns 0 if `substr` is not in `str`. Returns `NULL` if `substr` or `str` is `NULL`.

```
mysql> SELECT LOCATE('bar', 'foobarbar');
-> 4
mysql> SELECT LOCATE('xbar', 'foobar');
-> 0
mysql> SELECT LOCATE('bar', 'foobarbar', 5);
-> 7
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- `LOWER(str)`

Returns the string `str` with all characters changed to lowercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```
mysql> SELECT LOWER('QUADRATICALLY');
-> 'quadratically'
```

`LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-----+-----+
| New York   | new york                           |
+-----+-----+
```

This function is multibyte safe.

- `LPAD(str, len, padstr)`

Returns the string `str`, left-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```
mysql> SELECT LPAD('hi',4,'??');
-> '??hi'
mysql> SELECT LPAD('hi',1,'??');
-> 'h'
```

- `LTRIM(str)`

Returns the string *str* with leading space characters removed.

```
mysql> SELECT LTRIM(' barbar');
-> 'barbar'
```

This function is multibyte safe.

- `MAKE_SET(bits,str1,str2,...)`

Returns a set value (a string containing substrings separated by `,` characters) consisting of the strings that have the corresponding bit in *bits* set. *str1* corresponds to bit 0, *str2* to bit 1, and so on. `NULL` values in *str1*, *str2*, ... are not appended to the result.

```
mysql> SELECT MAKE_SET(1,'a','b','c');
-> 'a'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice','world');
-> 'hello,world'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
-> 'hello'
mysql> SELECT MAKE_SET(0,'a','b','c');
-> ''
```

- `MID(str,pos,len)`

`MID(str,pos,len)` is a synonym for `SUBSTRING(str,pos,len)`.

- `OCT(N)`

Returns a string representation of the octal value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,8)`. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT OCT(12);
-> '14'
```

- `OCTET_LENGTH(str)`

`OCTET_LENGTH()` is a synonym for `LENGTH()`.

- `ORD(str)`

If the leftmost character of the string *str* is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code * 256)
+ (3rd byte code * 256^2) ...
```

If the leftmost character is not a multibyte character, `ORD()` returns the same value as the `ASCII()` function.

```
mysql> SELECT ORD('2');
-> 50
```

- `POSITION(substr IN str)`

`POSITION(substr IN str)` is a synonym for `LOCATE(substr,str)`.

- `QUOTE(str)`

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash (\), single quote ('), ASCII `NUL`, and Control+Z preceded by a backslash. If the argument is `NULL`, the return value is the word "NULL" without enclosing single quotation marks.

```
mysql> SELECT QUOTE('Don\t!');
-> 'Don\t!'
mysql> SELECT QUOTE(NULL);
-> NULL
```

For comparison, see the quoting rules for literal strings and within the C API in [Section 9.1.1, "String Literals"](#), and [Section 23.7.6.53, "mysql_real_escape_string\(\)"](#).

- `REPEAT(str,count)`

Returns a string consisting of the string *str* repeated *count* times. If *count* is less than 1, returns an empty string. Returns `NULL` if *str* or *count* are `NULL`.

```
mysql> SELECT REPEAT('MySQL', 3);
-> 'MySQLMySQLMySQL'
```

- `REPLACE(str,from_str,to_str)`

Returns the string *str* with all occurrences of the string *from_str* replaced by the string *to_str*. `REPLACE()` performs a case-sensitive match when searching for *from_str*.

```
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multibyte safe.

- `REVERSE(str)`

Returns the string *str* with the order of the characters reversed.

```
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multibyte safe.

- `RIGHT(str,len)`

Returns the rightmost *len* characters from the string *str*, or `NULL` if any argument is `NULL`.

```
mysql> SELECT RIGHT('foobarbar', 4);
-> 'rbar'
```

This function is multibyte safe.

- `RPAD(str,len,padstr)`

Returns the string *str*, right-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

```
mysql> SELECT RPAD('hi',5,'?');
-> 'hi???'
mysql> SELECT RPAD('hi',1,'?');
-> 'h'
```

This function is multibyte safe.

- `RTRIM(str)`

Returns the string *str* with trailing space characters removed.

```
mysql> SELECT RTRIM('barbar ');
-> 'barbar'
```

This function is multibyte safe.

- `SOUNDEX(str)`

Returns a soundex string from *str*. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex string. All nonalphabetic characters in *str* are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

Important

When using `SOUNDEX()`, you should be aware of the following limitations:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
- This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including `utf-8`. See Bug #22638 for more information.

```
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
```

Note

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

- `expr1 SOUNDS LIKE expr2`

This is the same as `SOUNDEX(expr1) = SOUNDEX(expr2)`.

- `SPACE(N)`

Returns a string consisting of *N* space characters.

```
mysql> SELECT SPACE(6);
-> '      '
```

- `SUBSTR(str,pos)`, `SUBSTR(str FROM pos)`, `SUBSTR(str,pos,len)`, `SUBSTR(str FROM pos FOR len)`

`SUBSTR()` is a synonym for `SUBSTRING()`.

- `SUBSTRING(str,pos)`, `SUBSTRING(str FROM pos)`, `SUBSTRING(str,pos,len)`, `SUBSTRING(str FROM pos FOR len)`

The forms without a *len* argument return a substring from string *str* starting at position *pos*. The forms with a *len* argument return a substring *len* characters long from string *str*, starting at position *pos*. The forms that use `FROM` are standard SQL syntax. It is also possible to use a negative value for *pos*. In this case, the beginning of the substring is *pos* characters from the end of the

string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function. A value of 0 for *pos* returns an empty string.

For all forms of `SUBSTRING()`, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

```
mysql> SELECT SUBSTRING('Quadratically',5);
      -> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
      -> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
      -> 'ratica'
mysql> SELECT SUBSTRING('Sakila', -3);
      -> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
      -> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
      -> 'ki'
```

This function is multibyte safe.

If *len* is less than 1, the result is the empty string.

- `SUBSTRING_INDEX(str, delim, count)`

Returns the substring from string *str* before *count* occurrences of the delimiter *delim*. If *count* is positive, everything to the left of the final delimiter (counting from the left) is returned. If *count* is negative, everything to the right of the final delimiter (counting from the right) is returned. `SUBSTRING_INDEX()` performs a case-sensitive match when searching for *delim*.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
      -> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
      -> 'mysql.com'
```

This function is multibyte safe.

- `TRIM([{BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)`

Returns the string *str* with all *remstr* prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. *remstr* is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM(' bar ');
      -> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');
      -> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
      -> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxyz');
      -> 'barx'
```

This function is multibyte safe.

- `UCASE(str)`

`UCASE()` is a synonym for `UPPER()`.

- `UNHEX(str)`

For a string argument *str*, `UNHEX(str)` interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.

```
mysql> SELECT UNHEX('4D7953514C');
```

```

-> 'MySQL'
mysql> SELECT X'4D7953514C';
-> 'MySQL'
mysql> SELECT UNHEX(HEX('string'));
-> 'string'
mysql> SELECT HEX(UNHEX('1267'));
-> '1267'

```

The characters in the argument string must be legal hexadecimal digits: '0' .. '9', 'A' .. 'F', 'a' .. 'f'. If the argument contains any nonhexadecimal digits, the result is `NULL`:

```

mysql> SELECT UNHEX('GG');
+-----+
| UNHEX('GG') |
+-----+
| NULL        |
+-----+

```

A `NULL` result can occur if the argument to `UNHEX()` is a `BINARY` column, because values are padded with `0x00` bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a `CHAR(3)` column as '41 ' and retrieved as '41' (with the trailing pad space stripped), so `UNHEX()` for the column value returns 'A'. By contrast '41' is stored into a `BINARY(3)` column as '41\0' and retrieved as '41\0' (with the trailing pad `0x00` byte not stripped). '\0' is not a legal hexadecimal digit, so `UNHEX()` for the column value returns `NULL`.

For a numeric argument *N*, the inverse of `HEX(N)` is not performed by `UNHEX()`. Use `CONV(HEX(N), 16, 10)` instead. See the description of `HEX()`.

- `UPPER(str)`

Returns the string *str* with all characters changed to uppercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```

mysql> SELECT UPPER('Hej');
-> 'HEJ'

```

See the description of `LOWER()` for information that also applies to `UPPER()`, such as information about how to perform lettercase conversion of binary strings (`BINARY`, `VARBINARY`, `BLOB`) for which these functions are ineffective.

This function is multibyte safe.

12.7.1 String Comparison Functions and Operators

Table 12.12 String Comparison Functions and Operators

| Name | Description |
|-----------------------|-------------------------------------|
| <code>LIKE</code> | Simple pattern matching |
| <code>NOT LIKE</code> | Negation of simple pattern matching |
| <code>STRCMP()</code> | Compare two strings |

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case-sensitive, the comparison is performed in case-sensitive fashion.

- `expr LIKE pat [ESCAPE 'escape_char']`

Pattern matching using an SQL pattern. Returns 1 (`TRUE`) or 0 (`FALSE`). If either *expr* or *pat* is `NULL`, the result is `NULL`.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Per the SQL standard, `LIKE` performs matching on a per-character basis, thus it can produce results different from the `=` comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
+-----+
|                                     0 |
+-----+
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' = 'ae' COLLATE latin1_german2_ci |
+-----+
|                                     1 |
+-----+
```

In particular, trailing spaces are significant, which is not true for `CHAR` or `VARCHAR` comparisons performed with the `=` operator:

```
mysql> SELECT 'a' = 'a ', 'a' LIKE 'a ';
+-----+-----+
| 'a' = 'a ' | 'a' LIKE 'a ' |
+-----+-----+
|          1 |              0 |
+-----+-----+
1 row in set (0.00 sec)
```

With `LIKE` you can use the following two wildcard characters in the pattern:

- `%` matches any number of characters, even zero characters.
- `_` matches exactly one character.

```
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, `\` is assumed.

- `\%` matches one `%` character.
- `_` matches one `_` character.

```
mysql> SELECT 'David!' LIKE 'David\_';
-> 0
mysql> SELECT 'David_' LIKE 'David\_';
-> 1
```

To specify a different escape character, use the `ESCAPE` clause:

```
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
-> 1
```

The escape sequence should be empty or one character long. The expression must evaluate as a constant at execution time. If the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case-sensitive unless one of the operands is case-sensitive (uses a case-sensitive collation or is a binary string):

```
mysql> SELECT 'abc' LIKE 'ABC';
```

```

-> 1
mysql> SELECT 'abc' LIKE _latin1 'ABC' COLLATE latin1_general_cs;
-> 0
mysql> SELECT 'abc' LIKE _latin1 'ABC' COLLATE latin1_bin;
-> 0
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0

```

As an extension to standard SQL, MySQL permits `LIKE` on numeric expressions.

```

mysql> SELECT 10 LIKE '1%';
-> 1

```

Note

Because MySQL uses C escape syntax in strings (for example, `\n` to represent a newline character), you must double any `\` that you use in `LIKE` strings. For example, to search for `\n`, specify it as `\\n`. To search for `\`, specify it as `\\\\`; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

Exception: At the end of the pattern string, backslash can be specified as `\\`. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```

mysql> SELECT filename FROM t1;
+-----+
| filename |
+-----+
| C:       |
| C:\     |
| C:\Programs |
| C:\Programs\ |
+-----+

```

To test for values that end with backslash, you can match the values using either of the following patterns:

```

mysql> SELECT filename, filename LIKE '%\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\' |
+-----+-----+
| C:       | 0 |
| C:\     | 1 |
| C:\Programs | 0 |
| C:\Programs\ | 1 |
+-----+-----+

mysql> SELECT filename, filename LIKE '%\\\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\\\' |
+-----+-----+
| C:       | 0 |
| C:\     | 1 |
| C:\Programs | 0 |
| C:\Programs\ | 1 |
+-----+-----+

```

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

Note

Aggregate queries involving `NOT LIKE` comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%';` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%';` would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving `NULL` and comparisons using `NOT RLIKE` or `NOT REGEXP`. In such cases, you must test explicitly for `NOT NULL` using `OR` (and not `AND`), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- `STRCMP(expr1,expr2)`

`STRCMP()` returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
-> -1
mysql> SELECT STRCMP('text2', 'text');
-> 1
mysql> SELECT STRCMP('text', 'text');
-> 0
```

`STRCMP()` performs the comparison using the collation of the arguments.

```
mysql> SET @s1 = _latin1 'x' COLLATE latin1_general_ci;
mysql> SET @s2 = _latin1 'X' COLLATE latin1_general_ci;
mysql> SET @s3 = _latin1 'x' COLLATE latin1_general_cs;
mysql> SET @s4 = _latin1 'X' COLLATE latin1_general_cs;
mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
+-----+-----+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
+-----+-----+
| 0 | 1 |
+-----+-----+
```

If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See [Section 10.8.4, “Collation Coercibility in Expressions”](#).

```
mysql> SELECT STRCMP(@s1, @s3);
ERROR 1267 (HY000): Illegal mix of collations (latin1_general_ci,IMPLICIT)
and (latin1_general_cs,IMPLICIT) for operation 'strcmp'
mysql> SELECT STRCMP(@s1, @s3 COLLATE latin1_general_ci);
+-----+
| STRCMP(@s1, @s3 COLLATE latin1_general_ci) |
+-----+
| 0 |
+-----+
```

12.7.2 Regular Expressions

Table 12.13 Regular Expression Functions and Operators

| Name | Description |
|-------------------------|---|
| <code>NOT REGEXP</code> | Negation of REGEXP |
| <code>REGEXP</code> | Whether string matches regular expression |
| <code>RLIKE</code> | Whether string matches regular expression |

A regular expression is a powerful way of specifying a pattern for a complex search. This section discusses the operators available for regular expression matching and illustrates, with examples, some of the special characters and constructs that can be used for regular expression operations. See also [Section 3.3.4.7, “Pattern Matching”](#).

MySQL uses Henry Spencer's implementation of regular expressions, which is aimed at conformance with POSIX 1003.2. MySQL uses the extended version to support regular expression pattern-matching operations in SQL statements. This section does not contain all the details that can be found in Henry Spencer's `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory.

- [Regular Expression Operators](#)
- [Regular Expression Syntax](#)

Regular Expression Operators

- `expr NOT REGEXP pat, expr NOT RLIKE pat`

This is the same as `NOT (expr REGEXP pat)`.

- `expr REGEXP pat, expr RLIKE pat`

Returns 1 if the string `expr` matches the regular expression specified by the pattern `pat`, 0 otherwise. If either `expr` or `pat` is `NULL`, the return value is `NULL`.

`RLIKE` is a synonym for `REGEXP`, provided for `mSQL` compatibility.

The pattern can be an extended regular expression, the syntax for which is discussed in [Regular Expression Syntax](#). The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Note

Because MySQL uses the C escape syntax in strings (for example, `\n` to represent the newline character), you must double any `\` that you use in your `REGEXP` arguments.

Regular expression operations use the character set and collation of the string expression and pattern arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in [Section 10.8.4, “Collation Coercibility in Expressions”](#). If either argument is a binary string, the arguments are handled in case-sensitive fashion as binary strings.

```
mysql> SELECT 'Michael!' REGEXP '.*';
+-----+
| 'Michael!' REGEXP '.*' |
+-----+
|                        1 |
+-----+
mysql> SELECT 'new*\n*line' REGEXP 'new\\*.*\\*line';
+-----+
| 'new*\n*line' REGEXP 'new\\*.*\\*line' |
+-----+
|                                         0 |
+-----+
```

```

+-----+
mysql> SELECT 'a' REGEXP '^[a-d]';
+-----+
| 'a' REGEXP '^[a-d]' |
+-----+
| 1 |
+-----+
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
+-----+
| 'a' REGEXP 'A' | 'a' REGEXP BINARY 'A' |
+-----+
| 1 | 0 |
+-----+

```

Warning

The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

Regular Expression Syntax

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|world` contains the `|` alternation operator and matches either the `hello` or `world`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

A regular expression for the `REGEXP` operator may use any of the following special characters and constructs:

- `^`

Match the beginning of a string.

```

mysql> SELECT 'fo\nfo' REGEXP '^fo$';      -> 0
mysql> SELECT 'fofo' REGEXP '^fo';        -> 1

```

- `$`

Match the end of a string.

```

mysql> SELECT 'fo\no' REGEXP '^fo\no$';    -> 1
mysql> SELECT 'fo\no' REGEXP '^fo$';       -> 0

```

- `.`

Match any character (including carriage return and newline).

```

mysql> SELECT 'fofo' REGEXP '^f.*$';        -> 1
mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$';   -> 1

```

- `a*`

Match any sequence of zero or more `a` characters.

```

mysql> SELECT 'Ban' REGEXP '^Ba*n';         -> 1
mysql> SELECT 'Baaan' REGEXP '^Ba*n';      -> 1
mysql> SELECT 'Bn' REGEXP '^Ba*n';         -> 1

```

- `a+`

Match any sequence of one or more `a` characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba+n';          -> 1
mysql> SELECT 'Bn' REGEXP '^Ba+n';          -> 0
```

- `a?`

Match either zero or one `a` character.

```
mysql> SELECT 'Bn' REGEXP '^Ba?n';          -> 1
mysql> SELECT 'Ban' REGEXP '^Ba?n';         -> 1
mysql> SELECT 'Baan' REGEXP '^Ba?n';        -> 0
```

- `de|abc`

Alternation; match either of the sequences `de` or `abc`.

```
mysql> SELECT 'pi' REGEXP 'pi|apa';          -> 1
mysql> SELECT 'axe' REGEXP 'pi|apa';         -> 0
mysql> SELECT 'apa' REGEXP 'pi|apa';         -> 1
mysql> SELECT 'apa' REGEXP '^ (pi|apa) $';    -> 1
mysql> SELECT 'pi' REGEXP '^ (pi|apa) $';    -> 1
mysql> SELECT 'pix' REGEXP '^ (pi|apa) $';   -> 0
```

- `(abc)*`

Match zero or more instances of the sequence `abc`.

```
mysql> SELECT 'pi' REGEXP '^ (pi) * $';      -> 1
mysql> SELECT 'pip' REGEXP '^ (pi) * $';     -> 0
mysql> SELECT 'pipi' REGEXP '^ (pi) * $';    -> 1
```

- `{1}, {2, 3}`

Repetition; `{n}` and `{m,n}` notation provide a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. `m` and `n` are integers.

- `a*`

Can be written as `a{0,}`.

- `a+`

Can be written as `a{1,}`.

- `a?`

Can be written as `a{0,1}`.

To be more precise, `a{n}` matches exactly `n` instances of `a`. `a{n,}` matches `n` or more instances of `a`. `a{m,n}` matches `m` through `n` instances of `a`, inclusive. If both `m` and `n` are given, `m` must be less than or equal to `n`.

`m` and `n` must be in the range from 0 to `RE_DUP_MAX` (default 255), inclusive.

```
mysql> SELECT 'abcde' REGEXP 'a[bcd]{2}e';   -> 0
mysql> SELECT 'abcde' REGEXP 'a[bcd]{3}e';   -> 1
mysql> SELECT 'abcde' REGEXP 'a[bcd]{1,10}e'; -> 1
```

- `[a-dX], [^a-dX]`

Matches any character that is (or is not, if `^` is used) either `a`, `b`, `c`, `d` or `X`. A `-` character between two other characters forms a range that matches all characters from the first character to the second.

For example, `[0-9]` matches any decimal digit. To include a literal `]` character, it must immediately

follow the opening bracket [. To include a literal - character, it must be written first or last. Any character that does not have a defined special meaning inside a [] pair matches only itself.

```
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]';          -> 1
mysql> SELECT 'aXbc' REGEXP '^[a-dXYZ]$';        -> 0
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]+';         -> 1
mysql> SELECT 'aXbc' REGEXP '^^[a-dXYZ]+$';      -> 0
mysql> SELECT 'gheis' REGEXP '^^[a-dXYZ]+$';    -> 1
mysql> SELECT 'gheisa' REGEXP '^^[a-dXYZ]+$';   -> 0
```

- [.characters.]

Within a bracket expression (written using [and]), matches the sequence of characters of that collating element. `characters` is either a single character or a character name like `newline`. The following table lists the permissible character names.

The following table shows the permissible character names and the characters that they match. For characters given as numeric values, the values are represented in octal.

| Name | Character | Name | Character |
|-------------------|-----------|------------------|-----------|
| NUL | 0 | SOH | 001 |
| STX | 002 | ETX | 003 |
| EOT | 004 | ENQ | 005 |
| ACK | 006 | BEL | 007 |
| alert | 007 | BS | 010 |
| backspace | '\b' | HT | 011 |
| tab | '\t' | LF | 012 |
| newline | '\n' | VT | 013 |
| vertical-tab | '\v' | FF | 014 |
| form-feed | '\f' | CR | 015 |
| carriage-return | '\r' | SO | 016 |
| SI | 017 | DLE | 020 |
| DC1 | 021 | DC2 | 022 |
| DC3 | 023 | DC4 | 024 |
| NAK | 025 | SYN | 026 |
| ETB | 027 | CAN | 030 |
| EM | 031 | SUB | 032 |
| ESC | 033 | IS4 | 034 |
| FS | 034 | IS3 | 035 |
| GS | 035 | IS2 | 036 |
| RS | 036 | IS1 | 037 |
| US | 037 | space | ' ' |
| exclamation-mark | '!' | quotation-mark | '\"' |
| number-sign | '#' | dollar-sign | '\$' |
| percent-sign | '%' | ampersand | '&' |
| apostrophe | '\'' | left-parenthesis | '(' |
| right-parenthesis | ')' | asterisk | '*' |
| plus-sign | '+' | comma | ',' |
| hyphen | '-' | hyphen-minus | '-' |

| Name | Character | Name | Character |
|----------------------|-----------|---------------------|-----------|
| period | '.' | full-stop | '.' |
| slash | '/' | solidus | '/' |
| zero | '0' | one | '1' |
| two | '2' | three | '3' |
| four | '4' | five | '5' |
| six | '6' | seven | '7' |
| eight | '8' | nine | '9' |
| colon | ':' | semicolon | ';' |
| less-than-sign | '<' | equals-sign | '=' |
| greater-than-sign | '>' | question-mark | '?' |
| commercial-at | '@' | left-square-bracket | '[' |
| backslash | '\' | reverse-solidus | '\' |
| right-square-bracket | ']' | circumflex | '^' |
| circumflex-accent | '^' | underscore | '_' |
| low-line | '_' | grave-accent | '`' |
| left-brace | '{' | left-curly-bracket | '{' |
| vertical-line | ' ' | right-brace | '}' |
| right-curly-bracket | '}' | tilde | '~' |
| DEL | 177 | | |

```
mysql> SELECT '~' REGEXP '[[.~.]]';          -> 1
mysql> SELECT '~' REGEXP '[[.tilde.]]';     -> 1
```

- [=character_class=]

Within a bracket expression (written using [and]), [=character_class=] represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if o and (+) are the members of an equivalence class, [[=o=]], [[=(+)=]], and [o(+)] are all synonymous. An equivalence class may not be used as an endpoint of a range.

- [:character_class:]

Within a bracket expression (written using [and]), [:character_class:] represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the [ctype\(3\)](#) manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

| Character Class Name | Meaning |
|----------------------|-------------------------|
| alnum | Alphanumeric characters |
| alpha | Alphabetic characters |
| blank | Whitespace characters |
| cntrl | Control characters |

| Character Class Name | Meaning |
|----------------------|--|
| <code>digit</code> | Digit characters |
| <code>graph</code> | Graphic characters |
| <code>lower</code> | Lowercase alphabetic characters |
| <code>print</code> | Graphic or space characters |
| <code>punct</code> | Punctuation characters |
| <code>space</code> | Space, tab, newline, and carriage return |
| <code>upper</code> | Uppercase alphabetic characters |
| <code>xdigit</code> | Hexadecimal digit characters |

```
mysql> SELECT 'justalnums' REGEXP '[:alnum:]+';      -> 1
mysql> SELECT '!!!' REGEXP '[:alnum:]+';           -> 0
```

- `[[:<:]]`, `[[:>:]]`

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the `alnum` class or an underscore (`_`).

```
mysql> SELECT 'a word a' REGEXP '[[:<:]]word[[:>:]]'; -> 1
mysql> SELECT 'a xword a' REGEXP '[[:<:]]word[[:>:]]'; -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (`\`) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT '1+2' REGEXP '1+2';                  -> 0
mysql> SELECT '1+2' REGEXP '1\\+2';                -> 0
mysql> SELECT '1+2' REGEXP '1\\\\+2';               -> 1
```

12.7.3 Character Set and Collation of Function Results

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string with the same character string and collation as `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

Note

The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has the `binary` character set and collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` for a binary string argument:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+-----+-----+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+-----+-----+
| binary              | binary                 |
+-----+-----+
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE Y` occurs, use `Y`.
- If explicit `COLLATE Y` and `COLLATE Z` occur, raise an error.
- Otherwise, if all collations are `Y`, use `Y`.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see Section 10.4, “Connection Character Sets and Collations”). This applies only to `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

If there is any question about the character set or collation of the result returned by a string function, use the `CHARSET()` or `COLLATION()` function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+-----+-----+-----+
| USER()          | CHARSET(USER()) | COLLATION(USER()) |
+-----+-----+-----+
| test@localhost | utf8            | utf8_general_ci  |
+-----+-----+-----+
mysql> SELECT CHARSET(COMPRESS('abc')), COLLATION(COMPRESS('abc'));
+-----+-----+
| CHARSET(COMPRESS('abc')) | COLLATION(COMPRESS('abc')) |
+-----+-----+
| binary                   | binary                     |
+-----+-----+
```

12.8 What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar*.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

| Monday | Tuesday | Wednesday | Thursday | Friday | Saturday | Sunday |
|--------|---------|-----------|----------|--------|----------|--------|
| 1 | 2 | 3 | 4 | 15 | 16 | 17 |
| 18 | 19 | 20 | 21 | 22 | 23 | 24 |
| 25 | 26 | 27 | 28 | 29 | 30 | 31 |

There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL `DATE` or `DATETIME` values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

12.9 Full-Text Search Functions

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
```

```
search_modifier:
{
  | IN NATURAL LANGUAGE MODE
  | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
  | IN BOOLEAN MODE
  | WITH QUERY EXPANSION
}
```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `MyISAM` tables. (In MySQL 5.6 and up, they can also be used with `InnoDB` tables.) Full-text indexes can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.
- A `FULLTEXT` index definition can be given in the `CREATE TABLE` statement when a table is created, or added later using `ALTER TABLE` or `CREATE INDEX`.
- For large data sets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH() ... AGAINST` syntax. `MATCH()` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators, with the exception of double quote (") characters. The stopword list applies. In addition, words that are present in 50% or more of the rows are considered common and do not match.

Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given. For more information, see [Section 12.9.1, “Natural Language Full-Text Searches”](#).

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Common words such as “some” or “then” are stopwords and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see [Section 12.9.2, “Boolean Full-Text Searches”](#).
- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` or `WITH QUERY EXPANSION` modifier specifies a query expansion search. For more information, see [Section 12.9.3, “Full-Text Searches with Query Expansion”](#).

Constraints on full-text searching are listed in [Section 12.9.5, “Full-Text Restrictions”](#).

The `myisam_ftdump` utility can be used to dump the contents of a full-text index. This may be helpful for debugging full-text queries. See [Section 4.6.2, “myisam_ftdump — Display Full-Text Index information”](#).

12.9.1 Natural Language Full-Text Searches

By default or with the `IN NATURAL LANGUAGE MODE` modifier, the `MATCH()` function performs a natural language search for a string against a *text collection*. A collection is a set of one or more columns included in a `FULLTEXT` index. The search string is given as the argument to `AGAINST()`. For each row in the table, `MATCH()` returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the `MATCH()` list.

```
mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)

```

By default, the search is performed in case-insensitive fashion. However, you can perform a case-sensitive full-text search by using a binary collation for the indexed columns. For example, a column that uses the `latin1` character set of can be assigned a collation of `latin1_bin` to make it case-sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row (document), the number of unique words in the row, the total number of words in the collection, and the number of rows that contain a particular word.

Note

The term “document” may be used interchangeably with the term “row”, and both terms refer to the indexed part of the row. The term “collection” refers to the indexed columns and encompasses all rows.

To simply count matches, you could use a query like this:

```
mysql> SELECT COUNT(*) FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+
| COUNT(*) |
+-----+
| 2 |
+-----+
1 row in set (0.00 sec)
```

However, you might find it quicker to rewrite the query as follows:

```
mysql> SELECT
-> COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
-> AS count
-> FROM articles;
+-----+
| count |
+-----+
|      2 |
+-----+
1 row in set (0.03 sec)
```

The first query sorts the results by relevance whereas the second does not. However, the second query performs a full table scan and the first does not. The first may be faster if the search matches few rows; otherwise, the second may be faster because it would read many rows anyway.

For natural-language full-text searches, it is a requirement that the columns named in the `MATCH()` function be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. If you wanted to search the `title` or `body` separately, you would need to create separate `FULLTEXT` indexes for each column.

It is also possible to perform a boolean search or a search with query expansion. These search types are described in [Section 12.9.2, "Boolean Full-Text Searches"](#), and [Section 12.9.3, "Full-Text Searches with Query Expansion"](#).

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. A boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title,body)
-> AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
-> FROM articles;
+-----+-----+
| id | score |
+-----+-----+
| 1 | 0.65545833110809 |
| 2 | 0 |
| 3 | 0.66266459226608 |
| 4 | 0 |
| 5 | 0 |
| 6 | 0 |
+-----+-----+
6 rows in set (0.00 sec)
```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```
mysql> SELECT id, body, MATCH (title,body) AGAINST
-> ('Security implications of running MySQL as root'
-> IN NATURAL LANGUAGE MODE) AS score
-> FROM articles WHERE MATCH (title,body) AGAINST
-> ('Security implications of running MySQL as root'
-> IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | body | score |
+-----+-----+-----+
| 4 | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
| 6 | When configured properly, MySQL ... | 1.3114095926285 |
+-----+-----+-----+
```

```
2 rows in set (0.00 sec)
```

A phrase that is enclosed within double quote (") characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase". If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes ('), but not more than one in a row. This means that `aaa'bbb` is regarded as one word, but `aaa 'bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; `'aaa'bbb'` would be parsed as `aaa'bbb`.

The `FULLTEXT` parser determines where words start and end by looking for certain delimiter characters; for example, (space), , (comma), and . (period). If words are not separated by delimiters (as in, for example, Chinese), the `FULLTEXT` parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index, you must preprocess them so that they are separated by some arbitrary delimiter.

It is possible to write a plugin that replaces the built-in full-text parser. For details, see [Section 24.2, "The MySQL Plugin API"](#). For example parser plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is four characters.
- Words in the stopword list are ignored. A stopword is a word such as "the" or "some" that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overwritten by a user-defined list.

The default stopword list is given in [Section 12.9.4, "Full-Text Stopwords"](#). The default minimum word length and stopword list can be changed as described in [Section 12.9.6, "Fine-Tuning MySQL Full-Text Search"](#).

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Consequently, a word that is present in many documents has a lower weight (and may even have a zero weight), because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row.

Such a technique works best with large collections (in fact, it was carefully tuned this way). For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results. For example, although the word "MySQL" is present in every row of the `articles` table shown earlier, a search for the word produces no results:

```
mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word "MySQL" is present in at least 50% of the rows. As such, it is effectively treated as a stopword. For large data sets, this is the most desirable behavior: A natural language query should not return every second row from a 1GB table. For small data sets, it may be less desirable.

A word that matches half of the rows in a table is less likely to locate relevant documents. In fact, it most likely finds plenty of irrelevant documents. We all know this happens far too often when we are trying to find something on the Internet with a search engine. It is with this reasoning that rows

containing the word are assigned a low semantic value for *the particular data set in which they occur*. A given word may reach the 50% threshold in one data set but not another.

The 50% threshold has a significant implication when you first try full-text searching to see how it works: If you create a table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results. Be sure to insert at least three rows, and preferably many more. Users who need to bypass the 50% limitation can use the boolean search mode; see [Section 12.9.2, “Boolean Full-Text Searches”](#).

12.9.2 Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the `IN BOOLEAN MODE` modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the `+` and `-` operators indicate that a word is required to be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do *not* contain the word “YourSQL”:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
-> AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

| id | title | body |
|----|-----------------------|-------------------------------------|
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
| 2 | How To Use MySQL Well | After you went through a ... |
| 3 | Optimizing MySQL | In this tutorial we will show ... |
| 4 | 1001 MySQL Tricks | 1. Never run mysqld as root. 2. ... |
| 6 | MySQL Security | When configured properly, MySQL ... |

Note

In implementing this feature, MySQL uses what is sometimes referred to as *implied Boolean logic*, in which

- `+` stands for `AND`
- `-` stands for `NOT`
- `[no operator]` implies `OR`

Boolean full-text searches have these characteristics:

- They do not use the 50% threshold.
- They do not automatically sort rows in order of decreasing relevance. You can see this from the preceding query result: The row with the highest relevance is the one that contains “MySQL” twice, but it is listed last, not first.
- They can work even without a `FULLTEXT` index, although a search executed in this fashion would be quite slow.
- The minimum and maximum word length full-text parameters apply.
- The stopword list applies.

The boolean full-text search capability supports the following operators:

- `+`

A leading plus sign indicates that this word *must* be present in each row that is returned.

- `-`

A leading minus sign indicates that this word must *not* be present in any of the rows that are returned.

Note: The `-` operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by `-` returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither `+` nor `-` is specified) the word is optional, but the rows that contain it are rated higher. This mimics the behavior of `MATCH() . . . AGAINST()` without the `IN BOOLEAN MODE` modifier.

- `>` `<`

These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The `>` operator increases the contribution and the `<` operator decreases it. See the example following this list.

- `()`

Parentheses group words into subexpressions. Parenthesized groups can be nested.

- `~`

A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the `-` operator.

- `*`

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it should be *appended* to the word to be affected. Words match if they begin with the word preceding the `*` operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short (as determined from the `ft_min_word_len` setting) or a stopword. This occurs because the word is not seen as too short or a stopword, but as a prefix that must be present in the document in the form of a word that begins with the prefix. Suppose that `ft_min_word_len=4`. Then a search for `'+word +the*'` will likely return fewer rows than a search for `'+word +the'`:

- The former query remains as is and requires both `word` and `the*` (a word starting with `the`) to be present in the document.
- The latter query is transformed to `+word` (requiring only `word` to be present). `the` is both too short and a stopword, and either condition is enough to cause it to be ignored.

- `"`

A phrase that is enclosed within double quote (`"`) characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"`.

If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`

Find rows that contain at least one of the two words.

- `'+apple +juice'`

Find rows that contain both words.

- `'+apple macintosh'`

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- `'+apple -macintosh'`

Find rows that contain the word “apple” but not “macintosh”.

- `'+apple ~macintosh'`

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for `'+apple -macintosh'`, for which the presence of “macintosh” causes the row not to be returned at all.

- `'+apple +(>turnover <strudel)'`

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- `'apple*'`

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- `'"some words"'`

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the `"` characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

12.9.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' WITH QUERY EXPANSION);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
```

```

+-----+
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
| 3 | Optimizing MySQL | In this tutorial we will show ... |
+-----+
3 rows in set (0.00 sec)

```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

Note

Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, it is meaningful to use only when a search phrase is rather short.

12.9.4 Full-Text Stopwords

The stopword list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses may occur for stopword lookups if the stopword file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopword lookups depends on the server collation. For example, lookups are case-insensitive if the collation is `latin1_swedish_ci`, whereas lookups are case-sensitive if the collation is `latin1_general_cs` or `latin1_bin`.

The stopword file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, or `utf32`.

The following list shows the default full-text stopwords. In a MySQL source distribution, you can find this list in the `storage/myisam/ft_static.c` file.

| | | | | |

12.9.5 Full-Text Restrictions

- Full-text searches are supported for [MyISAM](#) tables only. (In MySQL 5.6 and up, they can also be used with [InnoDB](#) tables.)
- Full-text searches are not supported for partitioned tables. See [Section 19.5, “Restrictions and Limitations on Partitioning”](#).
- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the `utf8` character set can be used, but not the `ucs2` character set. However, although `FULLTEXT` indexes on `ucs2` columns cannot be used, you can perform `IN BOOLEAN MODE` searches on a `ucs2` column that has no such index.

The remarks for `utf8` also apply to `utf8mb4`, and the remarks for `ucs2` also apply to `utf16` and `utf32`.

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the `FULLTEXT` parser *cannot determine where words begin and end in these and other such languages*. The implications of this and some workarounds for the problem are described in [Section 12.9, “Full-Text Search Functions”](#).
- Although the use of multiple character sets within a single table is supported, all columns in a `FULLTEXT` index must use the same character set and collation.
- The `MATCH()` column list must match exactly the column list in some `FULLTEXT` index definition for the table, unless this `MATCH()` is `IN BOOLEAN MODE`. Boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.
- The argument to `AGAINST()` must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.
- Index hints are more limited for `FULLTEXT` searches than for non-`FULLTEXT` searches. See [Section 8.9.3, “Index Hints”](#).
- The `%` character is not a supported wildcard character for full-text searches.

12.9.6 Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See [Section 2.9, “Installing MySQL from Source”](#).

Full-text search is carefully tuned for the most effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the `FULLTEXT` indexes in your tables. Instructions for doing so are given later in this section.

- The minimum and maximum lengths of words to be indexed are defined by the `ft_min_word_len` and `ft_max_word_len` system variables. (See [Section 5.1.7, “Server System Variables”](#).) The default minimum value is four characters; the default maximum is version dependent. If you change

either value, you must rebuild your `FULLTEXT` indexes. For example, if you want three-character words to be searchable, you can set the `ft_min_word_len` variable by putting the following lines in an option file:

```
[mysqld]
ft_min_word_len=3
```

Then restart the server and rebuild your `FULLTEXT` indexes. Note particularly the remarks regarding `myisamchk` in the instructions following this list.

- To override the default stopword list, set the `ft_stopword_file` system variable. (See [Section 5.1.7, “Server System Variables”](#).) The variable value should be the path name of the file containing the stopword list, or the empty string to disable stopword filtering. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. After changing the value of this variable or the contents of the stopword file, restart the server and rebuild your `FULLTEXT` indexes.

The stopword list is free-form. That is, you may use any nonalphanumeric character such as newline, space, or comma to separate stopwords. Exceptions are the underscore character (`_`) and a single apostrophe (`'`) which are treated as part of a word. The character set of the stopword list is the server's default character set; see [Section 10.3.2, “Server Character Set and Collation”](#).

- The 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

Note

By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

- To change the operators used for boolean full-text searches, set the `ft_boolean_syntax` system variable. This variable can be changed while the server is running, but you must have privileges sufficient to set global system variables (see [Section 5.1.8.1, “System Variable Privileges”](#)). No rebuilding of indexes is necessary in this case. See [Section 5.1.7, “Server System Variables”](#), which describes the rules governing how to set this variable.
- If you want to change the set of characters that are considered word characters, you can do so in several ways, as described in the following list. After making the modification, you must rebuild the indexes for each table that contains any `FULLTEXT` indexes. Suppose that you want to treat the hyphen character (`'-`) as a word character. Use one of these methods:
 - Modify the MySQL source: In `storage/myisam/ftdefs.h`, see the `true_word_char()` and `misc_word_char()` macros. Add `'-'` to one of those macros and recompile MySQL.
 - Modify a character set file: This requires no recompilation. The `true_word_char()` macro uses a “character type” table to distinguish letters and numbers from other characters. You can edit the contents of the `<ctype><map>` array in one of the character set XML files to specify that `'-'` is a “letter.” Then use the given character set for your `FULLTEXT` indexes. For information about the `<ctype><map>` array format, see [Section 10.13.1, “Character Definition Arrays”](#).
 - Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation. For general information about adding collations, see [Section 10.14, “Adding](#)

a [Collation to a Character Set](#)". For an example specific to full-text indexing, see [Section 12.9.7, "Adding a Collation for Full-Text Indexing"](#).

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopword file itself, you must rebuild your `FULLTEXT` indexes after making the changes and restarting the server. To rebuild the indexes in this case, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` with the `DROP INDEX` and `ADD INDEX` options to drop and re-create each `FULLTEXT` index. In some cases, this may be faster than a repair operation.

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table will cause the server to see the table as corrupt and in need of repair.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the *default* full-text parameter values for minimum word length, maximum word length, and stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or stopword file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values for `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` for index modification is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

12.9.7 Adding a Collation for Full-Text Indexing

This section describes how to add a new collation for full-text searches. The sample collation is like `latin1_swedish_ci` but treats the '-' character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in [Section 10.14, "Adding a Collation to a Character Set"](#); it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use the following procedure. The instructions here add a collation for a simple character set, which as discussed in [Section 10.14, "Adding a Collation to a Character Set"](#), can be created using a configuration file that describes the character set properties. For a complex character set such as Unicode, create collations using C source files that describe the character set properties.

1. Add a collation to the `Index.xml` file. The collation ID must be unused, so choose a value different from 62 if that ID is already taken on your system.

```
<charset name="latin1">
```

```
...
<collation name="latin1_fulltext_ci" id="62"/>
</charset>
```

2. Declare the sort order for the collation in the `latin1.xml` file. In this case, the order can be copied from `latin1_swedish_ci`:

```
<collation name="latin1_fulltext_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D D7 D8 55 55 55 59 59 DE DF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D F7 D8 55 55 55 59 59 DE FF
</map>
</collation>
```

3. Modify the `ctype` array in `latin1.xml`. Change the value corresponding to 0x2D (which is the code for the '-' character) from 10 (punctuation) to 01 (uppercase letter). In the following array, this is the element in the fourth row down, third value from the end.

```
<ctype>
<map>
00
20 20 20 20 20 20 20 20 20 28 28 28 28 28 20 20
20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
48 10 10 10 10 10 10 10 10 10 10 10 10 01 10 10
84 84 84 84 84 84 84 84 84 84 10 10 10 10 10 10
10 81 81 81 81 81 81 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 01 01 01 01 10 10 10 10 10
10 82 82 82 82 82 82 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 02 02 02 02 10 10 10 10 20
10 00 10 02 10 10 10 10 10 10 01 10 01 00 01 00
00 10 10 10 10 10 10 10 10 10 02 10 02 00 02 01
48 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
01 01 01 01 01 01 01 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 10 01 01 01 01 01 01 01 02
02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 10 02 02 02 02 02 02 02 02
</map>
</ctype>
```

4. Restart the server.
5. To employ the new collation, include it in the definition of columns that are to use it:

```
mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)

mysql> CREATE TABLE t1 (
-> a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
-> FULLTEXT INDEX(a)
-> ) ENGINE=MyISAM;
Query OK, 0 rows affected (0.47 sec)
```

6. Test the collation to verify that hyphen is considered as a word character:

```
mysql> INSERT INTO t1 VALUES ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
```

```
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+-----+
| a      |
+-----+
| ----  |
+-----+
1 row in set (0.00 sec)
```

12.10 Cast Functions and Operators

Table 12.14 Cast Functions and Operators

| Name | Description |
|------------------------|----------------------------------|
| <code>BINARY</code> | Cast a string to a binary string |
| <code>CAST()</code> | Cast a value as a certain type |
| <code>CONVERT()</code> | Cast a value as a certain type |

Cast functions and operators enable conversion of values from one data type to another.

`CONVERT()` with a `USING` clause converts data between different character sets:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT('test' USING utf8);
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8_table (utf8_column)
  SELECT CONVERT(latin1_column USING utf8) FROM latin1_table;
```

To convert strings between different character sets, you can also use `CONVERT()` without `USING`, or `CAST()`:

```
CONVERT(string, CHAR[(N)] CHARACTER SET charset_name)
CAST(string AS CHAR[(N)] CHARACTER SET charset_name)
```

Examples:

```
SELECT CONVERT('test', CHAR CHARACTER SET utf8);
SELECT CAST('test' AS CHAR CHARACTER SET utf8);
```

If you specify `CHARACTER SET charset_name` as just shown, the character set and collation of the result are `charset_name` and the default collation of `charset_name`. If you omit `CHARACTER SET charset_name`, the character set and collation of the result are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see [Section 10.4, “Connection Character Sets and Collations”](#)).

A `COLLATE` clause is not permitted within a `CONVERT()` or `CAST()` call, but you can apply it to the function result. For example, these are legal:

```
SELECT CONVERT('test' USING utf8) COLLATE utf8_bin;
SELECT CONVERT('test', CHAR CHARACTER SET utf8) COLLATE utf8_bin;
SELECT CAST('test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

But these are illegal:

```
SELECT CONVERT('test' USING utf8 COLLATE utf8_bin);
```

```
SELECT CONVERT('test', CHAR CHARACTER SET utf8 COLLATE utf8_bin);
SELECT CAST('test' AS CHAR CHARACTER SET utf8 COLLATE utf8_bin);
```

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings use the `binary` character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, first use the `CONVERT()` or `CAST()` function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion result character set has a case-insensitive collation, a `LIKE` operation is not case-sensitive. That is true for the following operation because the default `latin1` collation (`latin1_swedish_ci`) is not case-sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1)
FROM tbl_name;
```

To specify a particular collation for the converted string, use a `COLLATE` clause following the `CONVERT()` call:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) COLLATE latin1_german1_ci
FROM tbl_name;
```

To use a different character set, substitute its name for `latin1` in the preceding statements (and similarly to use a different collation).

`CONVERT()` and `CAST()` can be used more generally for comparing strings represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:

```
mysql> SET @s1 = _latin1 'abc', @s2 = _latin2 'abc';
mysql> SELECT @s1 = @s2;
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (latin2_general_ci,IMPLICIT) for operation '='
```

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

```
mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
+-----+
| @s1 = CONVERT(@s2 USING latin1) |
+-----+
| 1 |
+-----+
```

For string literals, another way to specify the character set is to use a character set introducer. `_latin1` and `_latin2` in the preceding example are instances of introducers. Unlike conversion functions such as `CAST()`, or `CONVERT()`, which convert a string from one character set to another, an introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see [Section 10.3.8, “Character Set Introducers”](#).

Character set conversion is also useful preceding lettercase conversion of binary strings. `LOWER()` and `UPPER()` are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-----+-----+
| New York   | new york                           |
+-----+-----+
```

Be aware that if you convert an indexed column using `BINARY`, `CAST()`, or `CONVERT()`, MySQL may not be able to use the index efficiently.

The cast functions are useful for creating a column with a specific type in a `CREATE TABLE ... SELECT` statement:

```
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
mysql> SHOW CREATE TABLE new_table\G
***** 1. row *****
      Table: new_table
Create Table: CREATE TABLE `new_table` (
  `c1` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

The cast functions are useful for sorting `ENUM` columns in lexical order. Normally, sorting of `ENUM` columns occurs using the internal numeric values. Casting the values to `CHAR` results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST()` also changes the result if you use it as part of a more complex expression such as `CONCAT('Date: ',CAST(NOW() AS DATE))`.

For temporal values, there is little need to use `CAST()` to extract data in different formats. Instead, use a function such as `EXTRACT()`, `DATE_FORMAT()`, or `TIME_FORMAT()`. See [Section 12.6, “Date and Time Functions”](#).

To cast a string to a number, you normally need do nothing other than use the string value in numeric context:

```
mysql> SELECT 1+'1';
-> 2
```

That is also true for hexadecimal and bit literals, which are binary strings by default:

```
mysql> SELECT X'41', X'41'+0;
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see [Section 12.2, “Type Conversion in Expression Evaluation”](#).

When using an explicit `CAST()` on a `TIMESTAMP` value in a statement that does not select from any tables, the value is treated by MySQL as a string prior to performing any conversion. This results in the value being truncated when casting to a numeric type, as shown here:

```
mysql> SELECT CAST(TIMESTAMP '2014-09-08 18:07:54' AS SIGNED);
+-----+
| CAST(TIMESTAMP '2014-09-08 18:07:54' AS SIGNED) |
+-----+
|                                     2014 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect INTEGER value: '2014-09-08 18:07:54' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

This does not apply when selecting rows from a table, as shown here:

```
mysql> USE test;

Database changed
mysql> CREATE TABLE c_test (col TIMESTAMP);
Query OK, 0 rows affected (0.07 sec)

mysql> INSERT INTO c_test VALUES ('2014-09-08 18:07:54');
Query OK, 1 row affected (0.05 sec)

mysql> SELECT col, CAST(col AS UNSIGNED) AS c_col FROM c_test;
+-----+-----+
| col                | c_col                |
+-----+-----+
| 2014-09-08 18:07:54 | 20140908180754      |
+-----+-----+
1 row in set (0.00 sec)
```

This is a known issue which is resolved in MySQL 5.6.

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as + or -) where one of the operands is an unsigned integer, the result is unsigned by default (see [Section 12.5.1, “Arithmetic Operators”](#)). To override this, use the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT 1 - 2;
-> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
-> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
-> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

The SQL mode affects the result of conversion operations (see [Section 5.1.10, “Server SQL Modes”](#)). Examples:

- For conversion of a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.
- For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

The following list describes the available cast functions and operators:

- `BINARY expr`

The `BINARY` operator converts the expression to a binary string (a string that has the `binary` character set and `binary` collation). A common use for `BINARY` is to force a character string comparison to be done byte by byte using numeric byte values rather than character by character. The `BINARY` operator also causes trailing spaces in comparisons to be significant. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 10.8.5, “The binary Collation Compared to _bin Collations”](#).

```
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
```

```
-> 0
```

In a comparison, `BINARY` affects the entire operation; it can be given before either operand with the same result.

To convert a string expression to a binary string, these constructs are equivalent:

```
BINARY expr
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)
```

If a value is a string literal, it can be designated as a binary string without performing any conversion by using the `_binary` character set introducer:

```
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT _binary 'a' = 'A';
-> 0
```

For information about introducers, see [Section 10.3.8, “Character Set Introducers”](#).

The `BINARY` operator in expressions differs in effect from the `BINARY` attribute in character column definitions. A character column defined with the `BINARY` attribute is assigned the table default character set and the binary (`_bin`) collation of that character set. Every nonbinary character set has a `_bin` collation. For example, if the table default character set is `utf8`, these two column definitions are equivalent:

```
CHAR(10) BINARY
CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin
```

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as the corresponding binary string data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB
```

- `CAST(expr AS type)`

The `CAST()` function takes an expression of any type and produces a result value of the specified type, similar to `CONVERT()`. For more information, see the description of `CONVERT()`.

`CAST()` is standard SQL syntax.

- `CONVERT(expr, type)`, `CONVERT(expr USING transcoding_name)`

The `CONVERT()` function takes an expression of any type and produces a result value of the specified type.

Discussion of `CONVERT(expr, type)` syntax here also applies to `CAST(expr AS type)`, which is equivalent.

`CONVERT(... USING ...)` is standard SQL syntax. The non-`USING` form of `CONVERT()` is ODBC syntax.

`CONVERT()` with `USING` converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string `'abc'` in the default character set to the corresponding string in the `utf8` character set:

```
SELECT CONVERT('abc' USING utf8);
```

`CONVERT()` without `USING` and `CAST()` take an expression and a *type* value specifying the result type. These *type* values are permitted:

- `BINARY[(N)]`

Produces a string with the `BINARY` data type. For a description of how this affects comparisons, see [Section 11.3.3, “The BINARY and VARBINARY Types”](#). If the optional length *N* is given, `BINARY(N)` causes the cast to use no more than *N* bytes of the argument. Values shorter than *N* bytes are padded with `0x00` bytes to a length of *N*.

- `CHAR[(N)] [charset_info]`

Produces a string with the `CHAR` data type. If the optional length *N* is given, `CHAR(N)` causes the cast to use no more than *N* characters of the argument. No padding occurs for values shorter than *N* characters.

With no *charset_info* clause, `CHAR` produces a string with the default character set. To specify the character set explicitly, these *charset_info* values are permitted:

- `CHARACTER SET charset_name`: Produces a string with the given character set.
- `ASCII`: Shorthand for `CHARACTER SET latin1`.
- `UNICODE`: Shorthand for `CHARACTER SET ucs2`.

In all cases, the string has the character set default collation.

- `DATE`

Produces a `DATE` value.

- `DATETIME`

Produces a `DATETIME` value.

- `DECIMAL[(M[, D])]`

Produces a `DECIMAL` value. If the optional *M* and *D* values are given, they specify the maximum number of digits (the precision) and the number of digits following the decimal point (the scale).

- `NCHAR[(N)]`

Like `CHAR`, but produces a string with the national character set. See [Section 10.3.7, “The National Character Set”](#).

Unlike `CHAR`, `NCHAR` does not permit trailing character set information to be specified.

- `SIGNED [INTEGER]`

Produces a signed integer value.

- `TIME`

Produces a `TIME` value.

- `UNSIGNED [INTEGER]`

Produces an unsigned integer value.

12.11 XML Functions

Table 12.15 XML Functions

| Name | Description |
|-----------------------------|---|
| <code>ExtractValue()</code> | Extract a value from an XML string using XPath notation |
| <code>UpdateXML()</code> | Return replaced XML fragment |

This section discusses XML and related functionality in MySQL.

Note

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See [Section 4.5.1, “mysql — The MySQL Command-Line Client”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this manual, and you should refer to the [XML Path Language \(XPath\) 1.0 standard](#) for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Note

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 5.5 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the [MySQL XML User Forum](#).

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax ``${variable_name}` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings will be given if (for example) ``${myvariable}` is used where ``${myvariable}` was intended.

Example:

```
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i = 1, @j = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[${i}]');
+-----+-----+
| @i | ExtractValue(@xml, '//b[${i}]' |
+-----+-----+
| 1 | X |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @j, ExtractValue(@xml, '//b[${j}]');
+-----+-----+
| @j | ExtractValue(@xml, '//b[${j}]' |
+-----+-----+
| 2 | Y |
+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> SELECT @k, ExtractValue(@xml, '//b[$@k]');
+-----+-----+
| @k    | ExtractValue(@xml, '//b[$@k]') |
+-----+-----+
| NULL  |                                |
+-----+-----+
1 row in set (0.00 sec)
```

- **Variables in stored programs (strong checking).** Variables using the syntax `$variable_name` can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```
mysql> DELIMITER |

mysql> CREATE PROCEDURE myproc ()
-> BEGIN
->   DECLARE i INT DEFAULT 1;
->   DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';
->
->   WHILE i < 4 DO
->     SELECT xml, i, ExtractValue(xml, '//a[$i]');
->     SET i = i+1;
->   END WHILE;
-> END |
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;

mysql> CALL myproc();
+-----+-----+-----+
| xml          | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a> | 1 | X                             |
+-----+-----+-----+
1 row in set (0.00 sec)

+-----+-----+-----+
| xml          | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a> | 2 | Y                             |
+-----+-----+-----+
1 row in set (0.01 sec)

+-----+-----+-----+
| xml          | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a> | 3 | Z                             |
+-----+-----+-----+
1 row in set (0.01 sec)
```

Parameters. Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

Note

A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

- `ExtractValue(xml_frag, xpath_expr)`

`ExtractValue()` takes two string arguments, a fragment of XML markup *xml_frag* and an XPath expression *xpath_expr* (also known as a *locator*); it returns the text (CDATA) of the first text node which is a child of the element or elements matched by the XPath expression. In MySQL 5.5, the XPath expression can contain at most 127 characters. (This limitation is lifted in MySQL 5.6.)

Using this function is the equivalent of performing a match using the *xpath_expr* after appending `/text()`. In other words, `ExtractValue('<a>Sakila', '/a/b')` and `ExtractValue('<a>Sakila', '/a/b/text()')` produce the same result.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit `/text()`)—for whatever reason, as long as *xpath_expr* is valid, and *xml_frag* consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in *xml_frag* or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```
mysql> SELECT ExtractValue('<a><b></b></a>', '/a/b');
+-----+
| ExtractValue('<a><b></b></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></c></a>', '/a/b');
+-----+
| ExtractValue('<a><c></c></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a><b></b></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><b></b></a>', 'count(/a/b)') |
+-----+
| 1                                           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></c></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><c></c></a>', 'count(/a/b)') |
+-----+
| 0                                           |
+-----+
1 row in set (0.01 sec)
```

Important

`ExtractValue()` returns only CDATA, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```
mysql> SELECT
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
```

```

-> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/b') AS val4,
-> ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;

+-----+-----+-----+-----+-----+
| val1 | val2 | val3 | val4 | val5 |
+-----+-----+-----+-----+-----+
| ccc  | ddd  | ddd  |      | ddd eee |
+-----+-----+-----+-----+-----+

```

This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()`), in taking into account the collation coercibility of their arguments; see [Section 10.8.4, “Collation Coercibility in Expressions”](#), for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

`NULL` is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```

mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----+-----+
| ExtractValue('<a>c</a><b', '//a') |
+-----+-----+
| NULL |
+-----+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+-----+
| c |
+-----+-----+
1 row in set (0.00 sec)

```

- `UpdateXML(xml_target, xpath_expr, new_xml)`

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user. In MySQL 5.5, the XPath expression can contain at most 127 characters. (This limitation is lifted in MySQL 5.6.)

If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings.

```

mysql> SELECT
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
-> UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
-> \G

***** 1. row *****
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>

```

**Note**

A discussion in depth of XPath syntax and usage are beyond the scope of this manual. Please see the [XML Path Language \(XPath\) 1.0 specification](#) for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- `/tag`

Matches `<tag/>` if and only if `<tag/>` is the root element.

Example: `/a` has a match in `<a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<a/>` because in this instance it is the child of another element.

- `/tag1/tag2`

Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

Example: `/a/b` matches the `b` element in the XML fragment `<a>` because it is a child of the root element `a`. It does not have a match in `<a/>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c></c>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><c/>`.

- `//tag`

Matches any instance of `<tag>`.

Example: `//a` matches the `a` element in any of the following: `<a><c/>`; `<c><a>`; `<c><a/></c>`.

`//` can be combined with `/`. For example, `//a/b` matches the `b` element in either of the fragments `<a>` or `<c><a></c>`.

**Note**

`//tag` is the equivalent of `/descendant-or-self::*/*tag`. A common error is to confuse this with `/descendant-or-self::tag`, although the latter expression can actually lead to very different results, as can be seen here:

```
mysql> SET @xml = '<a><b><c>w</c><b>x</b><d>y</d>z</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @xml;
+-----+
| @xml                                     |
+-----+
| <a><b><c>w</c><b>x</b><d>y</d>z</b></a>      |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[1]');
+-----+
| ExtractValue(@xml, '//b[1]')           |
+-----+
| x z                                     |
+-----+
1 row in set (0.00 sec)
```

```

mysql> SELECT ExtractValue(@xml, '//b[2]');
+-----+
| ExtractValue(@xml, '//b[2]') |
+-----+
|                               |
+-----+
1 row in set (0.01 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[1]') |
+-----+
| x z                                             |
+-----+
1 row in set (0.06 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[2]') |
+-----+
|                                               |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[1]') |
+-----+
| z                                             |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[2]') |
+-----+
| x                                             |
+-----+
1 row in set (0.00 sec)

```

- The `*` operator acts as a “wildcard” that matches any element. For example, the expression `*/b` matches the `b` element in either of the XML fragments `<a>` or `<c></c>`. However, the expression does not produce a match in the fragment `<a/>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `*/b/*` will match any child of a `b` element that is itself not the root element.
- You can match any of several locators using the `|` ([UNION](#)) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.
- It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/><c/><b id="idB"/>`. To match against *any* element having `attribute="value"`, use the XPath expression `//*[attribute="value"]`.

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression `//b[@c="x"][@d="y"]` matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have

either of the values 23 or 17, use the expression `//b[@c="23"]|//b[@c="17"]`. You can also use the logical `or` operator for this purpose: `//b[@c="23" or @c="17"]`.

Note

The difference between `or` and `|` is that `or` joins conditions, while `|` joins result sets.

XPath Limitations. The XPath syntax supported by these functions is currently subject to the following limitations:

- Nodeset-to-nodeset comparison (such as `'/a/b[@c=@d]'`) is not supported.
- All of the standard XPath comparison operators are supported. (Bug #22823)
- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```
mysql> SELECT ExtractValue(
->   '<a><b c="1">X</b><b c="2">Y</b></a>',
->   'a/b'
-> ) AS result;
+-----+
| result |
+-----+
| X Y    |
+-----+
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[@c="1"]/d`:

```
mysql> SELECT ExtractValue(
->   '<a>
->     <b c="1"><d>X</d></b>
->     <b c="2"><d>X</d></b>
->   </a>',
->   'a/b/d[../@c="1"]')
-> AS result;
+-----+
| result |
+-----+
| X      |
+-----+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.
- The `::` operator is not supported in combination with node types such as the following:
 - `axis::comment()`
 - `axis::text()`
 - `axis::processing-instructions()`
 - `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::b');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::b') |
```

```

+-----+
| x |
+-----+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::*');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::*') |
+-----+
| x y |
+-----+
1 row in set (0.01 sec)

```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).
- The following XPath functions are not supported, or have known issues as indicated:
 - `id()`
 - `lang()`
 - `local-name()`
 - `name()`
 - `namespace-uri()`
 - `normalize-space()`
 - `starts-with()`
 - `string()`
 - `substring-after()`
 - `substring-before()`
 - `translate()`
- The following axes are not supported:
 - `following-sibling`
 - `following`
 - `preceding-sibling`
 - `preceding`

XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```

mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----+
| ExtractValue(@xml, '//e:f') |
+-----+
| 444 |
+-----+
1 row in set (0.00 sec)

```

```
mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+-----+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+-----+
| <a>111<g:h>555</g:h></a> |
+-----+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by [Apache Xalan](#) and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

Error handling. For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '//&a');
ERROR 1105 (HY000): XPATH syntax error: '&a'
```

If `xml_frag` does not consist of elements which are properly nested and closed, `NULL` is returned and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----+
| ExtractValue('<a>c</a><b', '//a') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
        END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c |
+-----+
1 row in set (0.00 sec)
```

Important

The replacement XML used as the third argument to `UpdateXML()` is *not* checked to determine whether it consists solely of elements which are properly nested and closed.

XPath Injection. *code injection* occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```
<?php
    $file      =   "users.xml";

    $login     =   $_POST["login"];
    $password  =   $_POST["password"];

    $xpath = "//user[login/text()=$login and password/text()=$password]/attribute::id";

    if( file_exists($file) )
    {
        $xml = simplexml_load_file($file);

        if($result = $xml->xpath($xpath))
            echo "You are now logged in as user $result[0].";
        else
            echo "Invalid login name or password.";
    }
    else
        exit("Failed to open $file.");
?>
```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in `$xpath` being evaluated as shown here:

```
//user[login/text()=' or 1=1 and password/text()=' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xpath`, forcing the values passed from a Web form to be converted to strings:

```
$xpath = "//user[login/text()=' $login' and password/text()=' $password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper [Blind XPath Injection](#) (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` function:

```
mysql> SELECT ExtractValue(
->     LOAD_FILE('users.xml'),
```

```

->      '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
-> ) AS id;
+-----+
| id      |
+-----+
| 00327 13579 02403 42354 28570 |
+-----+
1 row in set (0.01 sec)

```

Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```

mysql> SELECT @id = ExtractValue(
->      LOAD_FILE('users.xml'),
->      '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
-> );
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
->      INSTR(@id, ' ') = 0,
->      @id,
->      'Unable to retrieve user ID')
-> AS singleID;
+-----+
| singleID      |
+-----+
| Unable to retrieve user ID |
+-----+
1 row in set (0.00 sec)

```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

12.12 Bit Functions and Operators

Table 12.16 Bit Functions and Operators

| Name | Description |
|--------------------------|--|
| <code>&</code> | Bitwise AND |
| <code>>></code> | Right shift |
| <code><<</code> | Left shift |
| <code>^</code> | Bitwise XOR |
| <code>BIT_COUNT()</code> | Return the number of bits that are set |
| <code> </code> | Bitwise OR |
| <code>~</code> | Bitwise inversion |

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. (`BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` are aggregate functions described at [Section 12.17.1, “Aggregate \(GROUP BY\) Function Descriptions”](#).) Bit functions and operators require `BIGINT` (64-bit integer) arguments and return `BIGINT` values, so they have a maximum range of 64 bits. Arguments of other types (such as the `BINARY` and `VARBINARY` binary string types) are converted to `BIGINT` and truncation might occur.

The following list describes available bit functions and operators:

• |

Bitwise OR.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 29 | 15;
      -> 31
```

• &

Bitwise AND.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 29 & 15;
      -> 13
```

• ^

Bitwise XOR.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 1 ^ 1;
      -> 0
mysql> SELECT 1 ^ 0;
      -> 1
mysql> SELECT 11 ^ 3;
      -> 8
```

• <<

Shifts a longlong (**BIGINT**) number to the left.

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

```
mysql> SELECT 1 << 2;
      -> 4
```

• >>

Shifts a longlong (**BIGINT**) number to the right.

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

```
mysql> SELECT 4 >> 2;
      -> 1
```

• ~

Invert all bits.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 5 & ~1;
      -> 4
```

• BIT_COUNT(N)

Returns the number of bits that are set in the argument *N* as an unsigned 64-bit integer, or **NULL** if the argument is **NULL**.

```
mysql> SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
```

12.13 Encryption and Compression Functions

Table 12.17 Encryption Functions

| Name | Description |
|--|---|
| <code>AES_DECRYPT()</code> | Decrypt using AES |
| <code>AES_ENCRYPT()</code> | Encrypt using AES |
| <code>COMPRESS()</code> | Return result as a binary string |
| <code>DECODE()</code> | Decode a string encrypted using <code>ENCODE()</code> |
| <code>DES_DECRYPT()</code> | Decrypt a string |
| <code>DES_ENCRYPT()</code> | Encrypt a string |
| <code>ENCODE()</code> | Encode a string |
| <code>ENCRYPT()</code> | Encrypt a string |
| <code>MD5()</code> | Calculate MD5 checksum |
| <code>OLD_PASSWORD()</code> | Return the value of the pre-4.1 implementation of <code>PASSWORD</code> |
| <code>PASSWORD()</code> | Calculate and return a password string |
| <code>SHA1()</code> , <code>SHA()</code> | Calculate an SHA-1 160-bit checksum |
| <code>SHA2()</code> | Calculate an SHA-2 checksum |
| <code>UNCOMPRESS()</code> | Uncompress a string compressed |
| <code>UNCOMPRESSED_LENGTH()</code> | Return the length of a string before compression |

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a `VARBINARY` or `BLOB` binary string data type. This will avoid potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (`CHAR`, `VARCHAR`, `TEXT`).

Some encryption functions return strings of ASCII characters: `MD5()`, `OLD_PASSWORD()`, `PASSWORD()`, `SHA()`, `SHA1()`. Their return value is a string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. This is a nonbinary string unless the character set is `binary`.

If an application stores values from a function such as `MD5()` or `SHA1()` that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` and storing the result in a `BINARY(N)` column. Each pair of hexadecimal digits requires one byte in binary form, so the value of `N` depends on the length of the hex string. `N` is 16 for an `MD5()` value and 20 for a `SHA1()` value. For `SHA2()`, `N` ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to eight times if the value is stored in a column that uses the `utf8` character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` string values in a `CHAR(32)` column:

```
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use `UNHEX()` and `BINARY(16)` instead as follows:

```
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES (UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

Note

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as [SHA2\(\)](#).

Caution

Passwords or other sensitive values supplied as arguments to encryption functions are sent as cleartext to the MySQL server unless an SSL connection is used. Also, such values will appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- [AES_DECRYPT\(*crypt_str*,*key_str*\)](#)

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of [AES_ENCRYPT\(\)](#).

- [AES_ENCRYPT\(*str*,*key_str*\)](#)

[AES_ENCRYPT\(\)](#) and [AES_DECRYPT\(\)](#) implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. These functions implement AES with a 128-bit key length, but you can extend them to 256 bits by modifying the source. The key length is a trade off between performance and security.

[AES_ENCRYPT\(\)](#) encrypts the string *str* using the key string *key_str* and returns a binary string containing the encrypted output. [AES_DECRYPT\(\)](#) decrypts the encrypted string *crypt_str* using the key string *key_str* and returns the original plaintext string. If either function argument is `NULL`, the function returns `NULL`.

The *str* and *crypt_str* arguments can be any length, and padding is automatically added to *str* so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the [AES_DECRYPT\(\)](#) function. The length of *crypt_str* can be calculated using this formula:

```
16 * (trunc(string_length / 16) + 1)
```

For a key length of 128 bits, the most secure way to pass a key to the *key_str* argument is to create a truly random 128-bit value and pass it as a binary value. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text',UNHEX('F3229A0B371ED2D9441B830D21A390C3')));
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));
```

Do not pass a password or passphrase directly to *crypt_str*, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

- `COMPRESS(string_to_compress)`

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
-> 21
mysql> SELECT LENGTH(COMPRESS(''));
-> 0
mysql> SELECT LENGTH(COMPRESS('a'));
-> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
-> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra `.` character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)

- `DECODE(encrypt_str,pass_str)`

Decrypts the encrypted string `encrypt_str` using `pass_str` as the password. `encrypt_str` should be a string returned from `ENCODE()`.

- `DES_DECRYPT(encrypt_str[,key_str])`

Decrypts a string encrypted with `DES_ENCRYPT()`. If an error occurs, this function returns `NULL`.

This function works only if MySQL has been configured with SSL support. See [Section 6.3, “Using Encrypted Connections”](#).

If no `key_str` argument is given, `DES_DECRYPT()` examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the `SUPER` privilege. The key file can be specified with the `--des-key-file` server option.

If you pass this function a `key_str` argument, that string is used as the key for decrypting the message.

If the `encrypt_str` argument does not appear to be an encrypted string, MySQL returns the given `encrypt_str`.

- `DES_ENCRYPT(str[, {key_num|key_str}])`

Encrypts the string with the given key using the Triple-DES algorithm.

This function works only if MySQL has been configured with SSL support. See [Section 6.3, “Using Encrypted Connections”](#).

The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()`, if one was given. With no argument, the first key from the DES key file is used. With a `key_num` argument, the

given key number (0 to 9) from the DES key file is used. With a *key_str* argument, the given key string is used to encrypt *str*.

The key file can be specified with the `--des-key-file` server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)`. If an error occurs, `DES_ENCRYPT()` returns `NULL`.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, *key_num* is 127.

The string length for the result is given by this formula:

```
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```
key_num des_key_str
```

Each *key_num* value must be a number in the range from 0 to 9. Lines in the file may be in any order. *des_key_str* is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MySQL to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the `RELOAD` privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

```
mysql> SELECT customer_address FROM customer_table
       > WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

- `ENCODE(str, pass_str)`

Encrypt *str* using *pass_str* as the password. The result is a binary string of the same length as *str*. To decrypt the result, use `DECODE()`.

The `ENCODE()` function should no longer be used. If you still need to use `ENCODE()`, a salt value must be used with it to reduce risk. For example:

```
ENCODE('cleartext', CONCAT('my_random_salt', 'my_secret_password'))
```

A new random salt value must be used whenever a password is updated.

- `ENCRYPT(str[, salt])`

Encrypts *str* using the Unix `crypt()` system call and returns a binary string. The *salt* argument must be a string with at least two characters or the result will be `NULL`. If no *salt* argument is given, a random value is used.

```
mysql> SELECT ENCRYPT('hello');
       -> 'VxuFAJXVARROc'
```

`ENCRYPT()` ignores all but the first eight characters of *str*, at least on some systems. This behavior is determined by the implementation of the underlying `crypt()` system call.

The use of `ENCRYPT()` with the `ucs2`, `utf16`, or `utf32` multibyte character sets is not recommended because the system call expects a string terminated by a zero byte.

If `crypt()` is not available on your system (as is the case with Windows), `ENCRYPT()` always returns `NULL`.

- `MD5(str)`

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```
mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.

- `OLD_PASSWORD(str)`

`OLD_PASSWORD()` was added when the implementation of `PASSWORD()` was changed in MySQL 4.1 to improve security. `OLD_PASSWORD()` returns the value of the pre-4.1 implementation of `PASSWORD()` as a string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to your MySQL server without locking them out. See [Section 6.1.2.4, “Password Hashing in MySQL”](#).

The return value is a string in the connection character set.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided.

- `PASSWORD(str)`

Returns a hashed password string calculated from the cleartext password `str`. The return value is a string in the connection character set, or `NULL` if the argument is `NULL`. This function is the SQL interface to the algorithm used by the server to encrypt MySQL passwords for storage in the `mysql.user` grant table.

The `old_passwords` system variable controls the password hashing method used by the `PASSWORD()` function. It also influences password hashing performed by `CREATE USER` and `GRANT` statements that specify a password using an `IDENTIFIED BY` clause.

The following table shows, for each password hashing method, the permitted value of `old_passwords` and which authentication plugins use the hashing method.

| Password Hashing Method | old_passwords Value | Associated Authentication Plugin |
|--------------------------|---------------------|------------------------------------|
| MySQL 4.1 native hashing | 0 or OFF | <code>mysql_native_password</code> |
| Pre-4.1 (“old”) hashing | 1 or ON | <code>mysql_old_password</code> |

If `old_passwords=1`, `PASSWORD(str)` returns the same value as `OLD_PASSWORD(str)`. The latter function is not affected by the value of `old_passwords`.

```
mysql> SET old_passwords = 0;
mysql> SELECT PASSWORD('mypass'), OLD_PASSWORD('mypass');
+-----+-----+
| PASSWORD('mypass') | OLD_PASSWORD('mypass') |
+-----+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 | 6f8c114b58f2ce9e |
+-----+-----+
```

```
mysql> SET old_passwords = 1;
```

```
mysql> SELECT PASSWORD('mypass'), OLD_PASSWORD('mypass');
+-----+-----+
| PASSWORD('mypass') | OLD_PASSWORD('mypass') |
+-----+-----+
| 6f8c114b58f2ce9e   | 6f8c114b58f2ce9e     |
+-----+-----+
```

Encryption performed by `PASSWORD()` is one-way (not reversible). It is not the same type of encryption as used for Unix passwords; for that, use `ENCRYPT()`.

Note

`PASSWORD()` is used by the authentication system in MySQL Server; you should *not* use it in your own applications. For that purpose, consider a more secure function such as `AES_ENCRYPT()` or `SHA2()` instead. Also see [RFC 2195, section 2 \(Challenge-Response Authentication Mechanism \(CRAM\)\)](#), for more information about handling passwords and authentication securely in your applications.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided.

Caution

Statements that invoke `PASSWORD()` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Client Logging”](#).

- `SHA1(str), SHA(str)`

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or `NULL` if the argument was `NULL`. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. `SHA()` is synonymous with `SHA1()`.

The return value is a string in the connection character set.

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

`SHA1()` can be considered a cryptographically more secure equivalent of `MD5()`. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- `SHA2(str, hash_length)`

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the plaintext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is `NULL` or the hash length is not one of the permitted values, the return value is `NULL`. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```
mysql> SELECT SHA2('abc', 224);
```

```
-> '23097d223405d8228642a477bda255b32aadfce4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See [Section 6.3, “Using Encrypted Connections”](#).

`SHA2()` can be considered cryptographically more secure than `MD5()` or `SHA1()`.

- `UNCOMPRESS(string_to_uncompress)`

Uncompresses a string compressed by the `COMPRESS()` function. If the argument is not a compressed value, the result is `NULL`. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- `UNCOMPRESSED_LENGTH(compressed_string)`

Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

12.14 Locking Functions

This section describes functions used to manipulate user-level locks.

Table 12.18 Locking Functions

| Name | Description |
|-----------------------------|--|
| <code>GET_LOCK()</code> | Get a named lock |
| <code>IS_FREE_LOCK()</code> | Whether the named lock is free |
| <code>IS_USED_LOCK()</code> | Whether the named lock is in use; return connection identifier if true |
| <code>RELEASE_LOCK()</code> | Release the named lock |

- `GET_LOCK(str, timeout)`

Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. A negative `timeout` value means infinite timeout.

Returns `1` if the lock was obtained successfully, `0` if the attempt timed out (for example, because another client has previously locked the name), or `NULL` if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

Important

The behavior of `GET_LOCK()` changes in MySQL 5.7. In consideration of future upgrades, limit the `str` value to 64 characters or less and do not rely on subsequent calls to `GET_LOCK()` releasing previous locks.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also

enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

```
mysql> SELECT GET_LOCK('lock1',10);
-> 1
mysql> SELECT IS_FREE_LOCK('lock2');
-> 1
mysql> SELECT GET_LOCK('lock2',10);
-> 1
mysql> SELECT RELEASE_LOCK('lock2');
-> 1
mysql> SELECT RELEASE_LOCK('lock1');
-> NULL
```

The second `RELEASE_LOCK()` call returns `NULL` because the lock `'lock1'` was automatically released by the second `GET_LOCK()` call.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined. Applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `IS_FREE_LOCK(str)`

Checks whether the lock named `str` is free to use (that is, not locked). Returns `1` if the lock is free (no one is using the lock), `0` if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `IS_USED_LOCK(str)`

Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `RELEASE_LOCK(str)`

Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns `1` if the lock was released, `0` if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()`. See [Section 13.2.3, “DO Statement”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

12.15 Information Functions

Table 12.19 Information Functions

| Name | Description |
|--------------------------|--|
| <code>BENCHMARK()</code> | Repeatedly execute an expression |
| <code>CHARSET()</code> | Return the character set of the argument |

| Name | Description |
|---|---|
| <code>COERCIBILITY()</code> | Return the collation coercibility value of the string argument |
| <code>COLLATION()</code> | Return the collation of the string argument |
| <code>CONNECTION_ID()</code> | Return the connection ID (thread ID) for the connection |
| <code>CURRENT_USER()</code> , <code>CURRENT_USER</code> | The authenticated user name and host name |
| <code>DATABASE()</code> | Return the default (current) database name |
| <code>FOUND_ROWS()</code> | For a <code>SELECT</code> with a <code>LIMIT</code> clause, the number of rows that would be returned were there no <code>LIMIT</code> clause |
| <code>LAST_INSERT_ID()</code> | Value of the <code>AUTOINCREMENT</code> column for the last <code>INSERT</code> |
| <code>ROW_COUNT()</code> | The number of rows updated |
| <code>SCHEMA()</code> | Synonym for <code>DATABASE()</code> |
| <code>SESSION_USER()</code> | Synonym for <code>USER()</code> |
| <code>SYSTEM_USER()</code> | Synonym for <code>USER()</code> |
| <code>USER()</code> | The user name and host name provided by the client |
| <code>VERSION()</code> | Return a string that indicates the MySQL server version |

- `BENCHMARK(count, expr)`

The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is 0, or `NULL` for inappropriate arguments such as a `NULL` or negative repeat count.

The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000,AES_ENCRYPT('hello','goodbye'));
+-----+
| BENCHMARK(1000000,AES_ENCRYPT('hello','goodbye')) |
+-----+
|                                                    0 |
+-----+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

`BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` will fail if the table `t` has more than one column or more than one row.
- Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.
- `CHARSET(str)`

Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
-> 'latin1'
mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
-> 'utf8'
mysql> SELECT CHARSET(USER());
-> 'utf8'
```

- `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(USER());
-> 3
mysql> SELECT COERCIBILITY('abc');
-> 4
mysql> SELECT COERCIBILITY(1000);
-> 5
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

| Coercibility | Meaning | Example |
|--------------|--------------------|---|
| 0 | Explicit collation | Value with <code>COLLATE</code> clause |
| 1 | No collation | Concatenation of strings with different collations |
| 2 | Implicit collation | Column value, stored routine parameter or local variable |
| 3 | System constant | <code>USER()</code> return value |
| 4 | Coercible | Literal string |
| 5 | Numeric | Numeric or temporal value |
| 5 | Ignorable | <code>NULL</code> or an expression derived from <code>NULL</code> |

For more information, see [Section 10.8.4, “Collation Coercibility in Expressions”](#).

- `COLLATION(str)`

Returns the collation of the string argument.

```
mysql> SELECT COLLATION('abc');
-> 'latin1_swedish_ci'
mysql> SELECT COLLATION(_utf8'abc');
-> 'utf8_general_ci'
```

- `CONNECTION_ID()`

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

The value returned by `CONNECTION_ID()` is the same type of value as displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table.

```
mysql> SELECT CONNECTION_ID();
-> 23786
```

- `CURRENT_USER`, `CURRENT_USER()`

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8` character set.

The value of `CURRENT_USER()` can differ from the value of `USER()`.

```
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see [Section 17.4.1.8, "Replication of `CURRENT_USER\(\)`"](#).

- `DATABASE()`

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`.

- `FOUND_ROWS()`

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include an `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
-> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display

containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

Important

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a 64-bit value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value has a type of `BIGINT UNSIGNED` as of MySQL 5.5.29, `BIGINT` (signed) before that. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer as of MySQL 5.5.29, a signed integer before that.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()`

is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Prior to MySQL 5.5.35, this function was not replicated correctly if replication filtering rules were in use. (Bug #17234370, Bug #69861)

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column *by that client*. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

Important

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```
mysql> USE test;

mysql> CREATE TABLE t (
  id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
  name VARCHAR(10) NOT NULL
);

mysql> INSERT INTO t VALUES (NULL, 'Bob');

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
+----+-----+

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                  1 |
+-----+

mysql> INSERT INTO t VALUES
  (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
```

```

+-----+
| 1 | Bob |
| 2 | Mary |
| 3 | Jane |
| 4 | Lisa |
+-----+

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                2 |
+-----+

```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was `2`, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or `0` is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to `1` or `2`, as demonstrated in the following example:

```

mysql> USE test;

mysql> SELECT @@innodb_autoinc_lock_mode;
+-----+
| @@innodb_autoinc_lock_mode |
+-----+
|                            1 |
+-----+

mysql> CREATE TABLE `t` (
  `id` INT(11) NOT NULL AUTO_INCREMENT,
  `val` INT(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

# Insert two rows

mysql> INSERT INTO t (val) VALUES (1),(2);

# With auto_increment_offset=1, the inserted rows
# result in an AUTO_INCREMENT value of 3

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=latin1

# LAST_INSERT_ID() returns the first automatically generated
# value that is successfully inserted for the AUTO_INCREMENT column

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+

# The attempted insertion of duplicate rows fail but errors are ignored

mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);

```

```

Query OK, 0 rows affected (0.00 sec)
Records: 2 Duplicates: 2 Warnings: 0

# With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter
# is incremented for the ignored rows

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=5 DEFAULT CHARSET=latin1

# The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+

```

For more information, see [Section 14.9.1.4, “AUTO_INCREMENT Handling in InnoDB”](#).

If *expr* is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```

mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);

```

2. Use the table to generate sequence numbers like this:

```

mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();

```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See [Section 23.7.6.37, “mysql_insert_id\(\)”](#).

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- `ROW_COUNT()`

`ROW_COUNT()` returns a value as follows:

- DDL statements: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
- DML statements other than `SELECT`: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA`.
- `SELECT`: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1`, `ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` returns the number of rows written to the file.
- `SIGNAL` statements: 0.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The `ROW_COUNT()` value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|           3 |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|           2 |
+-----+
1 row in set (0.00 sec)
```

Important

`ROW_COUNT()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `SCHEMA()`

This function is a synonym for `DATABASE()`.

- `SESSION_USER()`

`SESSION_USER()` is a synonym for `USER()`.

- `SYSTEM_USER()`

`SYSTEM_USER()` is a synonym for `USER()`.

- `USER()`

Returns the current MySQL user name and host name as a string in the `utf8` character set.

```
mysql> SELECT USER();
-> 'david@localhost'
```

The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of `CURRENT_USER()`.

- `VERSION()`

Returns a string that indicates the MySQL server version. The string uses the `utf8` character set. The value might have a suffix in addition to the version number. See the description of the `version` system variable in [Section 5.1.7, “Server System Variables”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT VERSION();
-> '5.5.62-standard'
```

12.16 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see [Section 11.4, “Spatial Data Types”](#).

12.16.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

Table 12.20 Spatial Functions

| Name | Description |
|--|---|
| <code>Area()</code> | Return Polygon or MultiPolygon area |
| <code>AsBinary()</code> , <code>AsWKB()</code> | Convert from internal geometry format to WKB |
| <code>AsText()</code> , <code>AsWKT()</code> | Convert from internal geometry format to WKT |
| <code>Centroid()</code> | Return centroid as a point |
| <code>Contains()</code> | Whether MBR of one geometry contains MBR of another |
| <code>Crosses()</code> | Whether one geometry crosses another |

| Name | Description |
|--|--|
| <code>Dimension()</code> | Dimension of geometry |
| <code>Disjoint()</code> | Whether MBRs of two geometries are disjoint |
| <code>EndPoint()</code> | End Point of LineString |
| <code>Envelope()</code> | Return MBR of geometry |
| <code>Equals()</code> | Whether MBRs of two geometries are equal |
| <code>ExteriorRing()</code> | Return exterior ring of Polygon |
| <code>GeomCollFromText()</code> , <code>GeometryCollectionFromText()</code> | Return geometry collection from WKT |
| <code>GeomCollFromWKB()</code> , <code>GeometryCollectionFromWKB()</code> | Return geometry collection from WKB |
| <code>GeometryCollection()</code> | Construct geometry collection from geometries |
| <code>GeometryN()</code> | Return N-th geometry from geometry collection |
| <code>GeometryType()</code> | Return name of geometry type |
| <code>GeomFromText()</code> , <code>GeometryFromText()</code> | Return geometry from WKT |
| <code>GeomFromWKB()</code> , <code>GeometryFromWKB()</code> | Return geometry from WKB |
| <code>GLength()</code> | Return length of LineString |
| <code>InteriorRingN()</code> | Return N-th interior ring of Polygon |
| <code>Intersects()</code> | Whether MBRs of two geometries intersect |
| <code>IsClosed()</code> | Whether a geometry is closed and simple |
| <code>IsEmpty()</code> | Placeholder function |
| <code>IsSimple()</code> | Whether a geometry is simple |
| <code>LineFromText()</code> , <code>LineStringFromText()</code> | Construct LineString from WKT |
| <code>LineFromWKB()</code> , <code>LineStringFromWKB()</code> | Construct LineString from WKB |
| <code>LineString()</code> | Construct LineString from Point values |
| <code>MBRContains()</code> | Whether MBR of one geometry contains MBR of another |
| <code>MBRDisjoint()</code> | Whether MBRs of two geometries are disjoint |
| <code>MBREqual()</code> | Whether MBRs of two geometries are equal |
| <code>MBRIntersects()</code> | Whether MBRs of two geometries intersect |
| <code>MBROverlaps()</code> | Whether MBRs of two geometries overlap |
| <code>MBRTouches()</code> | Whether MBRs of two geometries touch |
| <code>MBRWithin()</code> | Whether MBR of one geometry is within MBR of another |
| <code>MLineFromText()</code> , <code>MultiLineStringFromText()</code> | Construct MultiLineString from WKT |
| <code>MLineFromWKB()</code> , <code>MultiLineStringFromWKB()</code> | Construct MultiLineString from WKB |
| <code>MPointFromText()</code> , <code>MultiPointFromText()</code> | Construct MultiPoint from WKT |
| <code>MPointFromWKB()</code> , <code>MultiPointFromWKB()</code> | Construct MultiPoint from WKB |

| Name | Description |
|---|--|
| <code>MPolyFromText()</code> , <code>MultiPolygonFromText()</code> | Construct MultiPolygon from WKT |
| <code>MPolyFromWKB()</code> , <code>MultiPolygonFromWKB()</code> | Construct MultiPolygon from WKB |
| <code>MultiLineString()</code> | Construct MultiLineString from LineString values |
| <code>MultiPoint()</code> | Construct MultiPoint from Point values |
| <code>MultiPolygon()</code> | Construct MultiPolygon from Polygon values |
| <code>NumGeometries()</code> | Return number of geometries in geometry collection |
| <code>NumInteriorRings()</code> | Return number of interior rings in Polygon |
| <code>NumPoints()</code> | Return number of points in LineString |
| <code>Overlaps()</code> | Whether MBRs of two geometries overlap |
| <code>Point()</code> | Construct Point from coordinates |
| <code>PointFromText()</code> | Construct Point from WKT |
| <code>PointFromWKB()</code> | Construct Point from WKB |
| <code>PointN()</code> | Return N-th point from LineString |
| <code>PolyFromText()</code> , <code>PolygonFromText()</code> | Construct Polygon from WKT |
| <code>PolyFromWKB()</code> , <code>PolygonFromWKB()</code> | Construct Polygon from WKB |
| <code>Polygon()</code> | Construct Polygon from LineString arguments |
| <code>SRID()</code> | Return spatial reference system ID for geometry |
| <code>StartPoint()</code> | Start Point of LineString |
| <code>Touches()</code> | Whether one geometry touches another |
| <code>Within()</code> | Whether MBR of one geometry is within MBR of another |
| <code>X()</code> | Return X coordinate of Point |
| <code>Y()</code> | Return Y coordinate of Point |

12.16.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described at [Section 11.4.2.2, “Geometry Class”](#). The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional argument-handling characteristics, as discussed in the sections where those function descriptions occur.

Spatial functions are defined only for valid geometry values. If an invalid geometry is passed to a spatial function, the result is undefined.

The spatial reference identifier (SRID) of a geometry identifies the coordinate space in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32}-1$. If a larger value is given, only the lower 32 bits are used.

Geometry values produced by any spatial function inherit the SRID of the geometry arguments.

12.16.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromText()` accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

For a description of WKT format, see [Well-Known Text \(WKT\) Format](#).

- `GeomCollFromText(wkt[, srid]), GeometryCollectionFromText(wkt[, srid])`
Constructs a `GeometryCollection` value using its WKT representation and SRID.
- `GeomFromText(wkt[, srid]), GeometryFromText(wkt[, srid])`
Constructs a geometry value of any type using its WKT representation and SRID.
- `LineFromText(wkt[, srid]), LineStringFromText(wkt[, srid])`
Constructs a `LineString` value using its WKT representation and SRID.
- `MLineFromText(wkt[, srid]), MultiLineStringFromText(wkt[, srid])`
Constructs a `MultiLineString` value using its WKT representation and SRID.
- `MPointFromText(wkt[, srid]), MultiPointFromText(wkt[, srid])`
Constructs a `MultiPoint` value using its WKT representation and SRID.
- `MPolyFromText(wkt[, srid]), MultiPolygonFromText(wkt[, srid])`
Constructs a `MultiPolygon` value using its WKT representation and SRID.
- `PointFromText(wkt[, srid])`
Constructs a `Point` value using its WKT representation and SRID.
- `PolyFromText(wkt[, srid]), PolygonFromText(wkt[, srid])`
Constructs a `Polygon` value using its WKT representation and SRID.

12.16.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a `BLOB` containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromWKB()` accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

These functions also accept geometry objects as returned by the functions in [Section 12.16.5, "MySQL-Specific Functions That Create Geometry Values"](#). Thus, those functions may be used to provide the first argument to the functions in this section.

For a description of WKB format, see [Well-Known Binary \(WKB\) Format](#).

- `GeomCollFromWKB(wkb[, srid]), GeometryCollectionFromWKB(wkb[, srid])`
Constructs a `GeometryCollection` value using its WKB representation and SRID.
- `GeomFromWKB(wkb[, srid]), GeometryFromWKB(wkb[, srid])`
Constructs a geometry value of any type using its WKB representation and SRID.
- `LineFromWKB(wkb[, srid]), LineStringFromWKB(wkb[, srid])`
Constructs a `LineString` value using its WKB representation and SRID.
- `MLineFromWKB(wkb[, srid]), MultiLineStringFromWKB(wkb[, srid])`
Constructs a `MultiLineString` value using its WKB representation and SRID.
- `MPointFromWKB(wkb[, srid]), MultiPointFromWKB(wkb[, srid])`

Constructs a `MultiPoint` value using its WKB representation and SRID.

- `MPolyFromWKB(wkb[, srid]), MultiPolygonFromWKB(wkb[, srid])`

Constructs a `MultiPolygon` value using its WKB representation and SRID.

- `PointFromWKB(wkb[, srid])`

Constructs a `Point` value using its WKB representation and SRID.

- `PolyFromWKB(wkb[, srid]), PolygonFromWKB(wkb[, srid])`

Constructs a `Polygon` value using its WKB representation and SRID.

12.16.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is `NULL`.

For example, you can insert the geometry return value from `Point()` directly into a `POINT` column:

```
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- `GeometryCollection(g [, g] ...)`

Constructs a `GeometryCollection` value from the geometry arguments.

If an argument contains a nonsupported geometry, the return value is `NULL`.

- `LineString(pt [, pt] ...)`

Constructs a `LineString` value from a number of `Point` or WKB `Point` arguments. If the number of arguments is less than two, the return value is `NULL`.

- `MultiLineString(ls [, ls] ...)`

Constructs a `MultiLineString` value using `LineString` or WKB `LineString` arguments.

- `MultiPoint(pt [, pt2] ...)`

Constructs a `MultiPoint` value using `Point` or WKB `Point` arguments.

- `MultiPolygon(poly [, poly] ...)`

Constructs a `MultiPolygon` value from a set of `Polygon` or WKB `Polygon` arguments.

- `Point(x, y)`

Constructs a `Point` using its coordinates.

- `Polygon(ls [, ls] ...)`

Constructs a `Polygon` value from a number of `LineString` or WKB `LineString` arguments. If any argument does not represent a `LinearRing` (that is, not a closed and simple `LineString`), the return value is `NULL`.

12.16.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See [Section 12.16.3, “Functions That Create Geometry Values from WKT Values”](#), and [Section 12.16.4, “Functions That Create Geometry Values from WKB Values”](#).

- `AsBinary(g)`, `AsWKB(g)`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

The result is `NULL` if the geometry argument is `NULL` or not a syntactically well-formed geometry.

```
SELECT AsBinary(g) FROM geom;
```

- `AsText(g)`, `AsWKT(g)`

Converts a value in internal geometry format to its WKT representation and returns the string result.

The result is `NULL` if the geometry argument is `NULL` or not a syntactically well-formed geometry.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
+-----+
| AsText(GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

12.16.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, the `Area()` polygon function returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

12.16.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- `Dimension(g)`

Returns the inherent dimension of the geometry value *g*. The result can be -1, 0, 1, or 2. The meaning of these values is given in [Section 11.4.2.2, “Geometry Class”](#).

```
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- `Envelope(g)`

Returns the minimum bounding rectangle (MBR) for the geometry value *g*. The result is returned as a `Polygon` value that is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-----+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)'))) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

- `GeometryType(g)`

Returns a binary string indicating the name of the geometry type of which the geometry instance *g* is a member. The name corresponds to one of the instantiable [Geometry](#) subclasses.

```
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+-----+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----+
| POINT |
+-----+
```

- [IsEmpty\(*g*\)](#)

This function is a placeholder that returns 0 for any valid geometry value, 1 for any invalid geometry value or [NULL](#).

MySQL does not support GIS [EMPTY](#) values such as [POINT EMPTY](#).

- [IsSimple\(*g*\)](#)

In MySQL 5.5, this function is a placeholder that always returns 0.

The descriptions of the instantiable geometric classes given under [Section 11.4.2, “The OpenGIS Geometry Model”](#) includes the specific conditions that cause class instances to be classified as not simple.

- [SRID\(*g*\)](#)

Returns an integer indicating the spatial reference system ID associated with the geometry value *g*.

```
mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+-----+
| 101 |
+-----+
```

12.16.7.2 Point Property Functions

A [Point](#) consists of X and Y coordinates, which may be obtained using the following functions:

- [X\(*p*\)](#)

Returns the X-coordinate value for the [Point](#) object *p* as a double-precision number.

```
mysql> SELECT X(Point(56.7, 53.34));
+-----+
| X(Point(56.7, 53.34)) |
+-----+
| 56.7 |
+-----+
```

- [Y\(*p*\)](#)

Returns the Y-coordinate value for the [Point](#) object *p* as a double-precision number.

```
mysql> SELECT Y(Point(56.7, 53.34));
+-----+
| Y(Point(56.7, 53.34)) |
+-----+
| 53.34 |
+-----+
```

12.16.7.3 LineString and MultiLineString Property Functions

A [LineString](#) consists of [Point](#) values. You can extract particular points of a [LineString](#), count the number of points that it contains, or obtain its length.

Some functions in this section also work for `MultiLineString` values.

- `EndPoint(ls)`

Returns the `Point` that is the endpoint of the `LineString` value `ls`. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- `GLength(ls)`

Returns a double-precision number indicating the length of the `LineString` or `MultiLineString` value `ls` in its associated spatial reference. The length of a `MultiLineString` value is equal to the sum of the lengths of its elements. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+-----+
| GLength(GeomFromText(@ls)) |
+-----+
| 2.8284271247461903 |
+-----+

mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@mls));
+-----+
| GLength(GeomFromText(@mls)) |
+-----+
| 4.242640687119286 |
+-----+
```

`GLength()` is a nonstandard name. It corresponds to the OpenGIS `Length()` function. (There is an existing SQL function `Length()` that calculates the length of string values.)

- `IsClosed(ls)`

For a `LineString` value `ls`, `IsClosed()` returns 1 if `ls` is closed (that is, its `StartPoint()` and `EndPoint()` values are the same). If the argument is `NULL` or an empty geometry, the return value is `NULL`.

For a `MultiLineString` value `ls`, `IsClosed()` returns 1 if `ls` is closed (that is, the `StartPoint()` and `EndPoint()` values are the same for each `LineString` in `ls`).

`IsClosed()` returns 0 if `ls` is not closed.

```
mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';

mysql> SELECT IsClosed(GeomFromText(@ls1));
+-----+
| IsClosed(GeomFromText(@ls1)) |
+-----+
| 0 |
+-----+

mysql> SELECT IsClosed(GeomFromText(@ls2));
+-----+
| IsClosed(GeomFromText(@ls2)) |
+-----+
| 1 |
+-----+
```

```
mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5));'
mysql> SELECT IsClosed(GeomFromText(@ls3));
+-----+
| IsClosed(GeomFromText(@ls3)) |
+-----+
|                               0 |
+-----+
```

- `NumPoints(ls)`

Returns the number of `Point` objects in the `LineString` value `ls`. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT NumPoints(GeomFromText(@ls));
+-----+
| NumPoints(GeomFromText(@ls)) |
+-----+
|                               3 |
+-----+
```

- `PointN(ls, N)`

Returns the `N`-th `Point` in the `LineString` value `ls`. Points are numbered beginning with 1. If any argument is `NULL` or the geometry argument is an empty geometry, the return value is `NULL`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(PointN(GeomFromText(@ls),2));
+-----+
| AsText(PointN(GeomFromText(@ls),2)) |
+-----+
| POINT(2 2)                          |
+-----+
```

- `StartPoint(ls)`

Returns the `Point` that is the start point of the `LineString` value `ls`. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(StartPoint(GeomFromText(@ls)));
+-----+
| AsText(StartPoint(GeomFromText(@ls))) |
+-----+
| POINT(1 1)                            |
+-----+
```

12.16.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of `Polygon` or `MultiPolygon` values.

- `Area({poly|mpoly})`

Returns a double-precision number indicating the area of the `Polygon` or `MultiPolygon` argument, as measured in its spatial reference system. For arguments of dimension 0 or 1, the result is 0. If the argument is an empty geometry the return value is 0. If the argument is `NULL` the return value is `NULL`.

```
mysql> SET @poly =
'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1));'
mysql> SELECT Area(GeomFromText(@poly));
+-----+
| Area(GeomFromText(@poly)) |
+-----+
|                               4 |
+-----+
```

```
mysql> SET @mpoly =
      'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
+-----+
| Area(GeomFromText(@mpoly)) |
+-----+
|                               8 |
+-----+
```

- `Centroid({poly|mpoly})`

Returns the mathematical centroid for the `Polygon` or `MultiPolygon` argument as a `Point`. The result is not guaranteed to be on the argument. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```
mysql> SET @poly =
      GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 5))');
mysql> SELECT GeometryType(@poly),AsText(Centroid(@poly));
+-----+-----+
| GeometryType(@poly) | AsText(Centroid(@poly)) |
+-----+-----+
| POLYGON              | POINT(4.958333333333333 4.958333333333333) |
+-----+-----+
```

- `ExteriorRing(poly)`

Returns the exterior ring of the `Polygon` value `poly` as a `LineString`. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```
mysql> SET @poly =
      'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+-----+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0)           |
+-----+
```

- `InteriorRingN(poly, N)`

Returns the `N`-th interior ring for the `Polygon` value `poly` as a `LineString`. Rings are numbered beginning with 1. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```
mysql> SET @poly =
      'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+-----+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1)             |
+-----+
```

- `NumInteriorRings(poly)`

Returns the number of interior rings in the `Polygon` value `poly`. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```
mysql> SET @poly =
      'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT NumInteriorRings(GeomFromText(@poly));
+-----+
| NumInteriorRings(GeomFromText(@poly)) |
+-----+
|                               1 |
+-----+
```

12.16.7.5 GeometryCollection Property Functions

These functions return properties of `GeometryCollection` values.

- `GeometryN(gc, N)`

Returns the *N*-th geometry in the `GeometryCollection` value *gc*. Geometries are numbered beginning with 1. If any argument is `NULL` or the geometry argument is an empty geometry, the return value is `NULL`.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT AsText(GeometryN(GeomFromText(@gc),1));
+-----+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+-----+
| POINT(1 1) |
+-----+
```

- `NumGeometries(gc)`

Returns the number of geometries in the `GeometryCollection` value *gc*. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT NumGeometries(GeomFromText(@gc));
+-----+
| NumGeometries(GeomFromText(@gc)) |
+-----+
| 2 |
+-----+
```

12.16.8 Spatial Operator Functions

Section 12.16.7, “Geometry Property Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `Envelope(g)`
- `StartPoint(ls)`
- `EndPoint(ls)`
- `PointN(ls, N)`
- `ExteriorRing(poly)`
- `InteriorRingN(poly, N)`
- `GeometryN(gc, N)`

12.16.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

There is also a MySQL-specific set of MBR-based functions available to test the relationship between two geometry values.

12.16.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values *g1* and *g2*, using precise object shapes. The return values 1 and 0 indicate true and false, respectively.

- `Crosses(g1, g2)`

The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect.
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries.
- Their intersection is not equal to either of the two given geometries.

This function returns 1 or 0 to indicate whether *g1* spatially crosses *g2*. If *g1* is a `Polygon` or a `MultiPolygon`, or if *g2* is a `Point` or a `MultiPoint`, the return value is `NULL`.

- `Touches(g1, g2)`

Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether *g1* spatially touches *g2*.

12.16.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries *g1* and *g2*. The return values 1 and 0 indicate true and false, respectively.

A corresponding set of MBR functions defined according to the OpenGIS specification is described later in this section.

- `MBRContains(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* contains the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRWithin()`.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRWithin(@g2,@g1);
+-----+-----+
| MBRContains(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+-----+
| 1 | 1 |
+-----+-----+
```

- `MBRDisjoint(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* are disjoint (do not intersect).

- `MBREqual(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* are the same.

- `MBRIntersects(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* intersect.

- `MBROverlaps(g1, g2)`

Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* overlap.

- `MBRTouches(g1, g2)`

Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* touch.

- `MBRWithin(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* is within the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRContains()`.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+-----+-----+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

The OpenGIS specification defines the following functions that test the relationship between two geometry values *g1* and *g2*. The MySQL implementation uses minimum bounding rectangles, so these functions return the same result as the corresponding MBR-based functions described earlier in this section. The return values 1 and 0 indicate true and false, respectively.

- `Contains(g1, g2)`

Returns 1 or 0 to indicate whether *g1* completely contains *g2*. This tests the opposite relationship as `Within()`.

- `Disjoint(g1, g2)`

Returns 1 or 0 to indicate whether *g1* is spatially disjoint from (does not intersect) *g2*.

- `Equals(g1, g2)`

Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.

- `Intersects(g1, g2)`

Returns 1 or 0 to indicate whether *g1* spatially intersects *g2*.

- `Overlaps(g1, g2)`

Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether *g1* spatially overlaps *g2*.

- `Within(g1, g2)`

Returns 1 or 0 to indicate whether *g1* is spatially within *g2*. This tests the opposite relationship as `Contains()`.

12.17 Aggregate (GROUP BY) Functions

12.17.1 Aggregate (GROUP BY) Function Descriptions

This section describes group (aggregate) functions that operate on sets of values.

Table 12.21 Aggregate (GROUP BY) Functions

| Name | Description |
|---------------------------------|--|
| AVG() | Return the average value of the argument |
| BIT_AND() | Return bitwise AND |
| BIT_OR() | Return bitwise OR |
| BIT_XOR() | Return bitwise XOR |
| COUNT() | Return a count of the number of rows returned |
| COUNT(DISTINCT) | Return the count of a number of different values |
| GROUP_CONCAT() | Return a concatenated string |
| MAX() | Return the maximum value |
| MIN() | Return the minimum value |
| STD() | Return the population standard deviation |
| STDDEV() | Return the population standard deviation |
| STDDEV_POP() | Return the population standard deviation |
| STDDEV_SAMP() | Return the sample standard deviation |
| SUM() | Return the sum |
| VAR_POP() | Return the population standard variance |
| VAR_SAMP() | Return the sample variance |
| VARIANCE() | Return the population standard variance |

Unless otherwise stated, group functions ignore `NULL` values.

If you use a group function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows. For more information, see [Section 12.17.3, “MySQL Handling of GROUP BY”](#).

For numeric arguments, the variance and standard deviation functions return a `DOUBLE` value. The [SUM\(\)](#) and [AVG\(\)](#) functions return a `DECIMAL` value for exact-value arguments (integer or `DECIMAL`), and a `DOUBLE` value for approximate-value arguments (`FLOAT` or `DOUBLE`).

The [SUM\(\)](#) and [AVG\(\)](#) aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value.

Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as [SUM\(\)](#) or [AVG\(\)](#) that expect a numeric argument cast the argument to a number if necessary. For `SET` or `ENUM` values, the cast operation causes the underlying numeric value to be used.

The [BIT_AND\(\)](#), [BIT_OR\(\)](#), and [BIT_XOR\(\)](#) aggregate functions perform bit operations. They require `BIGINT` (64-bit integer) arguments and return `BIGINT` values. Arguments of other types are converted to `BIGINT` and truncation might occur.

- [AVG\(\[DISTINCT\] *expr*\)](#)

Returns the average value of *expr*. The `DISTINCT` option can be used to return the average of the distinct values of *expr*.

If there are no matching rows, [AVG\(\)](#) returns `NULL`.

```
mysql> SELECT student_name, AVG(test_score)
```

```
FROM student
GROUP BY student_name;
```

- `BIT_AND(expr)`

Returns the bitwise `AND` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

If there are no matching rows, `BIT_AND()` returns a neutral value (all bits set to 1).

- `BIT_OR(expr)`

Returns the bitwise `OR` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

If there are no matching rows, `BIT_OR()` returns a neutral value (all bits set to 0).

- `BIT_XOR(expr)`

Returns the bitwise `XOR` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

If there are no matching rows, `BIT_XOR()` returns a neutral value (all bits set to 0).

- `COUNT(expr)`

Returns a count of the number of non-`NULL` values of *expr* in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value.

If there are no matching rows, `COUNT()` returns 0.

```
mysql> SELECT student.student_name,COUNT(*)
FROM student,course
WHERE student.student_id=course.student_id
GROUP BY student_name;
```

`COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain `NULL` values.

For transactional storage engines such as `InnoDB`, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

`InnoDB` does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

To process a `SELECT COUNT(*)` statement, `InnoDB` scans an index of the table, which takes some time if the index is not entirely in the buffer pool. For a faster count, create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use `SHOW TABLE STATUS`.

`InnoDB` handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

For `MyISAM` tables, `COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to `MyISAM` tables, because an exact row count is stored for this storage engine and can be accessed very quickly. `COUNT(1)` is only subject to the same optimization if the first column is defined as `NOT NULL`.

- `COUNT(DISTINCT expr, [expr...])`

Returns a count of the number of rows with different non-NULL *expr* values.

If there are no matching rows, `COUNT(DISTINCT)` returns 0.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain NULL by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.

- `GROUP_CONCAT(expr)`

This function returns a string result with the concatenated non-NULL values from a group. It returns NULL if there are no non-NULL values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
              [ASC | DESC] [,col_name ...]]
             [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
           GROUP_CONCAT(test_score)
        FROM student
        GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
           GROUP_CONCAT(DISTINCT test_score
                       ORDER BY test_score DESC SEPARATOR ' ')
        FROM student
        GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the `DISTINCT` clause. To sort values in the result, use the `ORDER BY` clause. To sort in reverse order, add the `DESC` (descending) keyword to the name of the column you are sorting by in the `ORDER BY` clause. The default is ascending order; this may be specified explicitly using the `ASC` keyword. The default separator between values in a group is comma (,). To specify a separator explicitly, use `SEPARATOR` followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify `SEPARATOR ''`.

The result is truncated to the maximum length that is given by the `group_concat_max_len` system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of `max_allowed_packet`. The syntax to change the value of `group_concat_max_len` at runtime is as follows, where *val* is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is `TEXT` or `BLOB` unless `group_concat_max_len` is less than or equal to 512, in which case the result type is `VARCHAR` or `VARBINARY`.

See also `CONCAT()` and `CONCAT_WS()`: [Section 12.7, “String Functions and Operators”](#).

- `MAX([DISTINCT] expr)`

Returns the maximum value of *expr*. `MAX()` may take a string argument; in such cases, it returns the maximum string value. See [Section 8.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword

can be used to find the maximum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MAX()` returns `NULL`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
FROM student
GROUP BY student_name;
```

For `MAX()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- `MIN([DISTINCT] expr)`

Returns the minimum value of *expr*. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See [Section 8.3.1, "How MySQL Uses Indexes"](#). The `DISTINCT` keyword can be used to find the minimum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MIN()` returns `NULL`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
FROM student
GROUP BY student_name;
```

For `MIN()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- `STD(expr)`

Returns the population standard deviation of *expr*. `STD()` is a synonym for the standard SQL function `STDDEV_POP()`, provided as a MySQL extension.

If there are no matching rows, `STD()` returns `NULL`.

- `STDDEV(expr)`

Returns the population standard deviation of *expr*. `STDDEV()` is a synonym for the standard SQL function `STDDEV_POP()`, provided for compatibility with Oracle.

If there are no matching rows, `STDDEV()` returns `NULL`.

- `STDDEV_POP(expr)`

Returns the population standard deviation of *expr* (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

If there are no matching rows, `STDDEV_POP()` returns `NULL`.

- `STDDEV_SAMP(expr)`

Returns the sample standard deviation of *expr* (the square root of `VAR_SAMP()`).

If there are no matching rows, `STDDEV_SAMP()` returns `NULL`.

- `SUM([DISTINCT] expr)`

Returns the sum of *expr*. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of *expr*.

If there are no matching rows, `SUM()` returns `NULL`.

- `VAR_POP(expr)`

Returns the population standard variance of `expr`. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()`, which is equivalent but is not standard SQL.

If there are no matching rows, `VAR_POP()` returns `NULL`.

- `VAR_SAMP(expr)`

Returns the sample variance of `expr`. That is, the denominator is the number of rows minus one.

If there are no matching rows, `VAR_SAMP()` returns `NULL`.

- `VARIANCE(expr)`

Returns the population standard variance of `expr`. `VARIANCE()` is a synonym for the standard SQL function `VAR_POP()`, provided as a MySQL extension.

If there are no matching rows, `VARIANCE()` returns `NULL`.

12.17.2 GROUP BY Modifiers

The `GROUP BY` clause permits a `WITH ROLLUP` modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. `ROLLUP` thus enables you to answer questions at multiple levels of analysis with a single query. For example, `ROLLUP` can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a `sales` table has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```
CREATE TABLE sales
(
  year      INT,
  country   VARCHAR(20),
  product   VARCHAR(32),
  profit    INT
);
```

To summarize table contents per year, use a simple `GROUP BY` like this:

```
mysql> SELECT year, SUM(profit) AS profit
        FROM sales
        GROUP BY year;
+-----+-----+
| year | profit |
+-----+-----+
| 2000 |  4525 |
| 2001 |  3010 |
+-----+-----+
```

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use `ROLLUP`, which provides both levels of analysis with a single query. Adding a `WITH ROLLUP` modifier to the `GROUP BY` clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

```
mysql> SELECT year, SUM(profit) AS profit
        FROM sales
        GROUP BY year WITH ROLLUP;
+-----+-----+
| year | profit |
+-----+-----+
| 2000 |  4525 |
| 2001 |  3010 |
| NULL |  7535 |
+-----+-----+
```

The `NULL` value in the `year` column identifies the grand total super-aggregate line.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary of the `sales` table based on `year`, `country`, and `product` might look like this, where the output indicates summary values only at the year/country/product level of analysis:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product;
```

| year | country | product | profit |
|------|---------|------------|--------|
| 2000 | Finland | Computer | 1500 |
| 2000 | Finland | Phone | 100 |
| 2000 | India | Calculator | 150 |
| 2000 | India | Computer | 1200 |
| 2000 | USA | Calculator | 75 |
| 2000 | USA | Computer | 1500 |
| 2001 | Finland | Phone | 10 |
| 2001 | USA | Calculator | 50 |
| 2001 | USA | Computer | 2700 |
| 2001 | USA | TV | 250 |

With `ROLLUP` added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP;
```

| year | country | product | profit |
|------|---------|------------|--------|
| 2000 | Finland | Computer | 1500 |
| 2000 | Finland | Phone | 100 |
| 2000 | Finland | NULL | 1600 |
| 2000 | India | Calculator | 150 |
| 2000 | India | Computer | 1200 |
| 2000 | India | NULL | 1350 |
| 2000 | USA | Calculator | 75 |
| 2000 | USA | Computer | 1500 |
| 2000 | USA | NULL | 1575 |
| 2000 | NULL | NULL | 4525 |
| 2001 | Finland | Phone | 10 |
| 2001 | Finland | NULL | 10 |
| 2001 | USA | Calculator | 50 |
| 2001 | USA | Computer | 2700 |
| 2001 | USA | TV | 250 |
| 2001 | USA | NULL | 3000 |
| 2001 | NULL | NULL | 3010 |
| NULL | NULL | NULL | 7535 |

Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the `product` column set to `NULL`.
- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`.
- Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has changed value. For any column in the result set with a name that matches any of those names, its value is set to `NULL`. (If you specify grouping columns by column position, the server identifies which columns to set to `NULL` by position.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as `NULL` values only in the select list or `HAVING` clause. You cannot test them as `NULL` values in join conditions or the `WHERE` clause to determine which rows to select. For example, you cannot add `WHERE product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

The `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a `NULL` represents a regular grouped value or a super-aggregate value.

Other Considerations When using ROLLUP

The following discussion lists some behaviors specific to the MySQL implementation of `ROLLUP`.

When you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` are mutually exclusive in MySQL. However, you still have some control over sort order. `GROUP BY` in MySQL implicitly sorts results by default (in the absence of `ASC` or `DESC` designators). However, implicit `GROUP BY` sorting in MySQL is deprecated. To achieve a specific sort order of grouped results:

- Use explicit `ASC` and `DESC` keywords with columns named in the `GROUP BY` list to specify sort order for individual columns. In this case, the super-aggregate summary rows added by `ROLLUP` still appear after the rows from which they are calculated, regardless of the sort order.
- To work around the restriction that prevents using `ROLLUP` with `ORDER BY`, generate the grouped result set as a derived table and apply `ORDER BY` to it. For example:

```
mysql> SELECT * FROM
      (SELECT year, SUM(profit) AS profit
       FROM sales GROUP BY year WITH ROLLUP) AS dt
      ORDER BY year DESC;
```

| year | profit |
|------|--------|
| 2001 | 3010 |
| 2000 | 4525 |
| NULL | 7535 |

In this case, the super-aggregate summary rows sort with the rows from which they are calculated, and their placement depends on sort order (at the beginning for ascending sort, at the end for descending sort).

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
      FROM sales
      GROUP BY year, country, product WITH ROLLUP
      LIMIT 5;
```

| year | country | product | profit |
|------|---------|------------|--------|
| 2000 | Finland | Computer | 1500 |
| 2000 | Finland | Phone | 100 |
| 2000 | Finland | NULL | 1600 |
| 2000 | India | Calculator | 150 |
| 2000 | India | Computer | 1200 |

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because there is less context for understanding the super-aggregate rows.

A MySQL extension permits a column that does not appear in the `GROUP BY` list to be named in the select list. (For information about nonaggregated columns and `GROUP BY`, see [Section 12.17.3, “MySQL Handling of GROUP BY”](#).) In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are nondeterministic:

```
mysql> SELECT year, country, SUM(profit) AS profit
        FROM sales
        GROUP BY year WITH ROLLUP;
```

| year | country | profit |
|------|---------|--------|
| 2000 | India | 4525 |
| 2001 | USA | 3010 |
| NULL | USA | 7535 |

This behavior is permitted when the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause.

12.17.3 MySQL Handling of GROUP BY

In standard SQL, a query that includes a `GROUP BY` clause cannot refer to nonaggregated columns in the select list that are not named in the `GROUP BY` clause. For example, this query is illegal in standard SQL because the nonaggregated `name` column in the select list does not appear in the `GROUP BY`:

```
SELECT o.custid, c.name, MAX(o.payment)
   FROM orders AS o, customers AS c
  WHERE o.custid = c.custid
  GROUP BY o.custid;
```

For the query to be legal, the `name` column must be omitted from the select list or named in the `GROUP BY` clause.

MySQL extends the standard SQL use of `GROUP BY` so that the select list can refer to nonaggregated columns not named in the `GROUP BY` clause. This means that the preceding query is legal in MySQL. You can use this feature to get better performance by avoiding unnecessary column sorting and grouping. However, this is useful primarily when all values in each nonaggregated column not named in the `GROUP BY` are the same for each group. The server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic. Furthermore, the selection of values from each group cannot be influenced by adding an `ORDER BY` clause. Result set sorting occurs after values have been chosen, and `ORDER BY` does not affect which values within each group the server chooses.

A similar MySQL extension applies to the `HAVING` clause. In standard SQL, a query cannot refer to nonaggregated columns in the `HAVING` clause that are not named in the `GROUP BY` clause. To simplify calculations, a MySQL extension permits references to such columns. This extension assumes that the nongrouped columns have the same group-wise values. Otherwise, the result is nondeterministic.

To disable the MySQL `GROUP BY` extension and enable standard SQL behavior, enable the `ONLY_FULL_GROUP_BY` SQL mode. In this case, columns not named in the `GROUP BY` clause cannot be used in the select list or `HAVING` clause unless enclosed in an aggregate function.

The select list extension also applies to `ORDER BY`. That is, you can refer to nonaggregated columns in the `ORDER BY` clause that do not appear in the `GROUP BY` clause. (However, as mentioned previously, `ORDER BY` does not affect which values are chosen from nonaggregated columns; it only sorts them after they have been chosen.) This extension does not apply if the `ONLY_FULL_GROUP_BY` SQL mode is enabled.

If a query has aggregate functions and no `GROUP BY` clause, it cannot have nonaggregated columns in the select list, `HAVING` condition, or `ORDER BY` list with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT(),...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group.

Another MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. Enabling `ONLY_FULL_GROUP_BY` prevents this. For example, the following query returns `name` values that occur only once in table `orders`; the query is accepted regardless of whether `ONLY_FULL_GROUP_BY` is enabled:

```
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The following query is accepted only if `ONLY_FULL_GROUP_BY` is disabled.

```
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

If you are trying to follow standard SQL, you can use only column expressions in `GROUP BY` clauses. As a workaround, use an alias for the expression:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

MySQL permits noncolumn expressions in `GROUP BY` clauses, so the alias is unnecessary:

```
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

12.18 Miscellaneous Functions

Table 12.22 Miscellaneous Functions

| Name | Description |
|--------------------------------|---|
| <code>DEFAULT()</code> | Return the default value for a table column |
| <code>INET_ATON()</code> | Return the numeric value of an IP address |
| <code>INET_NTOA()</code> | Return the IP address from a numeric value |
| <code>MASTER_POS_WAIT()</code> | Block until the slave has read and applied all updates up to the specified position |
| <code>NAME_CONST()</code> | Cause the column to have the given name |
| <code>SLEEP()</code> | Sleep for a number of seconds |
| <code>UUID()</code> | Return a Universal Unique Identifier (UUID) |
| <code>UUID_SHORT()</code> | Return an integer-valued universal identifier |
| <code>VALUES()</code> | Define the values to be used during an INSERT |

- `DEFAULT(col_name)`

Returns the default value for a table column. An error results if the column has no default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- `FORMAT(X, D)`

Formats the number *X* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 12.7, “String Functions and Operators”](#).

- `INET_ATON(expr)`

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_ATON('10.0.5.9');
-> 167773449
```

For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$.

`INET_ATON()` may or may not return a non-`NULL` result for short-form IP addresses (such as '127.1' as a representation of '127.0.0.1'). Because of this, `INET_ATON()` should not be used for such addresses.

Note

To store values generated by `INET_ATON()`, use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See [Section 11.1.7, “Out-of-Range and Overflow Handling”](#).

- `INET_NTOA(expr)`

Given a numeric IPv4 network address in network byte order, returns the dotted-quad representation of the address as a string. `INET_NTOA()` returns `NULL` if it does not understand its argument.

The return value is a string in the connection character set.

```
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

- `MASTER_POS_WAIT(log_name, log_pos[, timeout])`

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns `NULL` if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the slave SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the slave is past the specified position, the function returns immediately.

If a *timeout* value is specified, `MASTER_POS_WAIT()` stops waiting when *timeout* seconds have elapsed. *timeout* must be greater than 0; a zero or negative *timeout* means no timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `NAME_CONST(name, value)`

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
```

```
+-----+
|      14 |
+-----+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in [Section 20.7, “Stored Program Binary Logging”](#). You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+-----+
| myname |
+-----+
|      14 |
+-----+
1 row in set (0.00 sec)
```

See [Section 13.2.9, “SELECT Statement”](#), for more information about column aliases.

- `SLEEP(duration)`

Sleeps (pauses) for the number of seconds given by the *duration* argument, then returns 0. If `SLEEP()` is interrupted, it returns 1. The duration may have a fractional part.

When sleep returns normally (without interruption), it returns 0:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|              0 |
+-----+
```

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|              1 |
+-----+
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error. This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `UUID()`

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique Identifier (UUID) URN Namespace” (<http://www.ietf.org/rfc/rfc4122.txt>).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

Warning

Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

`UUID()` returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a `utf8` string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD, Linux, and Windows. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-5b8c656024db'
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `UUID_SHORT()`

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by `UUID_SHORT()` differ from the string-format 128-bit identifiers returned by the `UUID()` function and have different uniqueness properties. The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The `server_id` value of the current server is between 0 and 255 and is unique among your set of master and slave servers
- You do not set back the system time for your server host between `mysqld` restarts
- You invoke `UUID_SHORT()` on average fewer than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
```

```
-> 92395783831158784
```

**Note**

`UUID_SHORT()` does not work with statement-based replication.

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See [Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”](#).

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

12.19 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that is merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see [Section 5.1.10, “Server SQL Modes”](#).

12.19.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and `DECIMAL` types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

12.19.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of `DECIMAL` columns

Possible incompatibilities with applications that are written for older versions of MySQL (prior to 5.0.3) are noted throughout this section.

The declaration syntax for a `DECIMAL` column is `DECIMAL(M,D)`. The ranges of values for the arguments are as follows:

- `M` is the maximum number of digits (the precision). It has a range of 1 to 65. (Older versions of MySQL permitted a range of 1 to 254.)
- `D` is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than `M`.

If `D` is omitted, the default is 0. If `M` is omitted, the default is 10.

The maximum value of 65 for `M` means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before. (In older versions of MySQL, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.)

Values for `DECIMAL` columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

| Leftover Digits | Number of Bytes |
|-----------------|-----------------|
| 0 | 0 |
| 1–2 | 1 |
| 3–4 | 2 |
| 5–6 | 3 |
| 7–9 | 4 |

For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen

integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

Unlike some older versions of MySQL, `DECIMAL` columns in MySQL 5.5 do not store a leading `+` character or `-` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored. Applications that rely on the older behavior must be modified to account for this change.

`DECIMAL` columns do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column permits up to $M - D$ digits to the left of the decimal point. This is not compatible with applications relying on older versions of MySQL that permitted storing an extra digit in lieu of a `+` sign.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly* M digits. For `DECIMAL(M,D)`, the standard requires a precision of at least M digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly M digits.

For a full explanation of the internal format of `DECIMAL` values, see the file `strings/decimal.c` in a MySQL source distribution. The format is explained (with an example) in the `decimal2bin()` function.

For more detailed information about porting applications that rely on the old treatment of the `DECIMAL` data type, see the *MySQL 5.0 Reference Manual*.

12.19.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 5.1.10, “Server SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in [Section 12.19.4, “Rounding Behavior”](#). Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of `NULL` and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

| sql_mode Value | Result |
|---|--|
| ' ' (Default) | No warning, no error; <code>i</code> is set to <code>NULL</code> . |
| strict | No warning, no error; <code>i</code> is set to <code>NULL</code> . |
| <code>ERROR_FOR_DIVISION_BY_ZERO</code> | Warning, no error; <code>i</code> is set to <code>NULL</code> . |
| strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code> | Error condition; no row is inserted. |

12.19.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other

words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3         | 2           |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1265 | Data truncated for column 'd' at row 1 |
| Note  | 1265 | Data truncated for column 'd' at row 2 |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT d FROM t;
+-----+
| d     |
+-----+
| 3     |
| 3     |
+-----+
2 rows in set (0.00 sec)
```

The `SHOW WARNINGS` statement displays the notes that are generated by truncation due to rounding of the fractional part. Such truncation is not an error, even in strict SQL mode (see [Section 12.19.3, “Expression Handling”](#)).

12.19.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in [Section 12.19.3, “Expression Handling”](#), and [Section 12.19.4, “Rounding Behavior”](#).

Example 1. Numbers are used with their exact value as given when possible:

```
mysql> SELECT (.1 + .2) = .3;
+-----+
| (.1 + .2) = .3 |
+-----+
| 1              |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT (.1E0 + .2E0) = .3E0;
```

```

+-----+
| (.1E0 + .2E0) = .3E0 |
+-----+
|                          0 |
+-----+

```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;

```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```

+-----+
| d      | f |
+-----+
| 1.0000 | 0.999999999999991 |
+-----+

```

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers `X1` and `X2` that have scale `S1` and `S2`, the scale of the result is `S1 + S2`:

```

mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+

```

Example 3. Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half away from zero” rule. A value with a fractional part of `.5` or greater is rounded away from zero to the nearest integer, as shown here:

```

mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+
| 3          | -3          |
+-----+

```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. A value with a fractional part exactly half way between two integers is rounded to the nearest even integer:

```

mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+
| 2            | -2            |
+-----+

```

Example 4. In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127  |
+-----+
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| NULL  |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
```

```
Empty set (0.01 sec)
```

Example 6. Exact-value literals are evaluated as exact values.

Prior to MySQL 5.0.3, exact-value and approximate-value literals both are evaluated as double-precision floating-point values:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 4.1.18-log |
+-----+
1 row in set (0.01 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.07 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | double(3,1)  |      |     | 0.0     |       |
| b     | double       |      |     | 0       |       |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.04 sec)
```

As of MySQL 5.0.3, the approximate-value literal is evaluated using floating point, but the exact-value literal is handled as **DECIMAL**:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 5.1.6-alpha-log |
+-----+
1 row in set (0.11 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | decimal(2,1) unsigned | NO  |     | 0.0     |       |
| b     | double       | NO  |     | 0       |       |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

Before MySQL 5.0.3, the result is a double no matter the argument type:

```
mysql> DESCRIBE y;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| AVG(i) | double(17,4) | YES  |     | NULL    |       |
| AVG(d) | double(17,4) | YES  |     | NULL    |       |
| AVG(f) | double       | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

As of MySQL 5.0.3, the result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
```

| Field | Type | Null | Key | Default | Extra |
|--------|---------------|------|-----|---------|-------|
| AVG(i) | decimal(14,4) | YES | | NULL | |
| AVG(d) | decimal(14,4) | YES | | NULL | |
| AVG(f) | double | YES | | NULL | |

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

Chapter 13 SQL Statements

Table of Contents

| | |

| 13.8.4 USE Statement | 1595 |

This chapter describes the syntax for the [SQL](#) statements supported by MySQL.

13.1 Data Definition Statements

13.1.1 ALTER DATABASE Statement

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
```

[ALTER DATABASE](#) enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use [ALTER DATABASE](#), you need the [ALTER](#) privilege on the database. [ALTER SCHEMA](#) is a synonym for [ALTER DATABASE](#).

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

National Language Characteristics

The [CHARACTER SET](#) clause changes the default database character set. The [COLLATE](#) clause changes the default database collation. [Chapter 10, Character Sets, Collations, Unicode](#), discusses character set and collation names.

You can see what character sets and collations are available using, respectively, the [SHOW CHARACTER SET](#) and [SHOW COLLATION](#) statements. See [Section 13.7.5.4, “SHOW CHARACTER SET Statement”](#), and [Section 13.7.5.5, “SHOW COLLATION Statement”](#), for more information.

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).)

Upgrading from Versions Older than MySQL 5.1

The syntax that includes the [UPGRADE DATA DIRECTORY NAME](#) clause updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see [Section 9.2.4, “Mapping of Identifiers to File Names”](#)). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by `mysqlcheck` (as invoked by `mysql_upgrade`).

For example, if a database in MySQL 5.0 has the name `a-b-c`, the name contains instances of the `-` (dash) character. In MySQL 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and later, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql150#a-b-c`, and you must refer to the name using the `#mysql150#` prefix. Use [UPGRADE DATA DIRECTORY NAME](#) in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql150#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql150#` prefix.

13.1.2 ALTER EVENT Statement

```
ALTER
  [DEFINER = user]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION [NOT] PRESERVE]
  [RENAME TO new_event_name]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'string']
  [DO event_body]
```

The [ALTER EVENT](#) statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the [DEFINER](#), [ON SCHEDULE](#), [ON COMPLETION](#), [COMMENT](#), [ENABLE / DISABLE](#), and [DO](#) clauses is exactly the same as when used with [CREATE EVENT](#). (See [Section 13.1.11, “CREATE EVENT Statement”](#).)

Any user can alter an event defined on a database for which that user has the [EVENT](#) privilege. When a user executes a successful [ALTER EVENT](#) statement, that user becomes the definer for the affected event.

[ALTER EVENT](#) works only with an existing event:

```
mysql> ALTER EVENT no_such_event
> ON SCHEDULE
> EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
ON SCHEDULE
EVERY 6 HOUR
COMMENT 'A sample comment.'
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
ON SCHEDULE
EVERY 12 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER EVENT myevent
ON SCHEDULE
AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO
TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the [EVENT](#) privilege on both the `olddb` and `newdb` databases.

Note

There is no [RENAME EVENT](#) statement.

The value [DISABLE ON SLAVE](#) is used on a replication slave instead of [ENABLE](#) or [DISABLE](#) to indicate an event that was created on the master and replicated to the slave, but that is not executed on the slave. Normally, [DISABLE ON SLAVE](#) is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See [Section 17.4.1.15, “Replication of Invoked Features”](#), for more information.

13.1.3 ALTER FUNCTION Statement

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an [ALTER FUNCTION](#) statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using [DROP FUNCTION](#) and [CREATE FUNCTION](#).

You must have the [ALTER ROUTINE](#) privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the [ALTER FUNCTION](#) statement might also require the [SUPER](#) privilege, as described in [Section 20.7, “Stored Program Binary Logging”](#).

13.1.4 ALTER LOGFILE GROUP Statement

```
ALTER LOGFILE GROUP logfile_group
  ADD UNDOFILE 'file_name'
  [INITIAL_SIZE [=] size]
  [WAIT]
  ENGINE [=] engine_name
```

This statement adds an [UNDO](#) file named '*file_name*' to an existing log file group *logfile_group*. An [ALTER LOGFILE GROUP](#) statement has one and only one [ADD UNDOFILE](#) clause. No [DROP UNDOFILE](#) clause is currently supported.

Note

All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional [INITIAL_SIZE](#) parameter sets the [UNDO](#) file's initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). Prior to MySQL NDB Cluster 7.2.14, this value was required to be specified using digits (Bug #13116514, Bug #16104705, Bug #62858); in MySQL NDB Cluster 7.2.14 and later, you may optionally follow *size* with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes).

On 32-bit systems, the maximum supported value for [INITIAL_SIZE](#) is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for [INITIAL_SIZE](#) is 1048576 (1 MB). (Bug #29574)

**Note**

`WAIT` is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The `ENGINE` parameter (required) determines the storage engine which is used by this log file group, with `engine_name` being the name of the storage engine. Currently, the only accepted values for `engine_name` are “`NDBCLUSTER`” and “`NDB`”. The two values are equivalent.

Here is an example, which assumes that the log file group `lg_3` has already been created using `CREATE LOGFILE GROUP` (see [Section 13.1.14, “CREATE LOGFILE GROUP Statement”](#)):

```
ALTER LOGFILE GROUP lg_3
  ADD UNDOFILE 'undo_10.dat'
  INITIAL_SIZE=32M
  ENGINE=NDBCLUSTER;
```

When `ALTER LOGFILE GROUP` is used with `ENGINE = NDBCLUSTER` (alternatively, `ENGINE = NDB`), an `UNDO` log file is created on each NDB Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
  -> FROM INFORMATION_SCHEMA.FILES
  -> WHERE LOGFILE_GROUP_NAME = 'lg_3';
```

| FILE_NAME | LOGFILE_GROUP_NUMBER | EXTRA |
|-------------|----------------------|----------------|
| newdata.dat | 0 | CLUSTER_NODE=3 |
| newdata.dat | 0 | CLUSTER_NODE=4 |
| undo_10.dat | 11 | CLUSTER_NODE=3 |
| undo_10.dat | 11 | CLUSTER_NODE=4 |

4 rows in set (0.01 sec)

(See [Section 21.30.1, “The INFORMATION_SCHEMA FILES Table”](#).)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

`ALTER LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. For more information, see [Section 18.5.12, “NDB Cluster Disk Data Tables”](#).

13.1.5 ALTER PROCEDURE Statement

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 20.2.2, “Stored Routines and MySQL Privileges”](#).

13.1.6 ALTER SERVER Statement

```
ALTER SERVER server_name
  OPTIONS (option [, option] ...)
```

Alters the server information for *server_name*, adjusting any of the options permitted in the [CREATE SERVER](#) statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the [SUPER](#) privilege.

For example, to update the `USER` option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.

13.1.7 ALTER TABLE Statement

```
ALTER [ONLINE|OFFLINE] [IGNORE] TABLE tbl_name
  [alter_specification [, alter_specification] ...]
  [partition_options]

alter_specification:
  table_options
  | ADD [COLUMN] col_name column_definition
    [FIRST | AFTER col_name]
  | ADD [COLUMN] (col_name column_definition,...)
  | ADD {INDEX|KEY} [index_name]
    [index_type] (key_part,...) [index_option] ...
  | ADD {FULLTEXT|SPATIAL} [INDEX|KEY] [index_name]
    (key_part,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] PRIMARY KEY
    [index_type] (key_part,...)
    [index_option] ...
  | ADD [CONSTRAINT [symbol]] UNIQUE [INDEX|KEY]
    [index_name] [index_type] (key_part,...)
    [index_option] ...
  | ADD [CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (col_name,...)
    reference_definition
  | ADD CHECK (expr)
  | ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
  | CHANGE [COLUMN] old_col_name new_col_name column_definition
    [FIRST|AFTER col_name]
  | [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
  | CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
  | {DISABLE|ENABLE} KEYS
  | {DISCARD|IMPORT} TABLESPACE
  | DROP [COLUMN] col_name
  | DROP {INDEX|KEY} index_name
  | DROP PRIMARY KEY
  | DROP FOREIGN KEY fk_symbol
  | FORCE
  | MODIFY [COLUMN] col_name column_definition
    [FIRST | AFTER col_name]
  | ORDER BY col_name [, col_name] ...
  | RENAME [TO|AS] new_tbl_name

partition_options:
  partition_option [partition_option] ...

partition_option:
  ADD PARTITION (partition_definition)
  | DROP PARTITION partition_names
  | TRUNCATE PARTITION {partition_names | ALL}
  | COALESCE PARTITION number
  | REORGANIZE PARTITION [partition_names INTO (partition_definitions)]
  | ANALYZE PARTITION {partition_names | ALL}
  | CHECK PARTITION {partition_names | ALL}
  | OPTIMIZE PARTITION {partition_names | ALL}
```

```

| REBUILD PARTITION {partition_names | ALL}
| REPAIR PARTITION {partition_names | ALL}
| PARTITION BY partitioning_expression
| REMOVE PARTITIONING

key_part:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH}

index_option:
  KEY_BLOCK_SIZE [=] value
| index_type
| WITH PARSER parser_name
| COMMENT 'string'

table_options:
  table_option [[,] table_option] ...

table_option:
  AUTO_INCREMENT [=] value
| AVG_ROW_LENGTH [=] value
| [DEFAULT] CHARACTER SET [=] charset_name
| CHECKSUM [=] {0 | 1}
| [DEFAULT] COLLATE [=] collation_name
| COMMENT [=] 'string'
| CONNECTION [=] 'connect_string'
| {DATA|INDEX} DIRECTORY [=] 'absolute path to directory'
| DELAY_KEY_WRITE [=] {0 | 1}
| ENGINE [=] engine_name
| INSERT_METHOD [=] { NO | FIRST | LAST }
| KEY_BLOCK_SIZE [=] value
| MAX_ROWS [=] value
| MIN_ROWS [=] value
| PACK_KEYS [=] {0 | 1 | DEFAULT}
| PASSWORD [=] 'string'
| ROW_FORMAT [=] {DEFAULT|DYNAMIC|FIXED|COMPRESSED|REDUNDANT|COMPACT}
| TABLESPACE tablespace_name [STORAGE {DISK|MEMORY}]
| UNION [=] (tbl_name[, tbl_name]...)

```

ALTER TABLE changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use **ALTER TABLE**, you need **ALTER**, **CREATE**, and **INSERT** privileges for the table. Renaming a table requires **ALTER** and **DROP** on the old table, **ALTER**, **CREATE**, and **INSERT** on the new table.
- Following the table name, specify the alterations to be made. If none are given, **ALTER TABLE** does nothing.
- The syntax for many of the permissible alterations is similar to clauses of the **CREATE TABLE** statement. *column_definition* clauses use the same syntax for **ADD** and **CHANGE** as for **CREATE TABLE**. For more information, see [Section 13.1.17, “CREATE TABLE Statement”](#).
- The word **COLUMN** is optional and can be omitted.
- Multiple **ADD**, **ALTER**, **DROP**, and **CHANGE** clauses are permitted in a single **ALTER TABLE** statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per **ALTER TABLE** statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- If a storage engine does not support an attempted **ALTER TABLE** operation, a warning may result. Such warnings can be displayed with **SHOW WARNINGS**. See [Section 13.7.5.41, “SHOW WARNINGS Statement”](#). For information on troubleshooting **ALTER TABLE**, see [Section B.4.6.1, “Problems with ALTER TABLE”](#).

- For usage examples, see [Section 13.1.7.2, “ALTER TABLE Examples”](#).
- With the `mysql_info()` C API function, you can find out how many rows were copied by `ALTER TABLE`, and (when `IGNORE` is used) how many rows were deleted due to duplication of unique key values. See [Section 23.7.6.35, “mysql_info\(\)”](#).

There are several additional aspects to the `ALTER TABLE` statement, described under the following topics in this section:

- [Table Options](#)
- [Performance and Space Requirements](#)
- [Adding and Dropping Columns](#)
- [Renaming, Redefining, and Reordering Columns](#)
- [Primary Keys and Indexes](#)
- [Foreign Keys and Other Constraints](#)
- [Changing the Character Set](#)
- [Discarding and Importing InnoDB Tablespaces](#)
- [Row Order for MyISAM Tables](#)
- [Partitioning Options](#)

Table Options

table_options signifies table options of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, `AVG_ROW_LENGTH`, `MAX_ROWS`, or `ROW_FORMAT`.

For descriptions of all table options, see [Section 13.1.17, “CREATE TABLE Statement”](#). However, `ALTER TABLE` ignores `DATA DIRECTORY` and `INDEX DIRECTORY` when given as table options. `ALTER TABLE` permits them only as partitioning options, and, as of MySQL 5.5.54, requires that you have the `FILE` privilege.

Use of table options with `ALTER TABLE` provides a convenient way of altering single table characteristics. For example:

- If `t1` is currently not an `InnoDB` table, this statement changes its storage engine to `InnoDB`:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

- See [Section 14.9.1.3, “Converting Tables from MyISAM to InnoDB”](#) for considerations when switching tables to the `InnoDB` storage engine.
- When you specify an `ENGINE` clause, `ALTER TABLE` rebuilds the table. This is true even if the table already has the specified storage engine.
- You can also use `ALTER TABLE tbl_name FORCE` to perform a “null” alter operation that rebuilds the table.
- The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.10, “Server SQL Modes”](#).
- To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.
- To change the `InnoDB` table to use compressed row-storage format:

```
ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
```

- To reset the current auto-increment value:

```
ALTER TABLE t1 AUTO_INCREMENT = 13;
```

You cannot reset the counter to a value less than or equal to any that have already been used. For [MyISAM](#), if the value is less than or equal to the maximum value currently in the [AUTO_INCREMENT](#) column, the value is reset to the current maximum plus one. For [InnoDB](#), if the value is less than the current maximum value in the column, no error occurs and the current sequence value is not changed.

- To change the default table character set:

```
ALTER TABLE t1 CHARACTER SET = utf8;
```

See also [Changing the Character Set](#).

- To add (or change) a table comment:

```
ALTER TABLE t1 COMMENT = 'New table comment';
```

To verify that the table options were changed as intended, use [SHOW CREATE TABLE](#), or query the [INFORMATION_SCHEMA.TABLES](#) table.

Performance and Space Requirements

[ALTER TABLE](#) operations are processed using either the *table-copy* method or *in-place* method. Operations that use the table-copy method are performed on a temporary copy of the original table, which can require more time, particularly for large tables. Operations that use the in place method do not create temporary copy of the table and tend to be faster.

[ALTER TABLE](#) operations that are performed on a temporary copy of the original table wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the [ALTER TABLE](#) operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the [ALTER TABLE](#) operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a [RENAME TO](#) operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that [ALTER TABLE](#) blocks reads (not just writes) at the point where it is ready to install a new version of the table `.frm` file, discard the old file, and clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

To force use of the table-copy method for an [ALTER TABLE](#) operation that would otherwise not use it, enable the `old_alter_table` system variable.

For [InnoDB](#) tables, a table-copying [ALTER TABLE](#) operation on table that resides in a shared tablespace such as the [system tablespace](#) can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a [file-per-table](#) tablespace.

[ALTER TABLE](#) operations that use the in-place method include:

- [ALTER TABLE tbl_name RENAME TO new_tbl_name](#) operations executed without any other options. MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the [RENAME TABLE](#) statement to rename tables. See [Section 13.1.32, "RENAME TABLE Statement"](#).) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
- Operations that only modify table metadata. These operations are immediate because the server only alters the table `.frm` file, not touch table contents. Metadata-only operations include:

- Renaming a column (except for [InnoDB](#) tables).
- Changing the default value of a column (except for [NDB](#) tables; see [Limitations of NDB online operations](#)).
- Changing the definition of an [ENUM](#) or [SET](#) column by adding new enumeration or set members to the *end* of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a [SET](#) column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
- Adding or dropping a secondary index, for [InnoDB](#) and [NDBCLUSTER](#) tables. See [Section 14.16, “InnoDB Fast Index Creation”](#).
- For [NDBCLUSTER](#) tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See [Section 18.5.13, “Online Operations with ALTER TABLE in NDB Cluster”](#).

For [MyISAM](#) tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

`ALTER TABLE` with `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REBUILD PARTITION`, or `REORGANIZE PARTITION` does not create temporary tables (except when used with [NDB](#) tables); however, these operations can and do create temporary partition files.

`ADD` or `DROP` operations for [RANGE](#) or [LIST](#) partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for [HASH](#) or [KEY](#) partitions copy data between all partitions, unless [LINEAR HASH](#) or [LINEAR KEY](#) was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

Note

Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.

Adding and Dropping Columns

Use `ADD` to add new columns to a table, and `DROP` to remove existing columns. `DROP col_name` is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the `DROP TABLE` statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well.

Renaming, Redefining, and Reordering Columns

The `CHANGE`, `MODIFY`, and `ALTER` clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- `CHANGE`:
 - Can rename a column and change its definition, or both.
 - Has more capability than `MODIFY`, but at the expense of convenience for some operations. `CHANGE` requires naming the column twice if not renaming it.

- With `FIRST` or `AFTER`, can reorder columns.
- `MODIFY`:
 - Can change a column definition but not its name.
 - More convenient than `CHANGE` to change a column definition without renaming it.
 - With `FIRST` or `AFTER`, can reorder columns.
- `ALTER`: Used only to change a column default value.

`CHANGE` is a MySQL extension to standard SQL. `MODIFY` is a MySQL extension for Oracle compatibility.

To alter a column to change both its name and definition, use `CHANGE`, specifying the old and new names and the new definition. For example, to rename an `INT NOT NULL` column from `a` to `b` and change its definition to use the `BIGINT` data type while retaining the `NOT NULL` attribute, do this:

```
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```

To change a column definition but not its name, use `CHANGE` or `MODIFY`. With `CHANGE`, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column `b`, do this:

```
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

`MODIFY` is more convenient to change the definition without changing the name because it requires the column name only once:

```
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use `CHANGE`. The syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an `INT NOT NULL` column from `b` to `a`, do this:

```
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

For column definition changes using `CHANGE` or `MODIFY`, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as `PRIMARY KEY` or `UNIQUE`. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows, intending to change only `INT` to `BIGINT`:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

That statement changes the data type from `INT` to `BIGINT`, but it also drops the `UNSIGNED`, `DEFAULT`, and `COMMENT` attributes. To retain them, the statement must include them explicitly:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.

Warning

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see [Section 5.1.10](#), “Server SQL Modes”).

If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by `CHANGE`, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including indexes and disabled `MyISAM` indexes.

For columns renamed by `CHANGE`, MySQL does not automatically rename these references to the renamed column:

- Foreign keys that refer to the old column.
- Partition expressions that refer to the renamed column. You must use `CHANGE` to redefine such expressions in the same `ALTER TABLE` statement as the one that renames the column.
- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.

`ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in [Section 11.5, “Data Type Default Values”](#).

Primary Keys and Indexes

`DROP PRIMARY KEY` drops the [primary key](#). If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for `InnoDB` tables, see [Section 8.3.2, “Primary Key Optimization”](#).

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`IGNORE` is a MySQL extension to standard SQL. It controls how `ALTER TABLE` works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If `IGNORE` is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If `IGNORE` is specified, only one row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.

Note

Due to a bug related to [Fast Index Creation](#) (Bug #40344), `ALTER IGNORE TABLE ... ADD UNIQUE INDEX` does not delete duplicate rows. The `IGNORE` keyword is ignored. If any duplicate rows exist, the operation fails with a `Duplicate entry` error. A workaround is to set `old_alter_table=1` prior to running an `ALTER IGNORE TABLE ... ADD UNIQUE INDEX` statement.

```
SET SESSION old_alter_table=1
```

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See [Section 13.1.24, “DROP INDEX Statement”](#). To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see [Section 13.1.13, “CREATE INDEX Statement”](#). The preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

`index_option` values specify additional options for an index. For details about permissible `index_option` values, see [Section 13.1.13, “CREATE INDEX Statement”](#).

If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For `MyISAM` tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. `MyISAM` does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See [Section 13.7.5.23, “SHOW INDEX Statement”](#).

Foreign Keys and Other Constraints

If `ALTER TABLE` for an `InnoDB` table results in changes to column values (for example, because a column is truncated), `InnoDB`'s `FOREIGN KEY` constraint checks do not notice possible violations caused by changing the values.

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` storage engine, which implements `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See [Section 13.1.17.6, “FOREIGN KEY Constraints”](#). For other storage engines, the clauses are parsed but ignored.

The `CHECK` constraint clause is parsed but ignored by all storage engines. See [Section 13.1.17, “CREATE TABLE Statement”](#). The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See [Section 1.7.2, “MySQL Differences from Standard SQL”](#).

For `ALTER TABLE`, unlike `CREATE TABLE, ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (...)
```

Important

MySQL silently ignores inline `REFERENCES` specifications, where the references are defined as part of the column specification. MySQL accepts only `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

Note

Partitioned `InnoDB` tables do not support foreign keys. For more information, see [Section 19.5.2, “Partitioning Limitations Relating to Storage Engines”](#).

`InnoDB` supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in separate clauses of a single `ALTER TABLE` statement may be problematic in some cases and is therefore unsupported. Use separate statements for each operation.

`ALTER TABLE tbl_name RENAME new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string “`tbl_name_ibfk_`” to reflect the new table name. `InnoDB` interprets foreign key constraint names that begin with the string “`tbl_name_ibfk_`” as internally generated names.

Changing the Character Set

To change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name];
```

The statement also changes the collation of all character columns. If you specify no `COLLATE` clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of `VARCHAR` or one of the `TEXT` types, `CONVERT TO CHARACTER SET` changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a `TEXT` column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a `latin1 TEXT` column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to `utf8`, each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length does not fit in a `TEXT` column's length bytes, so MySQL converts the data type to `MEDIUMTEXT`, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a `VARCHAR` column might be converted to `MEDIUMTEXT`.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer will have a character set and a subsequent `CONVERT TO` operation will not apply to them.

If *charset_name* is `DEFAULT` in a `CONVERT TO CHARACTER SET` operation, the character set named by the `character_set_database` system variable is used.

Warning

The `CONVERT TO` operation converts column values between the original and named character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When the `foreign_key_checks` system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

Discarding and Importing InnoDB Tablespaces

For an InnoDB table that is created with its own tablespace in an `.ibd` file, that file can be discarded and imported. To discard the `.ibd` file, use this statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

This deletes the current `.ibd` file, so be sure that you have a backup first. Attempting to access the table while the tablespace file is discarded results in an error.

To import the backup `.ibd` file back into the table, copy it into the database directory, and then issue this statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

The tablespace file must have been created on the server into which it is imported later.

Note

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data.

See [Section 14.9.3.2, “File-Per-Table Tablespaces”](#).

Row Order for MyISAM Tables

`ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

Note

The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for InnoDB tables because InnoDB always orders table rows according to the [clustered index](#).

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

Partitioning Options

`partition_options` signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions.

For a list of partition options and a description of each, see [Section 13.1.17, “CREATE TABLE Statement”](#). For additional information, see [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#).

13.1.7.1 ALTER TABLE Partition Operations

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, to add, drop, discard, merge, and split partitions, and to perform partitioning maintenance.

- Simply using a `partition_options` clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the `partition_options`. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the `partition_options` clause for `CREATE TABLE` (for more detailed information, see [Section 13.1.17, “CREATE TABLE Statement”](#)), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
);
```

This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
  PARTITION BY HASH(id)
  PARTITIONS 8;
```

MySQL 5.5.31 and later supports an `ALGORITHM` option with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

To upgrade a `KEY` partitioned table that was created in MySQL 5.1, first execute `SHOW CREATE TABLE` and note the exact columns and number of partitions shown. Now execute an `ALTER TABLE` statement using exactly the same column list and number of partitions as in the `CREATE TABLE` statement, while adding `ALGORITHM=2` immediately following the `PARTITION BY` keywords. (You should also include the `LINEAR` keyword if it was used for the original table definition.) An example from a session in the `mysql` client is shown here:

```
mysql> SHOW CREATE TABLE p\G
***** 1. row *****
      Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)

mysql> ALTER TABLE p PARTITION BY LINEAR KEY ALGORITHM=2 (id) PARTITIONS 32;
Query OK, 0 rows affected (5.34 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE p\G
***** 1. row *****
      Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
```

```
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)
```

Downgrading a table created using the default key-hashing used in MySQL 5.5 and later to enable its use by a MySQL 5.1 server is similar, except in this case you should use `ALGORITHM=1` to force the table's partitions to be rebuilt using the MySQL 5.1 key-hashing functions. It is recommended that you not do this except when necessary for compatibility with a MySQL 5.1 server, as the improved `KEY` hashing functions used by default in MySQL 5.5 and later provide fixes for a number of issues found in the older implementation.

Note

A table upgraded by means of `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY ...` can no longer be used by a MySQL 5.1 server. (Such a table would need to be downgraded with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY ...` before it could be used again by a MySQL 5.1 server.)

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Section 19.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See [Section 13.1.17, “CREATE TABLE Statement”](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the `partition_names` list is discarded.

For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note

`DROP PARTITION` does not work with tables that use the `NDBCLUSTER` storage engine. See [Section 19.3.1, “Management of RANGE and LIST Partitions”](#), and [Section 18.1.7, “Known Limitations of NDB Cluster”](#).

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

Renames of partitioned tables are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation copies the partition's data.

To delete rows from selected partitions, use the `TRUNCATE PARTITION` option. This option takes a list of one or more comma-separated partition names. For example, consider the table `t1` as defined here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2003),
  PARTITION p4 VALUES LESS THAN (2007)
);
```

To delete all rows from partition `p0`, use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex `WHERE` conditions if done with `DELETE` statements. For example, this statement deletes all rows from partitions `p1` and `p3`:

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent `DELETE` statement is shown here:

```
DELETE FROM t1 WHERE
  (year_col >= 1991 AND year_col < 1995)
OR
```

```
(year_col >= 2003 AND year_col < 2007);
```

If you use the [ALL](#) keyword in place of the list of partition names, the statement acts on all table partitions.

[TRUNCATE PARTITION](#) merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

Note

[TRUNCATE PARTITION](#) does not work with subpartitions.

To verify that the rows were dropped, check the [INFORMATION_SCHEMA.PARTITIONS](#) table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 't1';
```

[TRUNCATE PARTITION](#) is supported only for partitioned tables that use the [MyISAM](#), [InnoDB](#), or [MEMORY](#) storage engine. It also works on [BLACKHOLE](#) tables (but has no effect). It is not supported for [ARCHIVE](#) tables.

[COALESCE PARTITION](#) can be used with a table that is partitioned by [HASH](#) or [KEY](#) to reduce the number of partitions by *number*. Suppose that you have created table *t2* as follows:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

To reduce the number of partitions used by *t2* from 6 to 4, use the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use [REORGANIZE PARTITION](#). This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the *partition_names* list and supplying a single definition for *partition_definition*.
- To split an existing partition into several partitions. Accomplish this by naming a single partition for *partition_names* and providing multiple *partition_definitions*.
- To change the ranges for a subset of partitions defined using [VALUES LESS THAN](#) or the value lists for a subset of partitions defined using [VALUES IN](#).
- This statement may also be used without the *partition_names INTO (partition_definitions)* option on tables that are automatically partitioned using [HASH](#) partitioning to force redistribution of data. (Currently, only [NDB](#) tables are automatically partitioned in this way.) This is useful in [NDB Cluster](#) where, after you have added new [NDB Cluster](#) data nodes online to an existing [NDB Cluster](#), you wish to redistribute existing [NDB Cluster](#) table data

to the new data nodes. In such cases, you should invoke the statement with the `ONLINE` option; in other words, as shown here:

```
ALTER ONLINE TABLE table REORGANIZE PARTITION;
```

You cannot perform other DDL concurrently with online table reorganization—that is, no other DDL statements can be issued while an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement is executing. For more information about adding NDB Cluster data nodes online, see [Section 18.5.14, “Adding NDB Cluster Data Nodes Online”](#).

`ALTER ONLINE TABLE ... REORGANIZE PARTITION` does not work with tables which were created using the `MAX_ROWS` option, because it uses the constant `MAX_ROWS` value specified in the original `CREATE TABLE` statement to determine the number of partitions required, so no new partitions are created. Beginning with MySQL NDB Cluster 7.2.6, you can use `ALTER ONLINE TABLE ... MAX_ROWS=rows` to increase the maximum number of rows for such a table; in this case, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` is not needed (and causes an error if executed). The value of `rows` must be greater than the value specified for `MAX_ROWS` in the original `CREATE TABLE` statement for this to work.

Attempting to use `REORGANIZE PARTITION` without the `partition_names INTO (partition_definitions)` option on explicitly partitioned tables results in the error `REORGANIZE PARTITION without parameters can only be used on auto-partitioned tables using HASH partitioning`.

Note

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see [Section 19.3.1, “Management of RANGE and LIST Partitions”](#).

- Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; for more information, see [Section 13.7.2, “Table Maintenance Statements”](#)). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a `partition_names` clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. You can also use the `ALL` keyword in place of `partition_names`, in which case the statement acts on all table partitions. For more information and examples, see [Section 19.3.3, “Maintenance of Partitions”](#).

Prior to MySQL 5.5.30, it was not safe to execute multiple concurrent `REBUILD TABLE` operations on partitioned tables, whether on the same or different tables. (Bug #14589559, Bug #66645)

Some MySQL storage engines, such as `InnoDB`, do not support per-partition optimization. For a partitioned table using such a storage engine, `ALTER TABLE ... OPTIMIZE PARTITION` rebuilds the entire table. This is a known issue. Beginning with MySQL 5.5.30, running this statement on such a table causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822)

To work around this problem, use the statements `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not permitted for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.
- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see [Section 13.1.7.1, "ALTER TABLE Partition Operations"](#).

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

`ANALYZE`, `CHECK`, `OPTIMIZE`, `REBUILD`, `REPAIR`, and `TRUNCATE` operations are not supported for subpartitions.

13.1.7.2 ALTER TABLE Examples

Begin with a table `t1` created as shown here:

```
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,
  ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

For `NDB` tables, it is also possible to change the storage type used for a table or column. For example, consider an `NDB` table created as shown here:

```
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)
```

To convert this table to disk-based storage, you can use the following `ALTER TABLE` statement:

```
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
      Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the `ALTER TABLE`:

```
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.00 sec)

mysql> ALTER TABLE t2 STORAGE DISK;
ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (3.42 sec)
Records: 0 Duplicates: 0 Warnings: 0
mysql> SHOW CREATE TABLE t2\G
***** 1. row *****
      Table: t1
Create Table: CREATE TABLE `t2` (
  `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create an `NDB Cluster Disk Data` table with two columns, using this `CREATE TABLE` statement:

```
mysql> CREATE TABLE t3 (c1 INT, c2 INT)
->   TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE t3\G
***** 1. row *****
      Table: t3
Create Table: CREATE TABLE `t3` (
  `c1` int(11) DEFAULT NULL,
  `c2` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.02 sec)
```

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

13.1.8 ALTER TABLESPACE Statement

```
ALTER TABLESPACE tablespace_name
  {ADD|DROP} DATAFILE 'file_name'
  [INITIAL_SIZE [=] size]
  [WAIT]
  ENGINE [=] engine_name
```

This statement is used either to add a new data file, or to drop a data file from a tablespace.

The `ADD DATAFILE` variant enables you to specify an initial size using an `INITIAL_SIZE` clause, where *size* is measured in bytes; the default value is 134217728 (128 MB). Prior to MySQL NDB Cluster 7.2.14, this value was required to be specified using digits (Bug #13116514, Bug #16104705, Bug #62858); in MySQL NDB Cluster 7.2.14 and later, you may optionally follow *size* with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes).

Note

All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a data file with the same name, or an undo log file and a tablespace with the same name.

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

`INITIAL_SIZE` is rounded, explicitly, as for `CREATE TABLESPACE`.

Once a data file has been created, its size cannot be changed; however, you can add more data files to the tablespace using additional `ALTER TABLESPACE ... ADD DATAFILE` statements.

Using `DROP DATAFILE` with `ALTER TABLESPACE` drops the data file '*file_name*' from the tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See [Section 18.5.12.1, “NDB Cluster Disk Data Objects”](#). In addition, any data file to be dropped must previously have been added to the tablespace with `CREATE TABLESPACE` or `ALTER TABLESPACE`.

Both `ALTER TABLESPACE ... ADD DATAFILE` and `ALTER TABLESPACE ... DROP DATAFILE` require an `ENGINE` clause which specifies the storage engine used by the tablespace. Currently, the only accepted values for *engine_name* are `NDB` and `NDBCLUSTER`.

`WAIT` is parsed but otherwise ignored, and so has no effect in MySQL 5.5. It is intended for future expansion.

When `ALTER TABLESPACE ... ADD DATAFILE` is used with `ENGINE = NDB`, a data file is created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example, the following query shows all data files belonging to the tablespace named `newts`:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
```

| LOGFILE_GROUP_NAME | FILE_NAME | EXTRA |
|--------------------|--------------|----------------|
| lg_3 | newdata.dat | CLUSTER_NODE=3 |
| lg_3 | newdata.dat | CLUSTER_NODE=4 |
| lg_3 | newdata2.dat | CLUSTER_NODE=3 |
| lg_3 | newdata2.dat | CLUSTER_NODE=4 |

```
2 rows in set (0.03 sec)
```

See [Section 21.30.1, “The INFORMATION_SCHEMA FILES Table”](#).

`ALTER TABLESPACE` is useful only with Disk Data storage for NDB Cluster. See [Section 18.5.12, “NDB Cluster Disk Data Tables”](#).

13.1.9 ALTER VIEW Statement

```
ALTER
```

```
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = user]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` see [Section 13.1.20, “CREATE VIEW Statement”](#)). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is permitted only to the definer or users with the `SUPER` privilege.

13.1.10 CREATE DATABASE Statement

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
  [create_specification] ...

create_specification:
  [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
```

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the `CREATE` privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

An error occurs if the database exists and you did not specify `IF NOT EXISTS`.

`CREATE DATABASE` is not permitted within a session that has an active `LOCK TABLES` statement.

create_specification options specify database characteristics. Database characteristics are stored in the `db.opt` file in the database directory. The `CHARACTER SET` clause specifies the default database character set. The `COLLATE` clause specifies the default database collation. [Chapter 10, Character Sets, Collations, Unicode](#), discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for permissible database names are given in [Section 9.2, “Schema Object Names”](#). If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 9.2.4, “Mapping of Identifiers to File Names”](#).

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

You can also use the `mysqladmin` program to create databases. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

13.1.11 CREATE EVENT Statement

```
CREATE
  [DEFINER = user]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'string']
  DO event_body;

schedule:
  AT timestamp [+ INTERVAL interval] ...
```

```

| EVERY interval
  [STARTS timestamp [+ INTERVAL interval] ...]
  [ENDS timestamp [+ INTERVAL interval] ...]

interval:
  quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
             WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
             DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}

```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see [Section 20.4.2, “Event Scheduler Configuration”](#).

`CREATE EVENT` requires the `EVENT` privilege for the schema in which the event is to be created. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in [Section 20.6, “Stored Object Access Control”](#).

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in a database schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```

CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;

```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 9.2, “Schema Object Names”](#).

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in [Section 20.6, “Stored Object Access Control”](#). Also see that section for additional information about event security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within an event body, the `CURRENT_USER` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see [Section 6.2.14, “SQL-Based Account Activity Auditing”](#).

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `event_body` defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
-> ON SCHEDULE AT '2006-02-10 23:59:00'
-> DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
PRESERVE is set. The event was dropped immediately after
creation.
```

`CREATE EVENT` statements which are themselves invalid—for whatever reason—fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The `interval` portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in [Temporal Intervals](#), except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an `interval` as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

An `EVERY` clause may contain an optional `STARTS` clause. `STARTS` is followed by a `timestamp` value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a `timestamp` value that tells MySQL when the event should stop repeating. You may also use `+`

`INTERVAL interval with ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the `mysql.event` table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see [Section 20.4.4, “Event Metadata”](#). See also [Section 13.7.5.19, “SHOW EVENTS Statement”](#), and [Section 21.8, “The INFORMATION_SCHEMA EVENTS Table”](#).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the `DISABLE` keyword. Alternatively, you can use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see [Section 13.1.2, “ALTER EVENT Statement”](#)).

A third value may also appear in place of `ENABLE` or `DISABLE`; `DISABLE ON SLAVE` is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See [Section 17.4.1.15, “Replication of Invoked Features”](#).

You may supply a comment for an event using a `COMMENT` clause. `comment` may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See [Section 20.8, “Restrictions on Stored Programs”](#).) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, *regardless of the current server SQL mode when the event begins executing*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

Note

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
delimiter |
CREATE EVENT e_daily
ON SCHEDULE
  EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
  BEGIN
    INSERT INTO site_activity.totals (time, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
        FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
  END |
delimiter ;
```

This example uses the `delimiter` command to change the statement delimiter. See [Section 20.1, “Defining Stored Programs”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |
CREATE EVENT e
ON SCHEDULE
  EVERY 5 SECOND
DO
  BEGIN
    DECLARE v INTEGER;
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

    SET v = 0;

    WHILE v < 5 DO
      INSERT INTO t1 VALUES (0);
      UPDATE t2 SET s1 = s1 + 1;
      SET v = v + 1;
    END WHILE;
  END |
delimiter ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```
CREATE EVENT e_call_myproc
ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);
```

If an event's definer has privileges sufficient to set global system variables (see [Section 5.1.8.1, “System Variable Privileges”](#)), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permitted within stored routines, see [Section 20.2.1, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

13.1.12 CREATE FUNCTION Statement

The `CREATE FUNCTION` statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).
- For information about creating user-defined functions, see [Section 13.7.3.1, “CREATE FUNCTION Syntax for User-Defined Functions”](#).

13.1.13 CREATE INDEX Statement

```
CREATE [ONLINE | OFFLINE] [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
    [index_type]
    ON tbl_name (key_part, ...)
    [index_option] ...

key_part:
    col_name [(length)] [ASC | DESC]

index_option:
    KEY_BLOCK_SIZE [=] value
    | index_type
    | WITH PARSER parser_name
    | COMMENT 'string'

index_type:
    USING {BTREE | HASH}
```

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See [Section 13.1.17, “CREATE TABLE Statement”](#). This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. `CREATE INDEX` enables you to add indexes to existing tables.

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See [Section 13.1.7, “ALTER TABLE Statement”](#). `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

An index specification of the form (*key_part1*, *key_part2*, ...) creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example (*col1*, *col2*, *col3*) specifies a multiple-column index with index keys consisting of values from *col1*, *col2*, and *col3*.

A *key_part* specification can end with `ASC` or `DESC`. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

The following sections describe different aspects of the `CREATE INDEX` statement:

- [Column Prefix Key Parts](#)
- [Unique Indexes](#)
- [Full-Text Indexes](#)

- [Spatial Indexes](#)
- [Index Options](#)
- [Table Copying and Locking Options](#)

Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` key parts.
- Prefixes *must* be specified for `BLOB` and `TEXT` key parts. Additionally, `BLOB` and `TEXT` columns can be indexed only for `InnoDB`, `MyISAM`, and `BLACKHOLE` tables.
- Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for `InnoDB` tables or 3072 bytes if the `innodb_large_prefix` option is enabled. For `MyISAM` tables, the prefix length limit is 1000 bytes. The `NDB` storage engine does not support prefixes (see [Section 18.1.7.6, “Unsupported or Missing Features in NDB Cluster”](#)).

The statement shown here creates an index using the first 10 characters of the `name` column (assuming that `name` has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Unique Indexes

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix length. A `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`.

If a table has a `PRIMARY KEY` or `UNIQUE NOT NULL` index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in `SELECT` statements, as follows:

- `_rowid` refers to the `PRIMARY KEY` column if there is a `PRIMARY KEY` consisting of a single integer column. If there is a `PRIMARY KEY` but it does not consist of a single integer column, `_rowid` cannot be used.
- Otherwise, `_rowid` refers to the column in the first `UNIQUE NOT NULL` index if that index consists of a single integer column. If the first `UNIQUE NOT NULL` index does not consist of a single integer column, `_rowid` cannot be used.

Full-Text Indexes

`FULLTEXT` indexes are supported only for `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation.

Spatial Indexes

The `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` storage engines support spatial columns such as `POINT` and `GEOMETRY`. (Section 11.4, “Spatial Data Types”, describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns (created using `SPATIAL INDEX`) have these characteristics:

- Available only for `MyISAM` tables. Specifying `SPATIAL INDEX` for other storage engines results in an error.
- Indexed columns must be `NOT NULL`.
- Column prefix lengths are prohibited. The full width of each column is indexed.

Nonspatial indexes on spatial columns (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`) have these characteristics:

- Permitted for any storage engine that supports spatial columns except `ARCHIVE`.
- Columns can be `NULL` unless the index is a primary key.
- For each spatial column in a non-`SPATIAL` index except `POINT` columns, a column prefix length must be specified. (This is the same requirement as for indexed `BLOB` columns.) The prefix length is given in bytes.
- The index type for a non-`SPATIAL` index depends on the storage engine. Currently, B-tree is used.
- Permitted for a column that can have `NULL` values only for `InnoDB`, `MyISAM`, and `MEMORY` tables.

Index Options

Following the key part list, index options can be given. An `index_option` value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides a table-level `KEY_BLOCK_SIZE` value.

`KEY_BLOCK_SIZE` is not supported at the index level for `InnoDB` tables. See Section 13.1.17, “CREATE TABLE Statement”.

- `index_type`

Some storage engines permit you to specify an index type when creating an index. For example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

Table 13.1, “Index Types Per Storage Engine” shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an `index_type` clause in index definitions.

Table 13.1 Index Types Per Storage Engine

| Storage Engine | Permissible Index Types |
|---------------------|-------------------------|
| <code>InnoDB</code> | <code>BTREE</code> |
| <code>MyISAM</code> | <code>BTREE</code> |

| Storage Engine | Permissible Index Types |
|----------------|--------------------------------|
| MEMORY/HEAP | HASH, BTREE |
| NDB | BTREE, HASH (see note in text) |

The *index_type* clause cannot be used for FULLTEXT INDEX or SPATIAL INDEX specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

BTREE indexes are implemented by the NDB storage engine as T-tree indexes.

Note

For indexes on NDB table columns, the USING option can be specified only for a unique index or primary key. USING HASH prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an NDB table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

For unique indexes that include one or more NULL columns of an NDB table, the hash index can be used only to look up literal values, which means that IS [NOT] NULL conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more NULL columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing USING HASH when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name, but currently this cannot be specified for any storage engine.

Note

Use of the *index_type* option before the ON tbl_name clause is deprecated; support for use of the option in this position will be removed in a future MySQL release. If an *index_type* option is given in both the earlier and later positions, the final option applies.

TYPE type_name is recognized as a synonym for USING type_name. However, USING is the preferred form.

The following tables show index characteristics for the storage engines that support the *index_type* option.

Table 13.2 InnoDB Storage Engine Index Characteristics

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|-------------|------------|--------------------|------------------------------|-------------------|-----------------------|
| Primary key | BTREE | No | No | N/A | N/A |
| Unique | BTREE | Yes | Yes | Index | Index |
| Key | BTREE | Yes | Yes | Index | Index |

Table 13.3 MyISAM Storage Engine Index Characteristics

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|-------------|------------|--------------------|------------------------------|-------------------|-----------------------|
| Primary key | BTREE | No | No | N/A | N/A |
| Unique | BTREE | Yes | Yes | Index | Index |

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|--------------------------|-----------------------|--------------------|------------------------------|-------------------|-----------------------|
| Key | BTREE | Yes | Yes | Index | Index |
| FULLTEXT | N/A | Yes | Yes | Table | Table |
| SPATIAL | N/A | No | No | N/A | N/A |

Table 13.4 MEMORY Storage Engine Index Characteristics

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|-------------|-----------------------|--------------------|------------------------------|-------------------|-----------------------|
| Primary key | BTREE | No | No | N/A | N/A |
| Unique | BTREE | Yes | Yes | Index | Index |
| Key | BTREE | Yes | Yes | Index | Index |
| Primary key | HASH | No | No | N/A | N/A |
| Unique | HASH | Yes | Yes | Index | Index |
| Key | HASH | Yes | Yes | Index | Index |

Table 13.5 NDB Storage Engine Index Characteristics

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|-------------|-----------------------|--------------------|------------------------------|--------------------|-----------------------|
| Primary key | BTREE | No | No | Index | Index |
| Unique | BTREE | Yes | Yes | Index | Index |
| Key | BTREE | Yes | Yes | Index | Index |
| Primary key | HASH | No | No | Table (see note 1) | Table (see note 1) |
| Unique | HASH | Yes | Yes | Table (see note 1) | Table (see note 1) |
| Key | HASH | Yes | Yes | Table (see note 1) | Table (see note 1) |

Table note:

1. If [USING HASH](#) is specified that prevents creation of an implicit ordered index.

- [WITH PARSER *parser_name*](#)

This option can be used only with [FULLTEXT](#) indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. See [Section 24.2, "The MySQL Plugin API"](#), for details on creating plugins.

- [COMMENT '*string*'](#)

Index definitions can include an optional comment of up to 1024 characters.

Table Copying and Locking Options

Indexes on variable-width columns of [NDBCLUSTER](#) tables are created online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the *same* API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In standard MySQL 5.5 releases, it is not possible to override the server when it determines that an index is to be created without table copying. In NDB Cluster, you can create indexes offline (which causes the table to be locked to all API nodes in the cluster) using the [OFFLINE](#) keyword. The rules and limitations governing [CREATE OFFLINE INDEX](#) and [CREATE ONLINE INDEX](#) are the same

as for `ALTER OFFLINE TABLE ... ADD INDEX` and `ALTER ONLINE TABLE ... ADD INDEX`. You cannot cause the noncopying creation of an index that would normally be created offline by using the `ONLINE` keyword: If it is not possible to perform the `CREATE INDEX` operation without table copying, the server ignores the `ONLINE` keyword. For more information, see [Section 18.5.13, “Online Operations with ALTER TABLE in NDB Cluster”](#).

The `ONLINE` and `OFFLINE` keywords are available only in NDB Cluster; attempting to use these keywords in standard MySQL Server 5.5 releases results in a syntax error.

13.1.14 CREATE LOGFILE GROUP Statement

```
CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
  [INITIAL_SIZE [=] initial_size]
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  [REDO_BUFFER_SIZE [=] redo_buffer_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] 'string']
  ENGINE [=] engine_name
```

This statement creates a new log file group named `logfile_group` having a single UNDO file named '`undo_file`'. A `CREATE LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. For rules covering the naming of log file groups, see [Section 9.2, “Schema Object Names”](#).

Note

All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

In MySQL NDB Cluster 7.2, you can have only one log file group per Cluster at any given time. (See Bug #16386)

The optional `INITIAL_SIZE` parameter sets the UNDO file's initial size; if not specified, it defaults to `128M` (128 megabytes). The optional `UNDO_BUFFER_SIZE` parameter sets the size used by the UNDO buffer for the log file group; The default value for `UNDO_BUFFER_SIZE` is `8M` (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. In MySQL NDB Cluster 7.2.14 and later, you may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes). Prior to MySQL NDB Cluster 7.2.14, the values for these options could only be specified using digits. (Bug #13116514, Bug #16104705, Bug #62858)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

The maximum permitted for `UNDO_BUFFER_SIZE` is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB).

The `ENGINE` option determines the storage engine to be used by this log file group, with `engine_name` being the name of the storage engine. In MySQL 5.5, this must be `NDB` (or `NDBCLUSTER`). If `ENGINE` is not set, MySQL tries to use the engine specified by the `default_storage_engine` server system variable (formerly `storage_engine`). In any case, if the engine is not specified as `NDB` or

`NDBCLUSTER`, the `CREATE LOGFILE GROUP` statement appears to succeed but actually fails to create the log file group, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
->     ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message
+-----+-----+-----+
| Error | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
->     ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
->     ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
```

The fact that the `CREATE LOGFILE GROUP` statement does not actually return an error when a non-NDB storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of NDB Cluster.

`REDO_BUFFER_SIZE`, `NODEGROUP`, `WAIT`, and `COMMENT` are parsed but ignored, and so have no effect in MySQL 5.5. These options are intended for future expansion.

When used with `ENGINE [=] NDB`, a log file group and associated `UNDO` log file are created on each Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'undo_10.dat';
+-----+-----+-----+
| LOGFILE_GROUP_NAME | LOGFILE_GROUP_NUMBER | EXTRA
+-----+-----+-----+
| lg_3               | 11                   | CLUSTER_NODE=3
| lg_3               | 11                   | CLUSTER_NODE=4
+-----+-----+-----+
2 rows in set (0.06 sec)
```

`CREATE LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. See [Section 18.5.12, “NDB Cluster Disk Data Tables”](#).

13.1.15 CREATE PROCEDURE and CREATE FUNCTION Statements

```
CREATE
[DEFINER = user]
PROCEDURE sp_name ([proc_parameter[,...]]
[characteristic ...] routine_body

CREATE
[DEFINER = user]
FUNCTION sp_name ([func_parameter[,...]])
RETURNS type
[characteristic ...] routine_body

proc_parameter:
[ IN | OUT | INOUT ] param_name type

func_parameter:
param_name type

type:
Any valid MySQL data type
```

```

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }

routine_body:
  Valid SQL routine statement

```

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support UDFs (user-defined functions). See [Section 24.4, “Adding Functions to MySQL”](#). A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See [Section 9.2.5, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see [Section 13.2.1, “CALL Statement”](#)). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

`CREATE PROCEDURE` and `CREATE FUNCTION` require the `CREATE ROUTINE` privilege. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in [Section 20.6, “Stored Object Access Control”](#). If binary logging is enabled, `CREATE FUNCTION` might require the `SUPER` privilege, as discussed in [Section 20.7, “Stored Program Binary Logging”](#).

By default, MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 20.2.2, “Stored Routines and MySQL Privileges”](#).

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case-sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `OUT` or `INOUT` parameter. If you are calling the procedure from within a trigger, you can also pass `NEW.col_name` as an `OUT` or `INOUT` parameter.

For information about the effect of unhandled conditions on procedure parameters, see [Section 13.6.7.5, “Condition Handling and OUT or INOUT Parameters”](#).

Routine parameters cannot be referenced in statements prepared within the routine; see [Section 20.8, “Restrictions on Stored Programs”](#).

The following example shows a simple stored procedure that uses an `OUT` parameter:

```
mysql> delimiter //

mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See [Section 20.1, “Defining Stored Programs”](#).

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by a `CHARACTER SET` specification.

The *routine_body* consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in [Section 13.6, “Compound-Statements”](#). In practice, stored functions tend to use compound statements, unless the body consists of a single `RETURN` statement.

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see [Section 20.8, “Restrictions on Stored Programs”](#).

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 13.2.1, “CALL Statement”](#).

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, *regardless of the current server SQL mode when the routine begins executing*.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See [Section 20.7, “Stored Program Binary Logging”](#).

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.
- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in [Section 20.6, “Stored Object Access Control”](#). Also see that section for additional information about stored routine security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within the body of a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, the `CURRENT_USER` function returns the routine's `DEFINER` value. For information about user auditing within stored routines, see [Section 6.2.14, “SQL-Based Account Activity Auditing”](#).

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` system table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` system table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
```

```
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` system table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if `CHARACTER SET` is included in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

Prior to MySQL 5.5.3, if there is a `CHARACTER SET` attribute in the declaration, the `COLLATE` attribute is not supported, and the character set's default collation is used. (This includes use of `BINARY`, which in this context specifies the binary collation of the character set.) If there is no `CHARACTER SET` attribute, the database character set and its default collation (rather than the database collation) are used.

If `CHARACTER SET` and `COLLATE` are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit `CHARACTER SET` and a `COLLATE` attribute for character data parameters.

If you change the database default character set or collation, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see [Section 10.3.3, "Database Character Set and Collation"](#).

13.1.16 CREATE SERVER Statement

```
CREATE SERVER server_name
  FOREIGN DATA WRAPPER wrapper_name
  OPTIONS (option [, option] ...)

option:
{ HOST character-literal
| DATABASE character-literal
| USER character-literal
| PASSWORD character-literal
| SOCKET character-literal
| OWNER character-literal
| PORT numeric-literal }
```

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The `wrapper_name` is an identifier and may be quoted with single quotation marks.

For each *option* you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

Note

The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a `FEDERATED` table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see [Section 15.9, “The FEDERATED Storage Engine”](#).

`CREATE SERVER` causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`CREATE SERVER` is not written to the binary log, regardless of the logging format that is in use.

13.1.17 CREATE TABLE Statement

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    (create_definition,...)
    [table_options]
    [partition_options]

```

CREATE TABLE creates a table with the given name. You must have the **CREATE** privilege for the table.

By default, tables are created in the default database, using the **InnoDB** storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. **InnoDB** permits up to 4 billion tables.

For information about the physical representation of a table, see [Section 13.1.17.2, “Files Created by CREATE TABLE”](#).

The original **CREATE TABLE** statement, including all specifications and table options are stored by MySQL when the table is created. For more information, see [Section 13.1.17.1, “CREATE TABLE Statement Retention”](#).

There are several aspects to the **CREATE TABLE** statement, described under the following topics in this section:

- [Table Name](#)
- [Temporary Tables](#)
- [Table Cloning and Copying](#)
- [Column Data Types and Attributes](#)
- [Indexes and Foreign Keys](#)
- [Table Options](#)
- [Table Partitioning](#)

Table Name

- *tbl_name*

The table name can be specified as *db_name.tbl_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

Rules for permissible table names are given in [Section 9.2, “Schema Object Names”](#).

- `IF NOT EXISTS`

Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

Temporary Tables

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see [Section 13.1.17.3, “CREATE TEMPORARY TABLE Statement”](#).

Table Cloning and Copying

- `LIKE`

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see [Section 13.1.17.4, “CREATE TABLE ... LIKE Statement”](#).

- `[AS] query_expression`

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see [Section 13.1.17.5, “CREATE TABLE ... SELECT Statement”](#).

- `IGNORE|REPLACE`

The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

For more information, see [Section 13.1.17.5, “CREATE TABLE ... SELECT Statement”](#).

Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

- *data_type*

data_type represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see [Chapter 11, Data Types](#).

- Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. `DEFAULT` does not apply to the `BLOB` or `TEXT` types.
- Character data types (`CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, `SET`, and any synonyms) can include `CHARACTER SET` to specify the character set for the column. `CHARSET` is a synonym for

CHARACTER SET. A collation for the character set can be specified with the **COLLATE** attribute, along with any other attributes. For details, see [Chapter 10, Character Sets, Collations, Unicode](#). Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.5 interprets length specifications in character column definitions in characters. Lengths for **BINARY** and **VARBINARY** are in bytes.

- For **CHAR**, **VARCHAR**, **BINARY**, and **VARBINARY** columns, indexes can be created that use only the leading part of column values, using *col_name(length)* syntax to specify an index prefix length. **BLOB** and **TEXT** columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for **CHAR**, **VARCHAR**, and **TEXT** columns, and the first *length* bytes of each column value for **BINARY**, **VARBINARY**, and **BLOB** columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see [Section 13.1.13, “CREATE INDEX Statement”](#).

Only the **InnoDB** and **MyISAM** storage engines support indexing on **BLOB** and **TEXT** columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

- **NOT NULL | NULL**

If neither **NULL** nor **NOT NULL** is specified, the column is treated as though **NULL** had been specified.

In MySQL 5.5, only the **InnoDB**, **MyISAM**, and **MEMORY** storage engines support indexes on columns that can have **NULL** values. In other cases, you must declare indexed columns as **NOT NULL** or an error results.

- **DEFAULT**

Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit **DEFAULT** value, see [Section 11.5, “Data Type Default Values”](#).

CREATE TABLE fails if a date-valued default is not correct according to the **NO_ZERO_IN_DATE** SQL mode, even if strict SQL mode is not enabled. For example, `c1 DATE DEFAULT '2010-00-00'` causes **CREATE TABLE** to fail with `Invalid default value for 'c1'`.

- **AUTO_INCREMENT**

An integer or floating-point column can have the additional attribute **AUTO_INCREMENT**. When you insert a value of **NULL** (recommended) or **0** into an indexed **AUTO_INCREMENT** column, the column is set to the next sequence value. Typically this is *value+1*, where *value* is the largest value for the column currently in the table. **AUTO_INCREMENT** sequences begin with **1**.

To retrieve an **AUTO_INCREMENT** value after inserting a row, use the **LAST_INSERT_ID()** SQL function or the **mysql_insert_id()** C API function. See [Section 12.15, “Information Functions”](#), and [Section 23.7.6.37, “mysql_insert_id\(\)”](#).

If the **NO_AUTO_VALUE_ON_ZERO** SQL mode is enabled, you can store **0** in **AUTO_INCREMENT** columns as **0** without generating a new sequence value. See [Section 5.1.10, “Server SQL Modes”](#).

There can be only one **AUTO_INCREMENT** column per table, it must be indexed, and it cannot have a **DEFAULT** value. An **AUTO_INCREMENT** column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to

avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains 0.

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to 0. See [Section 5.1.7, “Server System Variables”](#).

For information about `InnoDB` and `AUTO_INCREMENT`, see [Section 14.9.1.4, “AUTO_INCREMENT Handling in InnoDB”](#). For information about `AUTO_INCREMENT` and MySQL Replication, see [Section 17.4.1.1, “Replication and AUTO_INCREMENT”](#).

- `COMMENT`

A comment for a column can be specified with the `COMMENT` option, up to 1024 characters long (255 characters before MySQL 5.5.3). The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements.

- `COLUMN_FORMAT`

In `NDB Cluster`, it is also possible to specify a data storage format for individual columns of `NDB` tables using `COLUMN_FORMAT`. Permissible column formats are `FIXED`, `DYNAMIC`, and `DEFAULT`. `FIXED` is used to specify fixed-width storage, `DYNAMIC` permits the column to be variable-width, and `DEFAULT` causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a `ROW_FORMAT` specifier).

For `NDB` tables, the default value for `COLUMN_FORMAT` is `DEFAULT`.

In `NDB Cluster`, the maximum possible offset for a column defined with `COLUMN_FORMAT=FIXED` is 8188 bytes. For more information and possible workarounds, see [Section 18.1.7.5, “Limits Associated with Database Objects in NDB Cluster”](#).

`COLUMN_FORMAT` currently has no effect on columns of tables using storage engines other than `NDB`. In MySQL 5.5 and later, `COLUMN_FORMAT` is silently ignored.

- `STORAGE`

For `NDB` tables, it is possible to specify whether the column is stored on disk or in memory by using a `STORAGE` clause. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. The `CREATE TABLE` statement used must still include a `TABLESPACE` clause:

```
mysql> CREATE TABLE t1 (
->   c1 INT STORAGE DISK,
->   c2 INT STORAGE MEMORY
-> ) ENGINE NDB;
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)

mysql> CREATE TABLE t1 (
->   c1 INT STORAGE DISK,
->   c2 INT STORAGE MEMORY
-> ) TABLESPACE ts_1 ENGINE NDB;
```

```
Query OK, 0 rows affected (1.06 sec)
```

For NDB tables, `STORAGE DEFAULT` is equivalent to `STORAGE MEMORY`.

The `STORAGE` clause has no effect on tables using storage engines other than NDB. The `STORAGE` keyword is supported only in the build of `mysqld` that is supplied with NDB Cluster; it is not recognized in any other version of MySQL, where any attempt to use the `STORAGE` keyword causes a syntax error.

Indexes and Foreign Keys

Several keywords apply to creation of indexes and foreign keys. For general background in addition to the following descriptions, see [Section 13.1.13, “CREATE INDEX Statement”](#), and [Section 13.1.17.6, “FOREIGN KEY Constraints”](#).

- `CONSTRAINT symbol`

The `CONSTRAINT symbol` clause may be given to name a constraint. If the clause is not given, or a *symbol* is not included following the `CONSTRAINT` keyword, MySQL automatically generates a constraint name. The *symbol* value, if used, must be unique per schema (database), per constraint type. A duplicate *symbol* results in an error. See also the discussion about length limits of generated constraint identifiers at [Section 9.2.1, “Identifier Length Limits”](#).

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema.

- `PRIMARY KEY`

A unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. The name of a `PRIMARY KEY` is always `PRIMARY`, which thus cannot be used as the name for any other kind of index.

If you do not have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

In `InnoDB` tables, keep the `PRIMARY KEY` short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See [Section 14.9.2.1, “Clustered and Secondary Indexes”](#).)

In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.

A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(key_part, ...)` clause.

If a table has a `PRIMARY KEY` or `UNIQUE NOT NULL` index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in `SELECT` statements, as described in [Unique Indexes](#).

In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2, _3, ...`) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See [Section 13.7.5.23, “SHOW INDEX Statement”](#).

- `KEY` | `INDEX`

KEY is normally a synonym for **INDEX**. The key attribute **PRIMARY KEY** can also be specified as just **KEY** when given in a column definition. This was implemented for compatibility with other database systems.

- **UNIQUE**

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in **SELECT** statements, as described in [Unique Indexes](#).

- **FULLTEXT**

A **FULLTEXT** index is a special type of index used for full-text searches. Only the **MyISAM** storage engine supports **FULLTEXT** indexes. They can be created only from **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation. A **WITH PARSER** clause can be specified as an *index_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for **FULLTEXT** indexes. See [Section 24.2, “The MySQL Plugin API”](#), for details on creating plugins.

- **SPATIAL**

You can create **SPATIAL** indexes on spatial data types. Spatial types are supported only for **MyISAM** tables and indexed columns must be declared as **NOT NULL**. See [Section 11.4, “Spatial Data Types”](#).

- **FOREIGN KEY**

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see *reference_definition*, and *reference_option*.

Partitioned tables employing the **InnoDB** storage engine do not support foreign keys. See [Section 19.5, “Restrictions and Limitations on Partitioning”](#), for more information.

- **CHECK**

The **CHECK** clause is parsed but ignored by all storage engines.

- *key_part*

- A *key_part* specification can end with **ASC** or **DESC**. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.
- Prefixes, defined by the *length* attribute, can be up to 767 bytes long for **InnoDB** tables or 3072 bytes if the `innodb_large_prefix` option is enabled. For **MyISAM** tables, the prefix length limit is 1000 bytes.

Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in **CREATE TABLE**, **ALTER TABLE**, and **CREATE INDEX** statements are interpreted as number of characters for nonbinary string types (**CHAR**, **VARCHAR**, **TEXT**) and number of bytes for binary string types

([BINARY](#), [VARBINARY](#), [BLOB](#)). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- *index_type*

Some storage engines permit you to specify an index type when creating an index. The syntax for the *index_type* specifier is `USING type_name`.

Example:

```
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for `USING` is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and will be removed in a future MySQL release.

- *index_option*

index_option values specify additional options for an index.

- `KEY_BLOCK_SIZE`

For [MyISAM](#) tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

For information about the table-level `KEY_BLOCK_SIZE` attribute, see [Table Options](#).

- `WITH PARSER`

A `WITH PARSER` clause can be specified as an *index_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for `FULLTEXT` indexes. See [Section 24.2, “The MySQL Plugin API”](#), for details on creating plugins.

- `COMMENT`

As of MySQL 5.5.3, index definitions can include an optional comment of up to 1024 characters.

For more information about permissible *index_option* values, see [Section 13.1.13, “CREATE INDEX Statement”](#). For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

- *reference_definition*

For *reference_definition* syntax details and examples, see [Section 13.1.17.6, “FOREIGN KEY Constraints”](#).

[InnoDB](#) tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both `ON DELETE` and `ON UPDATE` actions on foreign keys. For more detailed information and examples, see [Section 13.1.17.6, “FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. See [Section 1.7.2.3, “FOREIGN KEY Constraint Differences”](#).

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including [InnoDB](#), recognizes or enforces the `MATCH` clause

used in referential integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. `InnoDB` essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, `InnoDB` does not enforce any requirement that the referenced columns be declared `UNIQUE` or `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only keys that are both `UNIQUE` (or `PRIMARY`) and `NOT NULL`.

MySQL parses but ignores “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification.

- *reference_option*

For information about the `RESTRICT`, `CASCADE`, `SET NULL`, `NO ACTION`, and `SET DEFAULT` options, see [Section 13.1.17.6, “FOREIGN KEY Constraints”](#).

Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- `ENGINE`

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name `'DEFAULT'` is equivalent to specifying the default storage engine name.

| Storage Engine | Description |
|----------------------|---|
| <code>InnoDB</code> | Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 14, <i>The InnoDB Storage Engine</i> , and in particular Section 14.1, “Introduction to InnoDB” if you have MySQL experience but are new to <code>InnoDB</code> . |
| <code>MyISAM</code> | The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 15.3, “The MyISAM Storage Engine” . |
| <code>MEMORY</code> | The data for this storage engine is stored only in memory. See Section 15.4, “The MEMORY Storage Engine” . |
| <code>CSV</code> | Tables that store rows in comma-separated values format. See Section 15.5, “The CSV Storage Engine” . |
| <code>ARCHIVE</code> | The archiving storage engine. See Section 15.6, “The ARCHIVE Storage Engine” . |

| Storage Engine | Description |
|----------------|---|
| EXAMPLE | An example engine. See Section 15.10, “The EXAMPLE Storage Engine” . |
| FEDERATED | Storage engine that accesses remote tables. See Section 15.9, “The FEDERATED Storage Engine” . |
| HEAP | This is a synonym for MEMORY. |
| MERGE | A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 15.8, “The MERGE Storage Engine” . |
| NDBCLUSTER | Clustered, fault-tolerant, memory-based tables. Also known as NDB. See Chapter 18, MySQL NDB Cluster 7.2 . |

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is MyISAM. For example, if a table definition includes the `ENGINE=INNODB` option but the MySQL server does not support INNODB tables, the table is created as a MyISAM table. This makes it possible to have a replication setup where you have transactional tables on the master but tables created on the slave are nontransactional (to get more speed). In MySQL 5.5, a warning occurs if the storage engine specification is not honored.

Engine substitution can be controlled by the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.10, “Server SQL Modes”](#).

Note

The older `TYPE` option was synonymous with `ENGINE`. `TYPE` was deprecated in MySQL 4.0 and removed in MySQL 5.5. *When upgrading to MySQL 5.5 or later, you must convert existing applications that rely on `TYPE` to use `ENGINE` instead.*

- `AUTO_INCREMENT`

The initial `AUTO_INCREMENT` value for the table. In MySQL 5.5, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value. The value cannot be set lower than the maximum value currently in the column.

- `AVG_ROW_LENGTH`

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a MyISAM table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for MyISAM data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` system variable. (See [Section 5.1.7, “Server System Variables”](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- `[DEFAULT] CHARACTER SET`

Specifies a default character set for the table. `CHARSET` is a synonym for `CHARACTER SET`. If the character set name is `DEFAULT`, the database character set is used.

- `CHECKSUM`

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. (`MyISAM` only.)

- `[DEFAULT] COLLATE`

Specifies a default collation for the table.

- `COMMENT`

A comment for the table, up to 2048 characters long (60 characters before MySQL 5.5.3).

- `CONNECTION`

The connection string for a `FEDERATED` table.

Note

Older versions of MySQL used a `COMMENT` option for the connection string.

- `DATA DIRECTORY, INDEX DIRECTORY`

By using `DATA DIRECTORY='directory'` or `INDEX DIRECTORY='directory'` you can specify where the `MyISAM` storage engine should put a table's data file and index file. The directory must be the full path name to the directory, not a relative path.

As of MySQL 5.5.54, you must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` table option.

Important

Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See [Section 8.12.3.2, “Using Symbolic Links for MyISAM Tables on Unix”](#), for more complete information.

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, start the server with the `--keep_files_on_create` option, in which case `MyISAM` will not overwrite existing files and returns an error instead.

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

Important

You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- `DELAY_KEY_WRITE`

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in [Section 5.1.7, “Server System Variables”](#). (`MyISAM` only.)

- `INSERT_METHOD`

If you want to insert data into a `MERGE` table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for `MERGE` tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See [Section 15.8, “The MERGE Storage Engine”](#).

- `KEY_BLOCK_SIZE`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

For `InnoDB` tables, `KEY_BLOCK_SIZE` specifies the [page](#) size in kilobytes to use for [compressed InnoDB](#) tables. The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by `InnoDB` if necessary. Valid `KEY_BLOCK_SIZE` values include 0, 1, 2, 4, 8, and 16. A value of 0 represents the default compressed page size, which is half of the `InnoDB` page size.

Oracle recommends enabling `innodb_strict_mode` when specifying `KEY_BLOCK_SIZE` for `InnoDB` tables. When `innodb_strict_mode` is enabled, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. If `innodb_strict_mode` is disabled, an invalid `KEY_BLOCK_SIZE` value results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

The `Create_options` column in response to `SHOW TABLE STATUS` reports the originally specified `KEY_BLOCK_SIZE` option, as does `SHOW CREATE TABLE`.

`InnoDB` only supports `KEY_BLOCK_SIZE` at the table level.

- `MAX_ROWS`

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

The `NDB` storage engine treats this value as a maximum. If you plan to create very large `NDB` Cluster tables (containing millions of rows), you should use this option to insure that `NDB` allocates sufficient number of index slots in the hash table used for storing hashes of the table's primary keys by setting `MAX_ROWS = 2 * rows`, where `rows` is the number of rows that you expect to insert into the table.

The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- `MIN_ROWS`

The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- `PACK_KEYS`

Takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of

keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- `PASSWORD`

This option is unused. If you have a need to scramble your `.frm` files and make them unusable to any other MySQL server, please contact our sales department.

- `ROW_FORMAT`

Defines the physical format in which the rows are stored.

When executing a `CREATE TABLE` statement with `strict mode` disabled, if you specify a row format that is not supported by the storage engine that is used for the table, the table is created using that storage engine's default row format. The information reported in the `Row_format` column in response to `SHOW TABLE STATUS` is the actual row format used. This may differ from the value in the `Create_options` column because the original `CREATE TABLE` definition is retained during creation. `SHOW CREATE TABLE` also reports the row format used in the original `CREATE TABLE` statement.

Row format choices differ depending on the storage engine used for the table.

For `InnoDB` tables:

- Rows are stored in compact format (`ROW_FORMAT=COMPACT`) by default.
- The noncompact format used in older versions of MySQL can still be requested by specifying `ROW_FORMAT=REDUNDANT`.
- To enable compression for `InnoDB` tables, specify `ROW_FORMAT=COMPRESSED` and follow the procedures in [Section 14.12, “InnoDB Table Compression”](#).
- For more efficient `InnoDB` storage of data types, especially `BLOB` types, specify `ROW_FORMAT=DYNAMIC` and follow the procedures in [DYNAMIC Row Format](#). Both the `COMPRESSED` and `DYNAMIC` row formats require creating the table with the configuration settings `innodb_file_per_table=1` and `innodb_file_format=barracuda`.
- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.
- `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, `InnoDB` issues a warning and assumes

`ROW_FORMAT=COMPACT`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, InnoDB returns an error.

- For additional information about InnoDB row formats, see [Section 14.14, “InnoDB Row Formats”](#).

For MyISAM tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See [Section 15.3.3, “MyISAM Table Storage Formats”](#).

- `TABLESPACE`

The `TABLESPACE` and `STORAGE` table options are employed only with `NDBCLUSTER` tables. The tablespace named `tablespace_name` must already have been created using `CREATE TABLESPACE`. `STORAGE` determines the type of storage used (disk or memory), and can be either `DISK` or `MEMORY`.

`TABLESPACE ... STORAGE DISK` assigns a table to an NDB Cluster Disk Data tablespace. See [Section 18.5.12, “NDB Cluster Disk Data Tables”](#), for more information.

Important

A `STORAGE` clause cannot be used in a `CREATE TABLE` statement without a `TABLESPACE` clause.

- `UNION`

Used to access a collection of identical MyISAM tables as one. This works only with `MERGE` tables. See [Section 15.8, “The MERGE Storage Engine”](#).

You must have `SELECT`, `UPDATE`, and `DELETE` privileges for the tables you map to a `MERGE` table.

Note

Formerly, all tables used had to be in the same database as the `MERGE` table itself. This restriction no longer applies.

Table Partitioning

`partition_options` can be used to control partitioning of the table created with `CREATE TABLE`.

Not all options shown in the syntax for `partition_options` at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 19, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

- `PARTITION BY`

If used, a `partition_options` clause begins with `PARTITION BY`. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to `num`, where `num` is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 13.1.7, “ALTER TABLE Statement”](#). For more detailed descriptions and examples, see [Section 19.3, “Partition Management”](#).

**Note**

The expression (*expr*) used in a `PARTITION BY` clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

- `HASH(expr)`

Hashes one or more columns to create a key for placing and locating rows. *expr* is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
PARTITION BY HASH ( YEAR(col3) );
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

`PARTITION BY HASH` uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 19.2.4, “HASH Partitioning”](#).

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see [Section 19.2.4.1, “LINEAR HASH Partitioning”](#).

- `KEY [ALGORITHM={1|2}] (column_list)`: This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column_list* argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY KEY(col3)
PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see [Section 19.2.4.1, “LINEAR HASH Partitioning”](#), and [Section 19.2.5, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR KEY(col3)
PARTITIONS 5;
```

The `ALGORITHM={1|2}` option is supported with `[SUB]PARTITION BY [LINEAR] KEY` beginning with MySQL 5.5.31. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#).

`mysqldump` in MySQL 5.5.31 and later writes this option encased in versioned comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50531 ALGORITHM = 1 */ /*!50100 ()
```

This causes MySQL 5.5.30 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.5.31 or later MySQL 5.5 server where you use tables that are partitioned or subpartitioned by `KEY` into a MySQL 5.6 server previous to version 5.6.11, be sure to consult [Changes in MySQL 5.6](#), before proceeding. (The information found there also applies if you are loading a dump containing `KEY` partitioned or subpartitioned tables made from a MySQL 5.6.11 or later server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.5.31 and later, `ALGORITHM=1` is shown when necessary in the output of `SHOW CREATE TABLE` using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is always omitted from `SHOW CREATE TABLE` output, even if this option was specified when creating the original table.

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- `RANGE(expr)`

In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

Note

For tables partitioned by `RANGE`, `VALUES LESS THAN` must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 5.5, you can overcome this limitation in a table that is defined using `PARTITION BY RANGE COLUMNS`, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

| Partition Number: | Years Range: |
|-------------------|------------------|
| 0 | 1990 and earlier |
| 1 | 1991 to 1994 |
| 2 | 1995 to 1998 |
| 3 | 1999 to 2002 |
| 4 | 2003 to 2005 |
| 5 | 2006 and later |

A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```
CREATE TABLE t1 (
  year_col INT,
  some_data INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2002),
  PARTITION p4 VALUES LESS THAN (2006),
  PARTITION p5 VALUES LESS THAN MAXVALUE
```

```
);
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- `RANGE COLUMNS(column_list)`

This variant on `RANGE` was introduced in MySQL 5.5.0 to facilitate partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...` You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```
CREATE TABLE rc (
  a INT NOT NULL,
  b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (10,5),
  PARTITION p1 VALUES LESS THAN (20,10),
  PARTITION p2 VALUES LESS THAN (50,MAXVALUE),
  PARTITION p3 VALUES LESS THAN (65,MAXVALUE),
  PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see [Section 19.2.1, “RANGE Partitioning”](#), and [Section 19.4, “Partition Pruning”](#).

- `LIST(expr)`

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or

country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to [RANGE](#), except that only [VALUES IN](#) may be used to specify permissible values for each partition.

[VALUES IN](#) is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using [VALUES IN](#). You cannot use [VALUES LESS THAN](#) with [PARTITION BY LIST](#).

Note

For tables partitioned by [LIST](#), the value list used with [VALUES IN](#) must consist of integer values only. In MySQL 5.5, you can overcome this limitation using partitioning by [LIST COLUMNS](#), which is described later in this section.

- [LIST COLUMNS\(*column_list*\)](#)

This variant on [LIST](#) was introduced in MySQL 5.5.0 to facilitate partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as [WHERE a = 5 AND b = 5](#) or [WHERE a = 1 AND b = 10 AND c = 5](#)). It enables you to specify values in multiple columns by using a list of columns in the [COLUMNS](#) clause and a set of column values in each [PARTITION ... VALUES IN \(*value_list*\)](#) partition definition clause.

The rules governing regarding data types for the column list used in [LIST COLUMNS\(*column_list*\)](#) and the value list used in [VALUES IN\(*value_list*\)](#) are the same as those for the column list used in [RANGE COLUMNS\(*column_list*\)](#) and the value list used in [VALUES LESS THAN\(*value_list*\)](#), respectively, except that in the [VALUES IN](#) clause, [MAXVALUE](#) is not permitted, and you may use [NULL](#).

There is one important difference between the list of values used for [VALUES IN](#) with [PARTITION BY LIST COLUMNS](#) as opposed to when it is used with [PARTITION BY LIST](#). When used with [PARTITION BY LIST COLUMNS](#), each element in the [VALUES IN](#) clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the [COLUMNS](#) clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the [column_list](#) and in the elements making up the [value_list](#) is 16.

The table defined by the following [CREATE TABLE](#) statement provides an example of a table using [LIST COLUMNS](#) partitioning:

```
CREATE TABLE lc (
  a INT NULL,
  b INT NULL
)
PARTITION BY LIST COLUMNS(a,b) (
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
  PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- `PARTITIONS num`

The number of partitions may optionally be specified with a `PARTITIONS num` clause, where *num* is the number of partitions. If both this clause *and* any `PARTITION` clauses are used, *num* must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

**Note**

Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- `SUBPARTITION BY`

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

- Rigorous checking of the value used in `PARTITIONS` or `SUBPARTITIONS` clauses is applied and this value must adhere to the following rules:
 - The value must be a positive, nonzero integer.
 - No leading zeros are permitted.
 - The value must be an integer literal, and cannot not be an expression. For example, `PARTITIONS 0.2E+01` is not permitted, even though `0.2E+01` evaluates to `2`. (Bug #15890)
- *partition_definition*

Each partition may be individually defined using a *partition_definition* clause. The individual parts making up this clause are as follows:

- `PARTITION partition_name`

Specifies a logical name for the partition.

- `VALUES`

For range partitioning, each partition must include a `VALUES LESS THAN` clause; for list partitioning, you must specify a `VALUES IN` clause for each partition. This is used to determine

which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 19, *Partitioning*](#), for syntax examples.

- **COMMENT**

An optional **COMMENT** clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

- **DATA DIRECTORY** and **INDEX DIRECTORY**

DATA DIRECTORY and **INDEX DIRECTORY** may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the *data_dir* and the *index_dir* must be absolute system path names.

As of MySQL 5.5.54, you must have the **FILE** privilege to use the **DATA DIRECTORY** or **INDEX DIRECTORY** partition option.

Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
  DATA DIRECTORY = '/var/appdata/95/data'
  INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
  DATA DIRECTORY = '/var/appdata/96/data'
  INDEX DIRECTORY = '/var/appdata/96/idx',
  PARTITION p2001 VALUES IN (1997, 2001, 2005)
  DATA DIRECTORY = '/var/appdata/97/data'
  INDEX DIRECTORY = '/var/appdata/97/idx',
  PARTITION p2002 VALUES IN (1998, 2002, 2006)
  DATA DIRECTORY = '/var/appdata/98/data'
  INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

DATA DIRECTORY and **INDEX DIRECTORY** behave in the same way as in the **CREATE TABLE** statement's *table_option* clause as used for **MyISAM** tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the **DATA DIRECTORY** and **INDEX DIRECTORY** options are not supported for individual partitions or subpartitions. These options are ignored on Windows, except that a warning is generated. (Bug #30459)

Note

The **DATA DIRECTORY** and **INDEX DIRECTORY** options are ignored for creating partitioned tables if **NO_DIR_IN_CREATE** is in effect. (Bug #24633)

- **MAX_ROWS** and **MIN_ROWS**

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for *max_number_of_rows* and *min_number_of_rows* must be positive

integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

- **TABLESPACE**

The optional **TABLESPACE** clause may be used to designate a tablespace for the partition. Used for NDB Cluster only.

- **[STORAGE] ENGINE**

The partitioning handler accepts a **[STORAGE] ENGINE** option for both **PARTITION** and **SUBPARTITION**. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error **ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL**. We expect to lift this restriction on partitioning in a future MySQL release.

- **NODEGROUP**

The **NODEGROUP** option can be used to make this partition act as part of the node group identified by *node_group_id*. This option is applicable only to NDB Cluster.

- *subpartition_definition*

The partition definition may optionally contain one or more *subpartition_definition* clauses. Each of these consists at a minimum of the **SUBPARTITION name**, where *name* is an identifier for the subpartition. Except for the replacement of the **PARTITION** keyword with **SUBPARTITION**, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by **HASH** or **KEY**, and can be done only on **RANGE** or **LIST** partitions. See [Section 19.2.6, “Subpartitioning”](#).

13.1.17.1 CREATE TABLE Statement Retention

The original **CREATE TABLE** statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an **ALTER TABLE** statement, the original table options specified are retained. This enables you to change between **InnoDB** and **MyISAM** table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured (such as the **ROW_FORMAT**), the active table definition (accessible through **DESCRIBE** or with **SHOW TABLE STATUS**) and the table creation string (accessible through **SHOW CREATE TABLE**) will report different values.

13.1.17.2 Files Created by CREATE TABLE

MySQL represents each table by an **.frm** table format (definition) file in the database directory. The storage engine for the table might create other files as well.

For **InnoDB** tables, the file storage is controlled by the **innodb_file_per_table** configuration option. For each **InnoDB** table created when this option is turned on, the table data and all associated indexes are stored in a **.ibd file** located inside the database directory. When this option is turned off, all **InnoDB** tables and indexes are stored in the **system tablespace**, represented by one or more **ibdata*** files.

For **MyISAM** tables, the storage engine creates data and index files. Thus, for each **MyISAM** table *tbl_name*, there are three disk files.

| File | Purpose |
|---------------------|--------------------------------|
| <i>tbl_name.frm</i> | Table format (definition) file |

| File | Purpose |
|---------------------------|------------|
| <code>tbl_name.MYD</code> | Data file |
| <code>tbl_name.MYI</code> | Index file |

Chapter 15, *Alternative Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

Limits Imposed by .frm File Structure

As described previously, each table has an `.frm` file that contains the table definition. The server uses the following expression to check some of the table information stored in the file against an upper limit of 64KB:

```
if (info_length+(ulong) create_fields.elements*FCOMP+288+
    n_length+int_length+com_length > 65535L || int_count > 255)
```

The portion of the information stored in the `.frm` file that is checked against the expression cannot grow beyond the 64KB limit, so if the table definition reaches this size, no more columns can be added.

The relevant factors in the expression are:

- `info_length` is space needed for “screens.” This is related to MySQL's Unireg heritage.
- `create_fields.elements` is the number of columns.
- `FCOMP` is 17.
- `n_length` is the total length of all column names, including one byte per name as a separator.
- `int_length` is related to the list of values for `ENUM` and `SET` columns. In this context, “int” does not mean “integer.” It means “interval,” a term that refers collectively to `ENUM` and `SET` columns.
- `int_count` is the number of unique `ENUM` and `SET` definitions.
- `com_length` is the total length of column comments.

The expression just described has several implications for permitted table definitions:

- Using long column names can reduce the maximum number of columns, as can the inclusion of `ENUM` or `SET` columns, or use of column comments.
- A table can have no more than 255 unique `ENUM` and `SET` definitions. Columns with identical element lists are considered the same against this limit. For example, if a table contains these two columns, they count as one (not two) toward this limit because the definitions are identical:

```
e1 ENUM('a','b','c')
e2 ENUM('a','b','c')
```

- The sum of the length of element names in the unique `ENUM` and `SET` definitions counts toward the 64KB limit, so although the theoretical limit on number of elements in a given `ENUM` column is 65,535, the practical limit is less than 3000.

13.1.17.3 CREATE TEMPORARY TABLE Statement

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.)

`CREATE TABLE` causes an implicit commit, except when used with the `TEMPORARY` keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`TEMPORARY` tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any `TEMPORARY` tables created within that database. Also, you can create a `TEMPORARY` table in a nonexistent database if you qualify the table name with the database name in the `CREATE TABLE` statement. In this case, all subsequent references to the table must be qualified with the database name.

To create a temporary table, you must have the `CREATE TEMPORARY TABLES` privilege. However, other operations on a temporary table, such as `INSERT`, `UPDATE`, or `SELECT`, require additional privileges for those operations for the database containing the temporary table, or for the nontemporary table of the same name.

To keep privileges for temporary and nontemporary tables separate, a common workaround for this situation is to create a database dedicated to the use of temporary tables. Then for that database, a user can be granted the `CREATE TEMPORARY TABLES` privilege, along with any other privileges required for temporary table operations done by that user.

13.1.17.4 CREATE TABLE ... LIKE Statement

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

Important

Beginning with MySQL 5.5.3, you cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

Also as of MySQL 5.5.3, `CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE` and does not just copy the `.frm` file. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

13.1.17.5 CREATE TABLE ... SELECT Statement

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (a), KEY(b))
-> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a [MyISAM](#) table with three columns, `a`, `b`, and `c`. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n |
+----+
| 1 |
+----+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
| m      | n |
+-----+-----+
| NULL  | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error.

Because the ordering of the rows in the underlying `SELECT` statements cannot always be determined, `CREATE TABLE ... IGNORE SELECT` and `CREATE TABLE ... REPLACE SELECT` statements in MySQL 5.5.18 and later are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. See also [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
  SELECT artist.name, COUNT(work.artist_id) AS number_of_works
```

```
FROM artist LEFT JOIN work ON artist.id = work.artist_id
GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the destination table already exists, the result is version dependent. Before MySQL 5.5.6, MySQL handles the statement as follows:

- The table definition given in the `CREATE TABLE` part is ignored. No error occurs, even if the definition does not match that of the existing table. MySQL attempts to insert the rows from the `SELECT` part anyway.
- If there is a mismatch between the number of columns in the table and the number of columns produced by the `SELECT` part, the selected values are assigned to the rightmost columns. For example, if the table contains n columns and the `SELECT` produces m columns, where $m < n$, the selected values are assigned to the m rightmost columns in the table. Each of the initial $n - m$ columns is assigned its default value, either that specified explicitly in the column definition or the implicit column data type default if the definition contains no default. If the `SELECT` part produces too many columns ($m > n$), an error occurs.
- If strict SQL mode is enabled and any of these initial columns do not have an explicit default value, the statement fails with an error.

The following example illustrates `IF NOT EXISTS` handling:

```
mysql> CREATE TABLE t1 (i1 INT DEFAULT 0, i2 INT, i3 INT, i4 INT);
Query OK, 0 rows affected (0.05 sec)

mysql> CREATE TABLE IF NOT EXISTS t1 (c1 CHAR(10)) SELECT 1, 2;
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+-----+-----+-----+-----+
| i1   | i2   | i3   | i4   |
+-----+-----+-----+-----+
| 0    | NULL | 1    | 2    |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

As of MySQL 5.5.6, handling of `CREATE TABLE IF NOT EXISTS ... SELECT` statements was changed for the case that the destination table already exists. This change also involves a change in MySQL 5.1 beginning with 5.1.51.

- Previously, for `CREATE TABLE IF NOT EXISTS ... SELECT`, MySQL produced a warning that the table exists, but inserted the rows and wrote the statement to the binary log anyway. By contrast, `CREATE TABLE ... SELECT` (without `IF NOT EXISTS`) failed with an error, but MySQL inserted no rows and did not write the statement to the binary log.
- MySQL now handles both statements the same way when the destination table exists, in that neither statement inserts rows or is written to the binary log. The difference between them is that MySQL produces a warning when `IF NOT EXISTS` is present and an error when it is not.

This change means that, for the preceding example, the `CREATE TABLE IF NOT EXISTS ... SELECT` statement inserts nothing into the destination table as of MySQL 5.5.6.

This change in handling of `IF NOT EXISTS` results in an incompatibility for statement-based replication from a MySQL 5.1 master with the original behavior and a MySQL 5.5 slave with the new behavior. Suppose that `CREATE TABLE IF NOT EXISTS ... SELECT` is executed on the master and the destination table exists. The result is that rows are inserted on the master but not on the slave. (Row-based replication does not have this problem.)

To address this issue, statement-based binary logging for `CREATE TABLE IF NOT EXISTS ... SELECT` is changed in MySQL 5.1 as of 5.1.51:

- If the destination table does not exist, there is no change: The statement is logged as is.
- If the destination table does exist, the statement is logged as the equivalent pair of `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements. (If the `SELECT` in the original statement is preceded by `IGNORE` or `REPLACE`, the `INSERT` becomes `INSERT IGNORE` or `REPLACE`, respectively.)

This change provides forward compatibility for statement-based replication from MySQL 5.1 to 5.5 because when the destination table exists, the rows will be inserted on both the master and slave. To take advantage of this compatibility measure, the 5.1 server must be at least 5.1.51 and the 5.5 server must be at least 5.5.6.

To upgrade an existing 5.1-to-5.5 replication scenario, upgrade the master first to 5.1.51 or higher. Note that this differs from the usual replication upgrade advice of upgrading the slave first.

A workaround for applications that wish to achieve the original effect (rows inserted regardless of whether the destination table exists) is to use `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements rather than `CREATE TABLE IF NOT EXISTS ... SELECT` statements.

Along with the change just described, the following related change was made: Previously, if an existing view was named as the destination table for `CREATE TABLE IF NOT EXISTS ... SELECT`, rows were inserted into the underlying base table and the statement was written to the binary log. As of MySQL 5.1.51 and 5.5.6, nothing is inserted or logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

13.1.17.6 FOREIGN KEY Constraints

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.

A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.

The essential syntax for a defining a foreign key constraint in a `CREATE TABLE` or `ALTER TABLE` statement includes the following:

```
[CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (col_name, ...)
  REFERENCES tbl_name (col_name,...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

Foreign key constraint usage is described under the following topics in this section:

- [Identifiers](#)
- [Conditions and Restrictions](#)
- [Referential Actions](#)
- [Foreign Key Constraint Examples](#)
- [Adding Foreign Key Constraints](#)

- [Dropping Foreign Key Constraints](#)
- [Foreign Key Checks](#)
- [Foreign Key Definitions and Metadata](#)
- [Foreign Key Errors](#)

Identifiers

Foreign key constraint naming is governed by the following rules:

- The `CONSTRAINT symbol` value is used, if defined.
- If the `CONSTRAINT symbol` clause is not defined, or a symbol is not included following the `CONSTRAINT` keyword, a constraint name is generated automatically.
- The `CONSTRAINT symbol` value, if defined, must be unique in the database. A duplicate `symbol` results in an error similar to: `ERROR 1005 (HY000): Can't create table 'test.fk1' (errno: 121)`.

Table and column identifiers in a `FOREIGN KEY ... REFERENCES` clause can be quoted within backticks (```). Alternatively, double quotation marks (`"`) can be used if the `ANSI_QUOTES` SQL mode is enabled. The `lower_case_table_names` system variable setting is also taken into account.

Conditions and Restrictions

Foreign key constraints are subject to the following conditions and restrictions:

- Parent and child tables must use the same storage engine, and they cannot be defined as temporary tables.
- Creating a foreign key constraint requires at least one of the `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `REFERENCES` privileges on the parent table as of 5.5.41.
- Corresponding columns in the foreign key and the referenced key must have similar data types. *The size and sign of integer types must be the same.* The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, a “child table record” refers to a dependent record within the same table.
- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later if you create another index that can be used to enforce the foreign key constraint. `index_name`, if given, is used as described previously.
- `InnoDB` permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are the *first* columns in the same order. Hidden columns that `InnoDB` adds to an index are also considered (see [Section 14.9.2.1, “Clustered and Secondary Indexes”](#)).

`InnoDB` does not require an explicit unique key (or primary key) on any column referenced as a foreign key, which is an extension of standard SQL.

- Index prefixes on foreign key columns are not supported. Consequently, `BLOB` and `TEXT` columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.

- [InnoDB](#) does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.
- A table in a foreign key relationship cannot be altered to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

For information about how the MySQL implementation of foreign key constraints differs from the SQL standard, see [Section 1.7.2.3, “FOREIGN KEY Constraint Differences”](#).

Referential Actions

When an [UPDATE](#) or [DELETE](#) operation affects a key value in the parent table that has matching rows in the child table, the result depends on the *referential action* specified by [ON UPDATE](#) and [ON DELETE](#) subclauses of the [FOREIGN KEY](#) clause. Referential actions include:

- [CASCADE](#): Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both [ON DELETE CASCADE](#) and [ON UPDATE CASCADE](#) are supported. Between two tables, do not define several [ON UPDATE CASCADE](#) clauses that act on the same column in the parent table or in the child table.

Note

Cascaded foreign key actions do not activate triggers.

- [SET NULL](#): Delete or update the row from the parent table and set the foreign key column or columns in the child table to [NULL](#). Both [ON DELETE SET NULL](#) and [ON UPDATE SET NULL](#) clauses are supported.

If you specify a [SET NULL](#) action, *make sure that you have not declared the columns in the child table as [NOT NULL](#)*.

- [RESTRICT](#): Rejects the delete or update operation for the parent table. Specifying [RESTRICT](#) (or [NO ACTION](#)) is the same as omitting the [ON DELETE](#) or [ON UPDATE](#) clause.
- [NO ACTION](#): A keyword from standard SQL. In MySQL, equivalent to [RESTRICT](#). The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and [NO ACTION](#) is a deferred check. In MySQL, foreign key constraints are checked immediately, so [NO ACTION](#) is the same as [RESTRICT](#).
- [SET DEFAULT](#): This action is recognized by the MySQL parser, but [InnoDB](#) rejects table definitions containing [ON DELETE SET DEFAULT](#) or [ON UPDATE SET DEFAULT](#) clauses.

For storage engines that support foreign keys, MySQL rejects any [INSERT](#) or [UPDATE](#) operation that attempts to create a foreign key value in a child table if there is no matching candidate key value in the parent table.

For an [ON DELETE](#) or [ON UPDATE](#) that is not specified, the default action is always [RESTRICT](#).

[InnoDB](#) performs cascading operations using a depth-first search algorithm on the records of the index that corresponds to the foreign key constraint.

Foreign Key Constraint Examples

This simple example relates [parent](#) and [child](#) tables through a single-column foreign key:

```
CREATE TABLE parent (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE child (
```

```

id INT,
parent_id INT,
INDEX par_ind (parent_id),
FOREIGN KEY (parent_id)
    REFERENCES parent(id)
    ON DELETE CASCADE
) ENGINE=INNODB;

```

This is a more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```

CREATE TABLE product (
    category INT NOT NULL, id INT NOT NULL,
    price DECIMAL,
    PRIMARY KEY(category, id)
) ENGINE=INNODB;

CREATE TABLE customer (
    id INT NOT NULL,
    PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE product_order (
    no INT NOT NULL AUTO_INCREMENT,
    product_category INT NOT NULL,
    product_id INT NOT NULL,
    customer_id INT NOT NULL,

    PRIMARY KEY(no),
    INDEX (product_category, product_id),
    INDEX (customer_id),

    FOREIGN KEY (product_category, product_id)
        REFERENCES product(category, id)
        ON UPDATE CASCADE ON DELETE RESTRICT,

    FOREIGN KEY (customer_id)
        REFERENCES customer(id)
) ENGINE=INNODB;

```

Adding Foreign Key Constraints

You can add a foreign key constraint to an existing table using the following `ALTER TABLE` syntax:

```

ALTER TABLE tbl_name
    ADD [CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (col_name, ...)
    REFERENCES tbl_name (col_name,...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, *remember to first create an index on the column(s) referenced by the foreign key.*

Dropping Foreign Key Constraints

You can drop a foreign key constraint using the following `ALTER TABLE` syntax:

```

ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;

```

If the `FOREIGN KEY` clause defined a `CONSTRAINT` name when you created the constraint, you can refer to that name to drop the foreign key constraint. Otherwise, a constraint name was generated internally, and you must use that value. To determine the foreign key constraint name, use `SHOW CREATE TABLE`:

```

mysql> SHOW CREATE TABLE child\G

```

```

***** 1. row *****
      Table: child
Create Table: CREATE TABLE `child` (
  `id` int(11) DEFAULT NULL,
  `parent_id` int(11) DEFAULT NULL,
  KEY `par_ind` (`parent_id`),
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
  REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=latin1

mysql> ALTER TABLE child DROP FOREIGN KEY `child_ibfk_1`;

```

Adding and dropping a foreign key in separate clauses of a single `ALTER TABLE` statement may be problematic in some cases and is therefore unsupported. Use separate statements for each operation.

If an `ALTER TABLE` statement results in changes to column values (for example, because a column is truncated), MySQL's foreign key constraint checks do not notice possible violations caused by changing the values.

Foreign Key Checks

Foreign key checking is controlled by the `foreign_key_checks` variable, which is enabled by default. Typically, you leave this variable enabled during normal operation to enforce referential integrity.

The `foreign_key_checks` variable is dynamic and supports both global and session scopes. For information about using system variables, see [Section 5.1.8, “Using System Variables”](#).

Disabling foreign key checking is useful when:

- Dropping a table that is referenced by a foreign key constraint. A referenced table can only be dropped after `foreign_key_checks` is disabled. When you drop a table, constraints defined on the table are also dropped.
- Reloading tables in different order than required by their foreign key relationships. For example, `mysqldump` produces correct definitions of tables in the dump file, including foreign key constraints for child tables. To make it easier to reload dump files for tables with foreign key relationships, `mysqldump` automatically includes a statement in the dump output that disables `foreign_key_checks`. This enables you to import the tables in any order in case the dump file contains tables that are not correctly ordered for foreign keys. Disabling `foreign_key_checks` also speeds up the import operation by avoiding foreign key checks.
- Executing `LOAD DATA` operations, to avoid foreign key checking.
- Performing an `ALTER TABLE` operation on a table that has a foreign key relationship.

When `foreign_key_checks` is disabled, foreign key constraints are ignored, with the following exceptions:

- Recreating a table that was previously dropped returns an error if the table definition does not conform to the foreign key constraints that reference the table. The table must have the correct column names and types. It must also have indexes on the referenced keys. If these requirements are not satisfied, MySQL returns Error 1005 that refers to errno: 150 in the error message, which means that a foreign key constraint was not correctly formed.
- Altering a table returns an error (errno: 150) if a foreign key definition is incorrectly formed for the altered table.
- Dropping an index required by a foreign key constraint. The foreign key constraint must be removed before dropping the index.
- Creating a foreign key constraint where a column references a nonmatching column type.

Disabling `foreign_key_checks` has these additional implications:

- It is permitted to drop a database that contains tables with foreign keys that are referenced by tables outside the database.
- It is permitted to drop a table with foreign keys referenced by other tables.
- Enabling `foreign_key_checks` does not trigger a scan of table data, which means that rows added to a table while `foreign_key_checks` is disabled are not checked for consistency when `foreign_key_checks` is re-enabled.

Foreign Key Definitions and Metadata

To view a foreign key definition, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE child\G
***** 1. row *****
      Table: child
Create Table: CREATE TABLE `child` (
  `id` int(11) DEFAULT NULL,
  `parent_id` int(11) DEFAULT NULL,
  KEY `par_ind` (`parent_id`),
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
  REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

You can obtain information about foreign keys from the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
        FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
        WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
+-----+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | COLUMN_NAME | CONSTRAINT_NAME |
+-----+-----+-----+-----+
| test         | child       | parent_id   | child_ibfk_1    |
+-----+-----+-----+-----+
```

Foreign Key Errors

In the event of a foreign key error involving `InnoDB` tables (usually Error 150 in the MySQL Server), information about the latest foreign key error can be obtained by checking `SHOW ENGINE INNODB STATUS` output.

```
mysql> SHOW ENGINE INNODB STATUS\G
...
-----
LATEST FOREIGN KEY ERROR
-----
141016 15:37:30 Transaction:
TRANSACTION 3D005, ACTIVE 0 sec inserting
mysql tables in use 1, locked 1

Foreign key constraint fails for table `mysql`.`child`:
'
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) REFERENCES `parent` (`id`)
  ON DELETE CASCADE ON UPDATE CASCADE
Trying to add in child table, in index `par_ind` tuple:
DATA TUPLE: 2 fields;
```

```

0: len 4; hex 80000003; asc    ;;
1: len 4; hex 80000003; asc    ;;

But in parent table `mysql`.`parent`, in index `PRIMARY`,
the closest match we can find is record:
PHYSICAL RECORD: n_fields 3; compact format; info bits 0
0: len 4; hex 80000004; asc    ;;
1: len 6; hex 00000003d002; asc    ;;
2: len 7; hex 8300001d480137; asc    H 7;;
...

```

Warning

[ER_NO_REFERENCED_ROW_2](#) and [ER_ROW_IS_REFERENCED_2](#) error messages for foreign key operations expose information about parent tables, even if the user has no parent table access privileges. To hide information about parent tables, include the appropriate condition handlers in application code and stored programs.

13.1.17.7 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

- [TIMESTAMP](#) display sizes are discarded.

Also note that [TIMESTAMP](#) columns are [NOT NULL](#) by default.

- Columns that are part of a [PRIMARY KEY](#) are made [NOT NULL](#) even if not declared that way.
- Trailing spaces are automatically deleted from [ENUM](#) and [SET](#) member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See [Section 11.8, “Using Data Types from Other Database Engines”](#).
- If you include a [USING](#) clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a [VARCHAR](#) column with a length specification greater than 65535 is converted to [TEXT](#), and a [VARBINARY](#) column with a length specification greater than 65535 is converted to [BLOB](#). Otherwise, an error occurs in either of these cases.
- Specifying the [CHARACTER SET binary](#) attribute for a character data type causes the column to be created as the corresponding binary data type: [CHAR](#) becomes [BINARY](#), [VARCHAR](#) becomes [VARBINARY](#), and [TEXT](#) becomes [BLOB](#). For the [ENUM](#) and [SET](#) data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```

CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);

```

The resulting table has this definition:

```

CREATE TABLE t
(
  c1 VARBINARY(10),

```

```
c2 BLOB,
c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a [DESCRIBE](#) or [SHOW CREATE TABLE](#) statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using [myisampack](#). See [Section 15.3.3.3, “Compressed Table Characteristics”](#).

13.1.18 CREATE TABLESPACE Statement

```
CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
  USE LOGFILE GROUP logfile_group
  [EXTENT_SIZE [=] extent_size]
  [INITIAL_SIZE [=] initial_size]
  [AUTOEXTEND_SIZE [=] autoextend_size]
  [MAX_SIZE [=] max_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] comment_text]
  ENGINE [=] engine_name
```

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for tables. One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the [ALTER TABLESPACE](#) statement (see [Section 13.1.8, “ALTER TABLESPACE Statement”](#)). For rules covering the naming of tablespaces, see [Section 9.2, “Schema Object Names”](#).

Note

All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more [UNDO](#) log files must be assigned to the tablespace to be created with the [USE LOGFILE GROUP](#) clause. *logfile_group* must be an existing log file group created with [CREATE LOGFILE GROUP](#) (see [Section 13.1.14, “CREATE LOGFILE GROUP Statement”](#)). Multiple tablespaces may use the same log file group for [UNDO](#) logging.

The [EXTENT_SIZE](#) sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

An *extent* is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may be used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data from more than one partition. This means, for example, that a tablespace having a single datafile whose [INITIAL_SIZE](#) is 256 MB and whose [EXTENT_SIZE](#) is 128M has just two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the [INFORMATION_SCHEMA.FILES](#) table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see [Section 21.30.1, “The INFORMATION_SCHEMA FILES Table”](#).

The `INITIAL_SIZE` parameter sets the data file's total size in bytes. Once the file has been created, its size cannot be changed; however, you can add more data files to the tablespace using `ALTER TABLESPACE ... ADD DATAFILE`. See [Section 13.1.8, “ALTER TABLESPACE Statement”](#).

`INITIAL_SIZE` is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

When setting `EXTENT_SIZE`, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes). In MySQL NDB Cluster 7.2.14 and later, these abbreviations are also supported when specifying `INITIAL_SIZE` as well. (Bug #13116514, Bug #16104705, Bug #62858)

`INITIAL_SIZE`, `EXTENT_SIZE`, and `UNDO_BUFFER_SIZE` are subject to rounding as follows:

- `EXTENT_SIZE` and `UNDO_BUFFER_SIZE` are each rounded up to the nearest whole multiple of 32K.
- `INITIAL_SIZE` is rounded *down* to the nearest whole multiple of 32K.

For data files, `INITIAL_SIZE` is subject to further rounding; the result just obtained is rounded up to the nearest whole multiple of `EXTENT_SIZE` (after any rounding).

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating `INFORMATION_SCHEMA.FILES` column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

`AUTOEXTEND_SIZE`, `MAX_SIZE`, `NODEGROUP`, `WAIT`, and `COMMENT` are parsed but ignored, and so currently have no effect. These options are intended for future expansion.

The `ENGINE` parameter determines the storage engine which uses this tablespace, with `engine_name` being the name of the storage engine. Currently, `engine_name` must be one of the values `NDB` or `NDBCLUSTER`.

When `CREATE TABLESPACE` is used with `ENGINE = NDB`, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
  -> FROM INFORMATION_SCHEMA.FILES
  -> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
+-----+-----+-----+
| LOGFILE_GROUP_NAME | FILE_NAME | EXTRA |
+-----+-----+-----+
| lg_3               | newdata.dat | CLUSTER_NODE=3 |
| lg_3               | newdata.dat | CLUSTER_NODE=4 |
+-----+-----+-----+
2 rows in set (0.01 sec)
```

(See [Section 21.30.1, “The INFORMATION_SCHEMA FILES Table”](#).)

`CREATE TABLESPACE` is useful only with Disk Data storage for NDB Cluster. See [Section 18.5.12, “NDB Cluster Disk Data Tables”](#).

13.1.19 CREATE TRIGGER Statement

```
CREATE
  [DEFINER = user]
  TRIGGER trigger_name
  trigger_time trigger_event
  ON tbl_name FOR EACH ROW
  trigger_body

trigger_time: { BEFORE | AFTER }
```

```
trigger_event: { INSERT | UPDATE | DELETE }
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named *tbl_name*, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes `CREATE TRIGGER` syntax. For additional discussion, see [Section 20.3.1, “Trigger Syntax and Examples”](#).

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. If the `DEFINER` clause is present, the privileges required depend on the *user* value, as discussed in [Section 20.6, “Stored Object Access Control”](#). If binary logging is enabled, `CREATE TRIGGER` might require the `SUPER` privilege, as discussed in [Section 20.7, “Stored Program Binary Logging”](#).

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

trigger_time is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use `BEFORE` triggers to convert values inappropriate for the column type to valid values.

trigger_event indicates the kind of operation that activates the trigger. These *trigger_event* values are permitted:

- `INSERT`: The trigger activates whenever a new row is inserted into the table (for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements).
- `UPDATE`: The trigger activates whenever a row is modified (for example, through `UPDATE` statements).
- `DELETE`: The trigger activates whenever a row is deleted from the table (for example, through `DELETE` and `REPLACE` statements). `DROP TABLE` and `TRUNCATE TABLE` statements on the table do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

The *trigger_event* does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger activates not only for `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

Note

Cascaded foreign key actions do not activate triggers.

There cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

trigger_body is the statement to execute when the trigger activates. To execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use

the same statements that are permissible within stored routines. See [Section 13.6.1, “BEGIN ... END Compound Statement”](#). Some statements are not permitted in triggers; see [Section 20.8, “Restrictions on Stored Programs”](#).

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

MySQL stores the `sql_mode` system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, *regardless of the current server SQL mode when the trigger begins executing*.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in [Section 20.6, “Stored Object Access Control”](#). Also see that section for additional information about trigger security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
 - The `TRIGGER` privilege for the subject table.
 - The `SELECT` privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.
 - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.
 - Whatever other privileges normally are required for the statements executed by the trigger.

Within a trigger body, the `CURRENT_USER` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see [Section 6.2.14, “SQL-Based Account Activity Auditing”](#).

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in [LOCK TABLES and Triggers](#).

For additional discussion of trigger use, see [Section 20.3.1, “Trigger Syntax and Examples”](#).

13.1.20 CREATE VIEW Statement

```
CREATE
  [OR REPLACE]
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = user]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` replaces it.

For information about restrictions on view use, see [Section 20.9, “Restrictions on Views”](#).

The *select_statement* is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The *select_statement* can select from base tables or other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table will result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. If the `DEFINER` clause is present, the privileges required depend on the *user* value, as discussed in [Section 20.6, “Stored Object Access Control”](#).

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use *db_name.view_name* syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional *column_list* clause as a list of comma-separated identifiers. The number of names in *column_list* must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty  | price | value |
+-----+-----+-----+
| 3    | 50    | 150   |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY` or filtering or grouping. When `ORDER BY` is combined with `LIMIT` or `OFFSET` in a view definition, the ordering is always enforced before the query result is used by the outer query, but it does not guarantee that the same ordering is used in the end result. As a workaround, add an `ORDER BY` clause to the outer query.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc   |
+-----+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL`

`SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in [Section 20.6, “Stored Object Access Control”](#). Also see that section for additional information about view security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within a view definition, the `CURRENT_USER` function returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view's invoker. For information about user auditing within views, see [Section 6.2.14, “SQL-Based Account Activity Auditing”](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT` privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.
- The user who references a view must have appropriate privileges to access it (`SELECT` to select from it, `INSERT` to insert into it, and so forth.)
- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view `DEFINER` account or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of the `DEFINER` account. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY DEFINER`. The standard says that the

definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, [SELECT](#)) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The [DEFINER](#) clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default [DEFINER](#) value is the account of the view creator.

The optional [ALGORITHM](#) clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. [ALGORITHM](#) takes three values: [MERGE](#), [TEMPTABLE](#), or [UNDEFINED](#). The default algorithm is [UNDEFINED](#) if no [ALGORITHM](#) clause is present. For more information, see [Section 20.5.2, “View Processing Algorithms”](#), as well as [Optimizing Derived Tables](#).

Some views are updatable. That is, you can use them in statements such as [UPDATE](#), [DELETE](#), or [INSERT](#) to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

The [WITH CHECK OPTION](#) clause can be given for an updatable view to prevent inserts or updates to rows except those for which the [WHERE](#) clause in the *select_statement* is true.

In a [WITH CHECK OPTION](#) clause for an updatable view, the [LOCAL](#) and [CASCADED](#) keywords determine the scope of check testing when the view is defined in terms of another view. The [LOCAL](#) keyword restricts the [CHECK OPTION](#) only to the view being defined. [CASCADED](#) causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is [CASCADED](#).

For more information about updatable views and the [WITH CHECK OPTION](#) clause, see [Section 20.5.3, “Updatable and Insertable Views”](#), and [Section 20.5.4, “The View WITH CHECK OPTION Clause”](#).

13.1.21 DROP DATABASE Statement

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

[DROP DATABASE](#) drops all tables in the database and deletes the database. Be very careful with this statement! To use [DROP DATABASE](#), you need the [DROP](#) privilege on the database. [DROP SCHEMA](#) is a synonym for [DROP DATABASE](#).

Important

When a database is dropped, privileges granted specifically for the database are *not* automatically dropped. They must be dropped manually. See [Section 13.7.1.3, “GRANT Statement”](#).

[IF EXISTS](#) is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the [DATABASE\(\)](#) function returns [NULL](#)).

If you use [DROP DATABASE](#) on a symbolically linked database, both the link and the original database are deleted.

[DROP DATABASE](#) returns the number of tables that were removed. This corresponds to the number of [.frm](#) files removed.

The [DROP DATABASE](#) statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions:
 - [.frm](#)
 - [.BAK](#)

- `.DAT`
- `.HSH`
- `.MRG`
- `.MYD`
- `.MYI`
- `.TRG`
- `.TRN`
- `.db`
- `.ibd`
- `.ndb`
- `.par`
- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See [Section 13.1.17.3, “CREATE TEMPORARY TABLE Statement”](#).

You can also drop databases with `mysqladmin`. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

13.1.22 DROP EVENT Statement

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named *event_name*. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

13.1.23 DROP FUNCTION Statement

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see [Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Statements”](#).
- For information about dropping user-defined functions, see [Section 13.7.3.2, “DROP FUNCTION Statement”](#).

13.1.24 DROP INDEX Statement

```
DROP [ONLINE|OFFLINE] INDEX index_name ON tbl_name
```

`DROP INDEX` drops the index named *index_name* from the table *tbl_name*. This statement is mapped to an `ALTER TABLE` statement to drop the index. See [Section 13.1.7, “ALTER TABLE Statement”](#).

To drop a primary key, the index name is always `PRIMARY`, which must be specified as a quoted identifier because `PRIMARY` is a reserved word:

```
DROP INDEX `PRIMARY` ON t;
```

Indexes on variable-width columns of NDB tables are dropped online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the *same* API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In standard MySQL 5.5 releases, it is not possible to override the server when it determines that an index is to be dropped without table copying. In NDB Cluster, you can drop indexes offline (which causes the table to be locked for all API nodes in the cluster) using the `OFFLINE` keyword. The rules and limitations governing `DROP OFFLINE INDEX` and `DROP ONLINE INDEX` are the same as for `ALTER OFFLINE TABLE ... DROP INDEX` and `ALTER ONLINE TABLE ... DROP INDEX`. You cannot cause the noncopying dropping of an index that would normally be dropped offline by using the `ONLINE` keyword: If it is not possible to perform the `DROP` operation without table copying, the server ignores the `ONLINE` keyword. For more information, see [Section 18.5.13, “Online Operations with ALTER TABLE in NDB Cluster”](#).

The `ONLINE` and `OFFLINE` keywords are available only in NDB Cluster; attempting to use these keywords in standard MySQL Server 5.5 releases results in a syntax error.

13.1.25 DROP LOGFILE GROUP Statement

```
DROP LOGFILE GROUP logfile_group
ENGINE [=] engine_name
```

This statement drops the log file group named *logfile_group*. The log file group must already exist or an error results. (For information on creating log file groups, see [Section 13.1.14, “CREATE LOGFILE GROUP Statement”](#).)

Important

Before dropping a log file group, you must drop all tablespaces that use that log file group for `UNDO` logging.

The required `ENGINE` clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for *engine_name* are `NDB` and `NDBCLUSTER`.

`DROP LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. See [Section 18.5.12, “NDB Cluster Disk Data Tables”](#).

13.1.26 DROP PROCEDURE and DROP FUNCTION Statements

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the `ALTER ROUTINE` privilege for the routine. (If the `automatic_sp_privileges` system variable is enabled, that privilege and `EXECUTE` are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See [Section 20.2.2, “Stored Routines and MySQL Privileges”](#).)

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

`DROP FUNCTION` is also used to drop user-defined functions (see [Section 13.7.3.2, “DROP FUNCTION Statement”](#)).

13.1.27 DROP SERVER Statement

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named *server_name*. The corresponding row in the `mysql.servers` table is deleted. This statement requires the `SUPER` privilege.

Dropping a server for a table does not affect any `FEDERATED` tables that used this connection information when they were created. See [Section 13.1.16, “CREATE SERVER Statement”](#).

`DROP SERVER` causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`DROP SERVER` is not written to the binary log, regardless of the logging format that is in use.

13.1.28 DROP TABLE Statement

```
DROP [TEMPORARY] TABLE [IF EXISTS]
    tbl_name [, tbl_name] ...
    [RESTRICT | CASCADE]
```

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table.

Be careful with this statement! For each table, it removes the table definition and all table data. If the table is partitioned, the statement removes the table definition, all its partitions, all data stored in those partitions, and all partition definitions associated with the dropped table.

Dropping a table also drops any triggers for the table.

`DROP TABLE` causes an implicit commit, except when used with the `TEMPORARY` keyword. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

Important

When a table is dropped, privileges granted specifically for the table are *not* automatically dropped. They must be dropped manually. See [Section 13.7.1.3, “GRANT Statement”](#).

If any tables named in the argument list do not exist, `DROP TABLE` behavior depends on whether the `IF EXISTS` clause is given:

- Without `IF EXISTS`, the statement drops all named tables that do exist, and returns an error indicating which nonexisting tables it was unable to drop.
- With `IF EXISTS`, no error occurs for nonexisting tables. The statement drops all named tables that do exist, and generates a `NOTE` diagnostic for each nonexistant table. These notes can be displayed with `SHOW WARNINGS`. See [Section 13.7.5.41, “SHOW WARNINGS Statement”](#).

`IF EXISTS` can also be useful for dropping tables in unusual circumstances under which there is an `.frm` file but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before `.frm` file removal.)

The `TEMPORARY` keyword has the following effects:

- The statement drops only `TEMPORARY` tables.
- The statement does not cause an implicit commit.
- No access rights are checked. A `TEMPORARY` table is visible only with the session that created it, so no check is necessary.

Including the `TEMPORARY` keyword is a good way to prevent accidentally dropping non-`TEMPORARY` tables.

The `RESTRICT` and `CASCADE` keywords do nothing. They are permitted to make porting easier from other database systems.

13.1.29 DROP TABLESPACE Statement

```
DROP TABLESPACE tablespace_name
ENGINE [=] engine_name
```

This statement drops a tablespace that was previously created using `CREATE TABLESPACE` (see [Section 13.1.18, “CREATE TABLESPACE Statement”](#)).

Important

The tablespace to be dropped must not contain any data files; in other words, before you can drop a tablespace, you must first drop each of its data files using `ALTER TABLESPACE ... DROP DATAFILE` (see [Section 13.1.8, “ALTER TABLESPACE Statement”](#)).

The `ENGINE` clause (required) specifies the storage engine used by the tablespace. Currently, the only accepted values for `engine_name` are `NDB` and `NDBCLUSTER`.

`DROP TABLESPACE` is useful only with Disk Data storage for NDB Cluster. See [Section 18.5.12, “NDB Cluster Disk Data Tables”](#).

13.1.30 DROP TRIGGER Statement

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a nonexistent trigger when using `IF EXISTS`. See [Section 13.7.5.41, “SHOW WARNINGS Statement”](#).

Triggers for a table are also dropped if you drop the table.

Note

When upgrading from a version of MySQL older than MySQL 5.0.10 to 5.0.10 or higher—including all MySQL 5.5 releases—you must drop all triggers and re-create them. Otherwise, `DROP TRIGGER` does not work for older triggers after the upgrade. See [Section 2.11.3, “Changes in MySQL 5.5”](#), for a suggested upgrade procedure.

13.1.31 DROP VIEW Statement

```
DROP VIEW [IF EXISTS]
view_name [, view_name] ...
[RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view.

If any views named in the argument list do not exist, the statement returns an error indicating by name which nonexistent views it was unable to drop, but also drops all views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each nonexistent view. See [Section 13.7.5.41, “SHOW WARNINGS Statement”](#).

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

13.1.32 RENAME TABLE Statement

```
RENAME TABLE
    tbl_name TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```

`RENAME TABLE` renames one or more tables. You must have `ALTER` and `DROP` privileges for the original table, and `CREATE` and `INSERT` privileges for the new table.

For example, to rename a table named `old_table` to `new_table`, use this statement:

```
RENAME TABLE old_table TO new_table;
```

That statement is equivalent to the following `ALTER TABLE` statement:

```
ALTER TABLE old_table RENAME new_table;
```

`RENAME TABLE`, unlike `ALTER TABLE`, can rename multiple tables within a single statement:

```
RENAME TABLE old_table1 TO new_table1,
              old_table2 TO new_table2,
              old_table3 TO new_table3;
```

Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
              new_table TO old_table,
              tmp_table TO new_table;
```

Metadata locks on tables are acquired in name order, which in some cases can make a difference in operation outcome when multiple transactions execute concurrently. See [Section 8.11.4, “Metadata Locking”](#).

To execute `RENAME TABLE`, there must be no active transactions or tables locked with `LOCK TABLES`. With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a `RENAME TABLE`, the statement fails and no changes are made.

You can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like `RENAME TABLE`, `ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a `Trigger in wrong schema (ER_TRG_IN_WRONG_SCHEMA)` error.

To rename `TEMPORARY` tables, `RENAME TABLE` does not work. Use `ALTER TABLE` instead.

`RENAME TABLE` works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.

`RENAME TABLE tbl_name TO new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string “`tbl_name_ibfk_`” to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string “`tbl_name_ibfk_`” as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

13.1.33 TRUNCATE TABLE Statement

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege.

Logically, `TRUNCATE TABLE` is similar to a `DELETE` statement that deletes all rows, or a sequence of `DROP TABLE` and `CREATE TABLE` statements. To achieve high performance, it bypasses the DML method of deleting data. Thus, it cannot be rolled back, it does not cause `ON DELETE` triggers to fire, and it cannot be performed for InnoDB tables with parent-child foreign key relationships.

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).
- Truncation operations cannot be performed if the session holds an active table lock.
- `TRUNCATE TABLE` fails for an InnoDB table if there are any `FOREIGN KEY` constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (`.par`) file is unaffected.
- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using InnoDB and other transactional storage engines where the transaction isolation level does not permit statement-based logging (`READ COMMITTED` or `READ UNCOMMITTED`), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replication slaves using InnoDB in the manner described previously.

On a system with a large InnoDB buffer pool and `innodb_adaptive_hash_index` enabled, `TRUNCATE TABLE` operations may cause a temporary drop in system performance due to an LRU

scan that occurs when removing an [InnoDB](#) table's adaptive hash index entries. The problem was addressed for [DROP TABLE](#) in MySQL 5.5.23 (Bug #13704145, Bug #64284) but remains a known issue for [TRUNCATE TABLE](#) (Bug #68184).

[TRUNCATE TABLE](#) can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or [NULL](#), not to remove rows. See [Section 22.10.5, "Performance Schema Summary Tables"](#).

13.2 Data Manipulation Statements

13.2.1 CALL Statement

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

The [CALL](#) statement invokes a stored procedure that was defined previously with [CREATE PROCEDURE](#).

Stored procedures that take no arguments can be invoked without parentheses. That is, [CALL p\(\)](#) and [CALL p](#) are equivalent.

[CALL](#) can pass back values to its caller using parameters that are declared as [OUT](#) or [INOUT](#) parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the [ROW_COUNT\(\)](#) function; from the C API, call the [mysql_affected_rows\(\)](#) function.

For information about the effect of unhandled conditions on procedure parameters, see [Section 13.6.7.5, "Condition Handling and OUT or INOUT Parameters"](#).

To get back a value from a procedure using an [OUT](#) or [INOUT](#) parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an [IN](#) or [INOUT](#) parameter.) For an [INOUT](#) parameter, initialize its value before passing it to the procedure. The following procedure has an [OUT](#) parameter that the procedure sets to the current server version, and an [INOUT](#) value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the [INOUT](#) parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version          | @increment |
+-----+-----+
| 5.5.58-debug-log |          11 |
+-----+-----+
```

In prepared [CALL](#) statements used with [PREPARE](#) and [EXECUTE](#), placeholders can be used for [IN](#) parameters, [OUT](#), and [INOUT](#) parameters. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
```

```

+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.58-debug-log | 11 |
+-----+-----+

```

To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). `CLIENT_MULTI_RESULTS` is enabled by default.

To process the result of a `CALL` statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 23.7.15, “C API Multiple Statement Execution Support”](#).

C programs can use the prepared-statement interface to execute `CALL` statements and access `OUT` and `INOUT` parameters. This is done by processing the result of a `CALL` statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see [Section 23.7.17, “C API Prepared CALL Statement Support”](#). Languages that provide a MySQL interface can use prepared `CALL` statements to directly retrieve `OUT` and `INOUT` procedure parameters.

13.2.2 DELETE Statement

`DELETE` is a DML statement that removes rows from a table.

Single-table syntax:

```

DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]

```

Multiple-table syntax:

```

DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    tbl_name [, tbl_name [...]] ...
    FROM table_references
    [WHERE where_condition]

DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    FROM tbl_name [, tbl_name [...]] ...
    USING table_references
    [WHERE where_condition]

```

For the single-table syntax, the `DELETE` statement deletes rows from `tbl_name` and returns a count of the number of deleted rows. This count can be obtained by calling the `ROW_COUNT()` function (see [Section 12.15, “Information Functions”](#)). The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, `DELETE` deletes from each `tbl_name` the rows that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` cannot be used.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 13.2.9, “SELECT Statement”](#).

You cannot delete from a table and select from the same table in a subquery.

You need the `DELETE` privilege on a table to delete rows from it. You need only the `SELECT` privilege for any columns that are only read, such as those named in the `WHERE` clause.

As stated, a `DELETE` statement with no `WHERE` clause deletes all rows. A faster way to do this, when you do not need to know the number of deleted rows, is to use `TRUNCATE TABLE`. However, within a transaction or if you have a lock on the table, `TRUNCATE TABLE` cannot be used whereas `DELETE` can. See [Section 13.1.33, “TRUNCATE TABLE Statement”](#), and [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Statements”](#).

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `autocommit` mode, the sequence starts over for all storage engines except `InnoDB` and `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, as discussed in [Section 14.9.1.4, “AUTO_INCREMENT Handling in InnoDB”](#).

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

The `DELETE` statement supports the following modifiers:

- If you specify the `LOW_PRIORITY` modifier, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- For `MyISAM` tables, if you use the `QUICK` modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The `IGNORE` modifier causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings.

The speed of delete operations may also be affected by factors discussed in [Section 8.2.4.3, “Optimizing DELETE Statements”](#).

In `MyISAM` tables, deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. To reclaim unused space and reduce file sizes, use the `OPTIMIZE TABLE` statement or the `myisamchk` utility to reorganize tables. `OPTIMIZE TABLE` is easier to use, but `myisamchk` is faster. See [Section 13.7.2.4, “OPTIMIZE TABLE Statement”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

The `QUICK` modifier affects whether index leaves are merged for delete operations. `DELETE QUICK` is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

`DELETE QUICK` is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of `QUICK` can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed `AUTO_INCREMENT` column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using `DELETE QUICK`.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of `QUICK`. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they

remain underfilled even if you later use `DELETE` without `QUICK`, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use `OPTIMIZE TABLE`.

If you are going to delete many rows from a table, it might be faster to use `DELETE QUICK` followed by `OPTIMIZE TABLE`. This rebuilds the index rather than performing many index block merge operations.

The MySQL-specific `LIMIT row_count` option to `DELETE` tells the server the maximum number of rows to be deleted before control is returned to the client. This can be used to ensure that a given `DELETE` statement does not take too much time. You can simply repeat the `DELETE` statement until the number of affected rows is less than the `LIMIT` value.

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

`ORDER BY` may also be useful in some cases to delete rows in an order required to avoid referential integrity violations.

If you are deleting many rows from a large table, you may exceed the lock table size for an `InnoDB` table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use `DELETE` at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use `RENAME TABLE` to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while `RENAME TABLE` executes, so the rename operation is not subject to concurrency problems. See [Section 13.1.32, “RENAME TABLE Statement”](#).

You can specify multiple tables in a `DELETE` statement to delete rows from one or more tables depending on the condition in the `WHERE` clause. You cannot use `ORDER BY` or `LIMIT` in a multiple-table `DELETE`. The `table_references` clause lists the tables involved in the join, as described in [Section 13.2.9.2, “JOIN Clause”](#).

For the first multiple-table syntax, only matching rows from the tables listed before the `FROM` clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the `FROM` clause (before the `USING` clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples use `INNER JOIN`, but multiple-table `DELETE` statements can use other types of join permitted in `SELECT` statements, such as `LEFT JOIN`. For example, to delete rows that exist in `t1` that have no match in `t2`, use a `LEFT JOIN`:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits `.*` after each `tbl_name` for compatibility with `Access`.

If you use a multiple-table `DELETE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly.

Note

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table `DELETE` should be declared only in the `table_references` part of the statement. Elsewhere, alias references are permitted but not alias declarations.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

```
DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

```
DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

13.2.3 DO Statement

```
DO expr [, expr] ...
```

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...`, but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

Example: This `SELECT` statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+-----+
| SLEEP(5) |
+-----+
|          0 |
+-----+
1 row in set (5.02 sec)
```

`DO`, on the other hand, pauses without producing a result set.:

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

`DO` only executes expressions. It cannot be used in all cases where `SELECT` can be used. For example, `DO id FROM t1` is invalid because it references a table.

13.2.4 HANDLER Statement

```
HANDLER tbl_name OPEN [ [AS] alias ]

HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
  [ WHERE where_condition ] [LIMIT ... ]

HANDLER tbl_name CLOSE
```

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for `InnoDB` and `MyISAM` tables.

The `HANDLER ... OPEN` statement opens a table, making it accessible using subsequent `HANDLER ... READ` statements. This table object is not shared by other sessions and is not closed until the session calls `HANDLER ... CLOSE` or the session terminates.

If you open the table using an alias, further references to the open table with other `HANDLER` statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier ``PRIMARY``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See [Section 13.2.9, “SELECT Statement”](#).

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:

- A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
- There is less parsing involved.
- There is no optimizer or query-checking overhead.
- The handler interface does not have to provide a consistent look of the data (for example, `dirty reads` are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.
- `HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface.
- `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does *not* take a snapshot of the table, and does *not* lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.
- The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

`HANDLER` is not supported with partitioned tables.

13.2.5 INSERT Statement

```

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [(col_name [, col_name] ...)]
  {VALUES | VALUE} (value_list) [, (value_list)] ...
  [ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  SET assignment_list
  [ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [(col_name [, col_name] ...)]
  SELECT ...
  [ON DUPLICATE KEY UPDATE assignment_list]

value:
  {expr | DEFAULT}

value_list:
  value [, value] ...

assignment:
  col_name = value
    
```

```
assignment_list:
  assignment [, assignment] ...
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT` with an `ON DUPLICATE KEY UPDATE` clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`.

For additional information about `INSERT ... SELECT` and `INSERT ... ON DUPLICATE KEY UPDATE`, see [Section 13.2.5.1, “INSERT ... SELECT Statement”](#), and [Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”](#).

Inserting into a table requires the `INSERT` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE` privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows replace the old rows rather than being discarded. See [Section 13.2.8, “REPLACE Statement”](#).

`tbl_name` is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the `VALUES` list or the `SELECT` statement.
- If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.
- A `SET` clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

- If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 11.5, “Data Type Default Values”](#). See also [Section 1.7.3.3, “Constraints on Invalid Data”](#).

If strict SQL mode is enabled, an `INSERT` statement generates an error if it does not specify an explicit value for every column that has no default value. See [Section 5.1.10, “Server SQL Modes”](#).

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the `VALUES` list.
- In expressions, you can use `DEFAULT(col_name)` to produce the default value for column `col_name`.

- Type conversion of an expression *expr* that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string '1999.0e-2' into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column inserts the value 1999, 19.9921, 19.992100, or 1999, respectively. The value stored in the `INT` and `YEAR` columns is 1999 because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the `FLOAT` and `DECIMAL` columns, the string-to-number conversion considers the entire string a valid numeric value.
- An expression *expr* can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

An exception occurs for columns that contain `AUTO_INCREMENT` values. Because `AUTO_INCREMENT` values are generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` SQL function or the `mysql_affected_rows()` C API function. See [Section 12.15, "Information Functions"](#), and [Section 23.7.6.1, "mysql_affected_rows\(\)"](#).

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: N1 Duplicates: N2 Warnings: N3
```

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See [Section 23.7.6.35, "mysql_info\(\)"](#).

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string (' ') for string types,

and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as `'10.34 a'` to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to `0`.
- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.
- For `INSERT` examples involving `AUTO_INCREMENT` column values, see [Section 3.6.9, “Using AUTO_INCREMENT”](#).

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function.

Note

These two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in [Section 12.15, “Information Functions”](#), and [Section 23.7.6.37, “mysql_insert_id\(\)”](#).

The `INSERT` statement supports the following modifiers:

- If you use the `DELAYED` modifier, the server puts the row or rows to be inserted into a buffer, and the client issuing the `INSERT DELAYED` statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See [Section 13.2.5.3, “INSERT DELAYED Statement”](#).

`DELAYED` is ignored with `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE`.

`DELAYED` is also disregarded for an `INSERT` that uses functions accessing tables or triggers, or that is called from a function or a trigger.

- If you use the `LOW_PRIORITY` modifier, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time (or even forever) in a read-heavy environment. (This is in contrast to `INSERT DELAYED`, which lets the client continue at once.)

`LOW_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

Note

`LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See [Section 8.11.3, “Concurrent Inserts”](#).

- If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See [Section 8.11.3, “Concurrent Inserts”](#).

`HIGH_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- If you use the `IGNORE` modifier, errors that occur while executing the `INSERT` statement are ignored. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row is discarded and no error occurs. Ignored errors may generate warnings instead, although duplicate-key errors do not.

`IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error. When `INSERT IGNORE` is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see [Section 19.2.2, “LIST Partitioning”](#).

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See [Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”](#).

An `INSERT` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. For more information, see [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

13.2.5.1 INSERT ... SELECT Statement

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [(col_name [, col_name] ...)]
  SELECT ...
  [ON DUPLICATE KEY UPDATE assignment_list]

value:
  {expr | DEFAULT}

assignment:
  col_name = value

assignment_list:
  assignment [, assignment] ...
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from the result of a `SELECT` statement, which can select from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.

- `DELAYED` is ignored with `INSERT ... SELECT`.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement. See [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#), and [Section B.4.6.2, “TEMPORARY Table Problems”](#).

- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements (see [Section 8.11.3, “Concurrent Inserts”](#)).
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

For `INSERT ... SELECT` statements, see [Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”](#) for conditions under which the `SELECT` columns can be referred to in an `ON DUPLICATE KEY UPDATE` clause.

The order in which a `SELECT` statement with no `ORDER BY` clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the master and the slave, which can lead to inconsistencies between them. To prevent this from occurring, always write `INSERT ... SELECT` statements that are to be replicated using an `ORDER BY` clause that produces the same row order on the master and the slave. See also [Section 17.4.1.16, “Replication and LIMIT”](#).

Due to this issue, beginning with MySQL 5.5.18, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

An `INSERT ... SELECT` statement affecting partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the source and target tables. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. For more information, see [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

13.2.5.2 INSERT ... ON DUPLICATE KEY UPDATE Statement

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE t1 SET c=c+1 WHERE a=1;
```

(The effects are not identical for an `InnoDB` table where `a` is an auto-increment column. With an auto-increment column, an `INSERT` statement increases the auto-increment value but `UPDATE` does not.)

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the `ON DUPLICATE KEY UPDATE` clause, you can use the `VALUES(col_name)` function to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause or `INSERT` statements and returns `NULL` otherwise. Example:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO t1 (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

For `INSERT ... SELECT` statements, these rules apply regarding acceptable forms of `SELECT` query expressions that you can refer to in an `ON DUPLICATE KEY UPDATE` clause:

- References to columns from queries on a single table, which may be a derived table.
- References to columns from queries on a join over multiple tables.
- References to columns from `DISTINCT` queries.
- References to columns in other tables, as long as the `SELECT` does not use `GROUP BY`. One side effect is that you must qualify references to nonunique column names.

References to columns from a `UNION` do not work reliably. To work around this restriction, rewrite the `UNION` as a derived table so that its rows can be treated as a single-table result set. For example, this statement is problematic:

```
INSERT INTO t1 (a, b)
SELECT c, d FROM t2
UNION
SELECT e, f FROM t3
ON DUPLICATE KEY UPDATE b = b + c;
```

Instead, use an equivalent statement that rewrites the `UNION` as a derived table:

```
INSERT INTO t1 (a, b)
SELECT * FROM
(SELECT c, d FROM t2
UNION
SELECT e, f FROM t3) AS dt
ON DUPLICATE KEY UPDATE b = b + c;
```

The technique of rewriting a query as a derived table also enables references to columns from `GROUP BY` queries.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements for the master and the slave to diverge. Thus, in MySQL 5.5.18 and later, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the error log when using statement-based mode and are written to the binary using the row-based format when using `MIXED` mode. In addition, beginning with MySQL 5.5.24, an `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)

See also [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

An `INSERT ... ON DUPLICATE KEY UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. For more information, see [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

13.2.5.3 INSERT DELAYED Statement

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the `INSERT` to complete. This is a common situation when you use MySQL for logging and you also periodically run `SELECT` and `UPDATE` statements that take a long time to complete.

When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using `INSERT DELAYED` is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note

`INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate `mysqld` forcibly (for example, with `kill -9`) or if `mysqld` dies unexpectedly, *any queued rows that have not been written to disk are lost*.

There are some constraints on the use of `DELAYED`:

- `INSERT DELAYED` works only with `MyISAM`, `MEMORY`, `ARCHIVE`, and `BLACKHOLE` tables. For engines that do not support `DELAYED`, an error occurs.
- An error occurs for `INSERT DELAYED` if used with a table that has been locked with `LOCK TABLES` because the insert must be handled by a separate thread, not by the session that holds the lock.
- For `MyISAM` tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and `INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with `MyISAM`.
- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.

- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.
- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.
- `INSERT DELAYED` is handled as a simple `INSERT` (that is, without the `DELAYED` option) whenever the value of `binlog_format` is `STATEMENT` or `MIXED`. (In the latter case, the statement does not trigger a switch to row-based logging, and so is logged using the statement-based format.)

This does not apply when using row-based binary logging mode (`binlog_format` set to `ROW`), in which `INSERT DELAYED` statements are always executed using the `DELAYED` option as specified, and logged as row-update events.

- `DELAYED` is ignored on slave replication servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on slaves. This is because `DELAYED` could cause the slave to have different data than the master.
- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
- `INSERT DELAYED` is not supported for views.
- `INSERT DELAYED` is not supported for partitioned tables.

The following describes in detail what happens when you use the `DELAYED` option to `INSERT` or `REPLACE`. In this description, the “thread” is the thread that received an `INSERT DELAYED` statement and “handler” is the thread that handles all `INSERT DELAYED` statements for a particular table.

- When a thread executes a `DELAYED` statement for a table, a handler thread is created to process all `DELAYED` statements for the table, if no such handler already exists.
- The thread checks whether the handler has previously acquired a `DELAYED` lock; if not, it tells the handler thread to do so. The `DELAYED` lock can be obtained even if other threads have a `READ` or `WRITE` lock on the table. However, the handler waits for all `ALTER TABLE` locks or `FLUSH TABLES` statements to finish, to ensure that the table structure is up to date.
- The thread executes the `INSERT` statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.
- The client cannot obtain from the server the number of duplicate rows or the `AUTO_INCREMENT` value for the resulting row, because the `INSERT` returns before the insert operation has been completed. (If you use the C API, the `mysql_info()` function does not return anything meaningful, for the same reason.)
- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.
- Each time that `delayed_insert_limit` rows are written, the handler checks whether any `SELECT` statements are still pending. If so, it permits these to execute before continuing.
- When the handler has no more rows in its queue, the table is unlocked. If no new `INSERT DELAYED` statements are received within `delayed_insert_timeout` seconds, the handler terminates.
- If more than `delayed_queue_size` rows are pending in a specific handler queue, the thread requesting `INSERT DELAYED` waits until there is room in the queue. This is done to ensure that `mysqld` does not use all memory for the delayed memory queue.
- The handler thread shows up in the MySQL process list with `delayed_insert` in the `Command` column. It is killed if you execute a `FLUSH TABLES` statement or kill it with `KILL thread_id`. However, before exiting, it first stores all queued rows into the table. During this time it does not

accept any new `INSERT` statements from other threads. If you execute an `INSERT DELAYED` statement after this, a new handler thread is created.

This means that `INSERT DELAYED` statements have higher priority than normal `INSERT` statements if there is an `INSERT DELAYED` handler running. Other update statements have to wait until the `INSERT DELAYED` queue is empty, someone terminates the handler thread (with `KILL thread_id`), or someone executes a `FLUSH TABLES`.

- The following status variables provide information about `INSERT DELAYED` statements.

| Status Variable | Meaning |
|---------------------------------------|---|
| <code>Delayed_insert_threads</code> | Number of handler threads |
| <code>Delayed_writes</code> | Number of rows written with <code>INSERT DELAYED</code> |
| <code>Not_flushed_delayed_rows</code> | Number of rows waiting to be written |

You can view these variables by issuing a `SHOW STATUS` statement or by executing a `mysqladmin extended-status` command.

13.2.6 LOAD DATA Statement

```
LOAD DATA
  [LOW_PRIORITY | CONCURRENT] [LOCAL]
  INFILE 'file_name'
  [REPLACE | IGNORE]
  INTO TABLE tbl_name
  [CHARACTER SET charset_name]
  [{FIELDS | COLUMNS}
   [TERMINATED BY 'string']
   [[OPTIONALLY] ENCLOSED BY 'char']
   [ESCAPED BY 'char']
  ]
  [LINES
   [STARTING BY 'string']
   [TERMINATED BY 'string']
  ]
  [IGNORE number {LINES | ROWS}]
  [(col_name_or_user_var
   [, col_name_or_user_var] ...)]
  [SET col_name={expr | DEFAULT},
   [, col_name={expr | DEFAULT}] ...]
```

The `LOAD DATA` statement reads rows from a text file into a table at a very high speed. `LOAD DATA` is the complement of `SELECT ... INTO OUTFILE`. (See [Section 13.2.9.1, “SELECT ... INTO Statement”](#).) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements.

You can also load data files by using the `mysqlimport` utility; see [Section 4.5.5, “mysqlimport — A Data Import Program”](#). `mysqlimport` operates by sending a `LOAD DATA` statement to the server.

For more information about the efficiency of `INSERT` versus `LOAD DATA` and speeding up `LOAD DATA`, see [Section 8.2.4.1, “Optimizing INSERT Statements”](#).

- [Miscellaneous Topics](#)

Partitioned Table Support

For partitioned tables using storage engines that employ table locks, such as [MyISAM](#), any locks caused by [LOAD DATA](#) perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as [InnoDB](#). For more information, see [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

Input File Name, Location, and Content Interpretation

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The `character_set_filesystem` system variable controls the interpretation of the file name character set.

The server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

[LOAD DATA](#) interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with [LOAD DATA](#).

Note

It is not possible to load data files that use the `ucs2`, `utf16`, or `utf32` character set.

Concurrency Considerations

If you use the `LOW_PRIORITY` modifier, execution of the [LOAD DATA](#) statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as [MyISAM](#), [MEMORY](#), and [MERGE](#)).

If you specify the `CONCURRENT` modifier with a [MyISAM](#) table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while [LOAD DATA](#) is executing. This modifier affects the performance of [LOAD DATA](#) a bit, even if no other thread is using the table at the same time.

For information about [LOAD DATA](#) in relation to replication, see [Section 17.4.1.17, “Replication and LOAD DATA”](#).

The `LOCAL` modifier affects expected location of the file and error handling, as described later. `LOCAL` works only if your server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, `LOCAL` does not work. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

The `LOCAL` modifier affects where the file is expected to be found:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.

When using `LOCAL` with `LOAD DATA`, a copy of the file is created in the directory where the MySQL server stores temporary files. See [Section B.4.3.5, “Where MySQL Stores Temporary Files”](#). Lack of sufficient space for the copy in this directory can cause the `LOAD DATA LOCAL` statement to fail.

- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
 - If the file name is an absolute path name, the server uses it as given.
 - If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server's data directory.
 - If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

In the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Non-`LOCAL` load operations read text files located on the server. For security reasons, such operations require that you have the `FILE` privilege. See [Section 6.2.2, “Privileges Provided by MySQL”](#). Also, non-`LOCAL` load operations are subject to the `secure_file_priv` system variable setting. If the variable value is a nonempty directory name, the file to be loaded must be located in that directory. If the variable value is empty (which is insecure), the file need only be readable by the server.

Using `LOCAL` is a bit slower than letting the server access the files directly, because the file contents must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE` privilege to load local files.

`LOCAL` also affects error handling:

- With `LOAD DATA`, data-interpretation and duplicate-key errors terminate the operation.
- With `LOAD DATA LOCAL`, data-interpretation and duplicate-key errors become warnings and the operation continues because the server has no way to stop transmission of the file in the middle of the operation. For duplicate-key errors, this is the same as if `IGNORE` is specified. `IGNORE` is explained further later in this section.

Duplicate-Key Handling

The `REPLACE` and `IGNORE` modifiers control handling of input rows that duplicate existing rows on unique key values:

- If you specify `REPLACE`, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 13.2.8, “REPLACE Statement”](#).
- If you specify `IGNORE`, rows that duplicate an existing row on a unique key value are discarded.
- If you do not specify either modifier, the behavior depends on whether the `LOCAL` modifier is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

Index Handling

To ignore foreign key constraints during the load operation, execute a `SET foreign_key_checks = 0` statement before executing `LOAD DATA`.

If you use `LOAD DATA` on an empty `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 8.2.4.1, “Optimizing INSERT Statements”](#).

Field and Line Handling

For both the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, [OPTIONALLY] `ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them. Arguments to these clauses are permitted to contain only ASCII characters.

If you specify no `FIELDS` or `LINES` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''
```

Backslash is the MySQL escape character within strings in SQL statements. Thus, to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences `'\t'` and `'\n'` specify tab and newline characters, respectively.

In other words, the defaults cause `LOAD DATA` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character `\` as escape sequences. For example, `\t`, `\n`, and `\\` signify tab, newline, and backslash, respectively. See the discussion of `FIELDS ESCAPED BY` later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use `\` to escape instances of tab, newline, or `\` that occur within field values.
- Write newlines at the ends of lines.

Note

For a text file generated on a Windows system, proper file reading might require `LINES TERMINATED BY '\r\n'` because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the input lines have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip the prefix *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be ("abc",1) and ("def",2). The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use `OPTIONALLY` before the `ENCLOSED BY` option.

Any of the field- or line-handling options can specify an empty string (''). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

FIELDS [OPTIONALLY] ENCLOSED BY controls quoting of fields. For output (`SELECT ... INTO OUTFILE`), if you omit the word **OPTIONALLY**, all fields are enclosed by the **ENCLOSED BY** character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string",100.20"
"2","a string containing a , comma",102.20"
"3","a string containing a \" quote",102.20"
"4","a string containing a \", quote and comma",102.20"
```

If you specify **OPTIONALLY**, the **ENCLOSED BY** character is used only to enclose values from columns that have a string data type (such as **CHAR**, **BINARY**, **TEXT**, or **ENUM**):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Occurrences of the **ENCLOSED BY** character within a field value are escaped by prefixing them with the **ESCAPED BY** character. Also, if you specify an empty **ESCAPED BY** value, it is possible to inadvertently generate output that cannot be read properly by **LOAD DATA**. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the **ENCLOSED BY** character, if present, is stripped from the ends of field values. (This is true regardless of whether **OPTIONALLY** is specified; **OPTIONALLY** has no effect on input interpretation.) Occurrences of the **ENCLOSED BY** character preceded by the **ESCAPED BY** character are interpreted as part of the current field value.

If the field begins with the **ENCLOSED BY** character, instances of that character are recognized as terminating a field value only if followed by the field or line **TERMINATED BY** sequence. To avoid ambiguity, occurrences of the **ENCLOSED BY** character within a field value can be doubled and are interpreted as a single instance of the character. For example, if **ENCLOSED BY ' ''** is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss     -> The "BIG" boss
The ""BIG"" boss   -> The ""BIG"" boss
```

FIELDS ESCAPED BY controls how to read or write special characters:

- For input, if the **FIELDS ESCAPED BY** character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using `\` for the escape character). The rules for **NULL** handling are described later in this section.

| Character | Escape Sequence |
|-----------------|---|
| <code>\0</code> | An ASCII NUL (<code>x'00'</code>) character |
| <code>\b</code> | A backspace character |
| <code>\n</code> | A newline (linefeed) character |
| <code>\r</code> | A carriage return character |
| <code>\t</code> | A tab character. |
| <code>\Z</code> | ASCII 26 (Control+Z) |
| <code>\N</code> | NULL |

For more information about `\`-escape syntax, see [Section 9.1.1, "String Literals"](#).

If the `FIELDS ESCAPED BY` character is empty, escape-sequence interpretation does not occur.

- For output, if the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:
 - The `FIELDS ESCAPED BY` character.
 - The `FIELDS [OPTIONALLY] ENCLOSED BY` character.
 - The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values, if the `ENCLOSED BY` character is empty or unspecified.
 - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte).

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is nonempty, lines are also terminated with `FIELDS TERMINATED BY`.
- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (``), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to `' '`. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later.

Note

Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `\`).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.
- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.
- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 11.5, "Data Type Default Values"](#).

Some cases are not supported by `LOAD DATA`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '' ENCLOSED BY ''
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA` to stop reading a field or line too early. This happens because `LOAD DATA` cannot properly determine where the field or line value ends.

Column List Specification

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
(col_name_or_user_var [, col_name_or_user_var] ...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

Input Preprocessing

Each `col_name_or_user_var` value is either a column name or a user variable. With user variables, the `SET` clause enables you to perform preprocessing transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @var1)
SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.

- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 11.5, “Data Type Default Values”](#).

An empty field value is interpreted different from a missing field:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 11.2, “Date and Time Data Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if `sql_mode` is set to `TRADITIONAL`, conversion of an empty value or a value such as `'x'` for a numeric column results in an error, not conversion to 0. (With `LOCAL` or `IGNORE`, warnings occur rather than errors, even with a restrictive `sql_mode` value, and the row is inserted using the same closest-value behavior used for nonrestrictive SQL modes. This occurs because the server has no way to stop transmission of the file in the middle of the operation.)

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded directly using binary notation (for example, `b'011010'`). To work around this, use the `SET` clause to strip off the leading `b'` and trailing `'` and perform a base-2 to base-10 conversion so that MySQL loads the values into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
b'10'
b'1111111'
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
      INTO TABLE bit_test (@var1)
      SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| BIN(b+0) |
+-----+
| 10      |
```

```
| 1111111 |
+-----+
2 rows in set (0.00 sec)
```

For `BIT` values in `0b` binary notation (for example, `0b011010`), use this `SET` clause instead to strip off the leading `0b`:

```
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

Statement Result Information

When the `LOAD DATA` statement finishes, it returns an information string in the following format:

```
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see [Section 13.2.5, “INSERT Statement”](#)), except that `LOAD DATA` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See [Section 13.7.5.41, “SHOW WARNINGS Statement”](#).

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See [Section 23.7.6.35, “mysql_info\(\)”](#).

Miscellaneous Topics

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

13.2.7 LOAD XML Statement

```
LOAD XML
[LOW_PRIORITY | CONCURRENT] [LOCAL]
INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE [db_name.]tbl_name
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<tagname>']
[IGNORE number {LINES | ROWS}]
[(field_name_or_user_var
[, field_name_or_user_var] ...)]
[SET col_name={expr | DEFAULT},
[, col_name={expr | DEFAULT}] ...]
```

The `LOAD XML` statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (`<` and `>`).

`LOAD XML` acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```
shell> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use `LOAD XML`. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

Prior to MySQL 5.5.46, `LOAD XML` did not handle empty XML elements in the form `<element/>` correctly. (Bug #67542, Bug #16171518)

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

- `LOW_PRIORITY` or `CONCURRENT`
- `LOCAL`
- `REPLACE` or `IGNORE`
- `CHARACTER SET`
- `SET`

See [Section 13.2.6, “LOAD DATA Statement”](#), for more information about these clauses.

`(field_name_or_user_var, ...)` is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with `@`. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first `number` rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```
USE test;

CREATE TABLE person (
  person_id INT NOT NULL PRIMARY KEY,
  fname VARCHAR(40) NULL,
  lname VARCHAR(40) NULL,
  created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```

<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
  <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
  <person><field name="person_id">5</field><field name="fname">Stoma</field>
    <field name="lname">Milu</field></person>
  <person><field name="person_id">6</field><field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field></person>
  <person person_id="7"><fname>Sungam</fname><lname>Dulbåd</lname></person>
  <person person_id="8" fname="Sreraf" lname="Encmelt"/>
</list>

```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```

mysql> LOAD XML LOCAL INFILE 'person.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';

Query OK, 8 rows affected (0.00 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```

ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)

```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```

mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likame | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
| 7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |
| 8 | Sreraf | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)

```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read using `LOAD XML`.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```

shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
<?xml version="1.0"?>

<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>

  <row>

```

```

<field name="person_id">2</field>
<field name="fname">Sajon</field>
<field name="lname">Rondela</field>
</row>

<row>
<field name="person_id">3</field>
<field name="fname">Likema</field>
<field name="lname">Örrtmons</field>
</row>

<row>
<field name="person_id">4</field>
<field name="fname">Slar</field>
<field name="lname">Manlanth</field>
</row>

<row>
<field name="person_id">5</field>
<field name="fname">Stoma</field>
<field name="lname">Nilu</field>
</row>

<row>
<field name="person_id">6</field>
<field name="fname">Nirtam</field>
<field name="lname">Sklöd</field>
</row>

<row>
<field name="person_id">7</field>
<field name="fname">Sungam</field>
<field name="lname">Dulbåd</field>
</row>

<row>
<field name="person_id">8</field>
<field name="fname">Sreraf</field>
<field name="lname">Encmelt</field>
</row>
</resultset>

```

Note

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See [Section 4.5.1, "mysql — The MySQL Command-Line Client"](#).

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```

mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likema | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+

```

```

|          7 | Sungam | Dulbád | 2007-07-13 16:18:47 |
|          8 | Sreraf | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)

```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

```

mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE person2\G
***** 1. row *****
      Table: person2
Create Table: CREATE TABLE `person2` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  PRIMARY KEY (`person_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+
| person_id | fname | lname |
+-----+-----+-----+
|          1 | Kapek | Sainnouine |
|          2 | Sajon | Rondela |
|          3 | Likema | Örrtmons |
|          4 | Slar | Manlanth |
|          5 | Stoma | Nilu |
|          6 | Nirtam | Sklöd |
|          7 | Sungam | Dulbád |
|          8 | Sreraf | Encmelt |
+-----+-----+-----+
8 rows in set (0.00 sec)

```

The order in which the fields are given within each row of the XML file does not affect the operation of `LOAD XML`; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a (*field_name_or_user_var, ...*) list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```

mysql> CREATE TABLE individual (
->   individual_id INT NOT NULL PRIMARY KEY,
->   name1 VARCHAR(40) NULL,
->   name2 VARCHAR(40) NULL,
->   made TIMESTAMP
-> );
Query OK, 0 rows affected (0.42 sec)

```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml'
-> INTO TABLE test.individual (@person_id, @fname, @lname, @created)
-> SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM individual;
+-----+-----+-----+-----+
| individual_id | name1 | name2 | made |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likema | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
| 7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |
| 8 | Srraf | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)
```

The names of the user variables *must* match those of the corresponding fields from the XML file, with the addition of the required `@` prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```
<?xml version="1.0"?>
<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>
  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
  </person>
</list>
```

You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql< TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql< SHOW CREATE TABLE person\G
***** 1. row *****
Table: person
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
```

```
`created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```
CREATE TABLE address (
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP
);
```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
|          1 | Robert | Jones | 2007-07-24 17:37:06 |
|          2 | Mary  | Smith | 2007-07-24 17:37:06 |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE address
-> ROWS IDENTIFIED BY '<address>';
Query OK, 3 rows affected (0.00 sec)
Records: 3 Deleted: 0 Skipped: 0 Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```
mysql> SELECT * FROM address;
+-----+-----+-----+-----+-----+-----+
| address_id | person_id | street          | zip  | city          | created |
+-----+-----+-----+-----+-----+-----+
|          1 |          1 | Mill Creek Road | 45365 | Sidney       | 2007-07-24 17:37:37 |
|          2 |          1 | Main Street     | 28681 | Taylorsville | 2007-07-24 17:37:37 |
|          3 |          2 | River Road     | 80239 | Denver       | 2007-07-24 17:37:37 |
+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

Security Considerations. As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

Important

Revoking the `FILE` privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML` statement (as well as the `LOAD_FILE()` function; it does *not* prevent the user from executing `LOAD XML LOCAL`. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the `FILE` privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, any locks caused by `LOAD XML` perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

13.2.8 REPLACE Statement

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [(col_name [, col_name] ...)]
  {VALUES | VALUE} (value_list) [, (value_list)] ...

REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  SET assignment_list

REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [(col_name [, col_name] ...)]
  SELECT ...

value:
  {expr | DEFAULT}

value_list:
  value [, value] ...

assignment:
  col_name = value

assignment_list:
  assignment [, assignment] ...
```

`REPLACE` works exactly like `INSERT`, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. See [Section 13.2.5, “INSERT Statement”](#).

`REPLACE` is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL—that either inserts or *updates*—see [Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”](#).

**Note**

`REPLACE` makes sense only if a table has a `PRIMARY KEY` or `UNIQUE` index. Otherwise, it becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
 - a. Delete from the table the conflicting row that has the duplicate key value
 - b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_xxx` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the master and the slave to diverge. For this reason, in MySQL 5.5.18 and later, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the error log when using statement-based mode, and are written to the binary log using the row-based format when using `MIXED` mode. See also [Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication"](#).

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see [Section 19.5.1, "Partitioning Keys, Primary Keys, and Unique Keys"](#)). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```
CREATE TABLE test (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
```

```

data VARCHAR(64) DEFAULT NULL,
ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
PRIMARY KEY (id)
);

```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```

mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+-----+-----+-----+
| id | data | ts                |
+-----+-----+-----+
| 1 | New | 2014-08-20 18:47:42 |
+-----+-----+-----+
1 row in set (0.00 sec)

```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```

CREATE TABLE test2 (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id, ts)
);

```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```

mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+-----+-----+-----+
| id | data | ts                |
+-----+-----+-----+
| 1 | Old | 2014-08-20 18:47:00 |
| 1 | New | 2014-08-20 18:47:42 |
+-----+-----+-----+
2 rows in set (0.00 sec)

```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

A `REPLACE` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. For more information, see [Section 19.5.4, "Partitioning and Table-Level Locking"](#).

13.2.9 SELECT Statement

```

SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr] ...
  [into_option]
  [FROM table_references]
  [WHERE where_condition]

```

```

[GROUP BY {col_name | expr | position}
 [ASC | DESC], ... [WITH ROLLUP]]
[HAVING where_condition]
[ORDER BY {col_name | expr | position}
 [ASC | DESC], ...]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
[PROCEDURE procedure_name(argument_list)]
[into_option]
[FOR UPDATE | LOCK IN SHARE MODE]

into_option: {
  INTO OUTFILE 'file_name'
    [CHARACTER SET charset_name]
    export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name] ...
}

```

SELECT is used to retrieve rows selected from one or more tables, and can include **UNION** statements and subqueries. See [Section 13.2.9.3, “UNION Clause”](#), and [Section 13.2.10, “Subqueries”](#).

The most commonly used clauses of **SELECT** statements are these:

- Each *select_expr* indicates a column that you want to retrieve. There must be at least one *select_expr*.
- *table_references* indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 13.2.9.2, “JOIN Clause”](#).
- The **WHERE** clause, if given, indicates the condition or conditions that rows must satisfy to be selected. *where_condition* is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no **WHERE** clause.

In the **WHERE** expression, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Section 9.5, “Expressions”](#), and [Chapter 12, *Functions and Operators*](#).

SELECT can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify **DUAL** as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

DUAL is purely for the convenience of people who require that all **SELECT** statements should have **FROM** and possibly other clauses. MySQL may ignore the clauses. MySQL does not require **FROM DUAL** if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a **HAVING** clause must come after any **GROUP BY** clause and before any **ORDER BY** clause. The **INTO** clause, if present, can appear in any position indicated by the syntax description, but within a given statement can appear only once, not in multiple positions. For more information about **INTO**, see [Section 13.2.9.1, “SELECT ... INTO Statement”](#).

The list of *select_expr* terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use *****-shorthand:

- A select list consisting only of a single unqualified ***** can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```

- `tbl_name.*` can be used as a qualified shorthand to select all columns from the named table:

```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
```

- Use of an unqualified `*` with other items in the select list may produce a parse error. To avoid this problem, use a qualified `tbl_name.*` reference

```
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other `SELECT` clauses:

- A `select_expr` can be given an alias using `AS alias_name`. The alias is used as the expression's column name and can be used in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. For example:

```
SELECT CONCAT(last_name, ' ', first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The `AS` keyword is optional when aliasing a `select_expr` with an identifier. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ' ', first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two `select_expr` expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See [Section B.4.4.4, "Problems with Column Aliases"](#).

- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 13.2.9.2, "JOIN Clause"](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see [Section 8.9.3, "Index Hints"](#).

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 5.1.7, "Server System Variables"](#).

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference unless the reference would be ambiguous. See [Section 9.2.2, "Identifier Qualifiers"](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`. These statements are equivalent:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
```

```
WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in [ORDER BY](#) and [GROUP BY](#) clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;

SELECT college, region, seed FROM tournament
ORDER BY 2, 3;
```

To sort in reverse order, add the [DESC](#) (descending) keyword to the name of the column in the [ORDER BY](#) clause that you are sorting by. The default is ascending order; this can be specified explicitly using the [ASC](#) keyword.

If [ORDER BY](#) occurs within a subquery and also is applied in the outer query, the outermost [ORDER BY](#) takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```
(SELECT ... ORDER BY a) ORDER BY a DESC;
```

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- MySQL extends the [GROUP BY](#) clause so that you can also specify [ASC](#) and [DESC](#) after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- If you use [GROUP BY](#), output rows are sorted according to the [GROUP BY](#) columns as if you had an [ORDER BY](#) for the same columns. To avoid the overhead of sorting that [GROUP BY](#) produces, add [ORDER BY NULL](#):

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

Relying on implicit [GROUP BY](#) sorting (that is, sorting in the absence of [ASC](#) or [DESC](#) designators) is deprecated. To produce a given sort order, use explicit [ASC](#) or [DESC](#) designators for [GROUP BY](#) columns or provide an [ORDER BY](#) clause.

- When you use [ORDER BY](#) or [GROUP BY](#) to sort a column in a [SELECT](#), the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.
- MySQL extends the use of [GROUP BY](#) to permit selecting fields that are not mentioned in the [GROUP BY](#) clause. If you are not getting the results that you expect from your query, please read the description of [GROUP BY](#) found in [Section 12.17](#), “Aggregate (GROUP BY) Functions”.
- [GROUP BY](#) permits a [WITH ROLLUP](#) modifier. See [Section 12.17.2](#), “GROUP BY Modifiers”.
- The [HAVING](#) clause is applied nearly last, just before items are sent to the client, with no optimization. ([LIMIT](#) is applied after [HAVING](#).)

The SQL standard requires that [HAVING](#) must reference only columns in the [GROUP BY](#) clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits [HAVING](#) to refer to columns in the [SELECT](#) list and columns in outer subqueries as well.

If the [HAVING](#) clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

```
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also permits `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the `select_expr` values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the `select_expr` values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as for `ORDER BY`.)
- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
 - Within prepared statements, `LIMIT` parameters can be specified using `?` placeholder markers.
 - Within stored programs, `LIMIT` parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5; # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a subquery and also is applied in the outer query, the outermost `LIMIT` takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see [Section 8.4.2.4, “Using PROCEDURE ANALYSE”](#), which describes `ANALYSE`, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.

A `PROCEDURE` clause is not permitted in a `UNION` statement.

- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see [Section 13.2.9.1, “SELECT ... INTO Statement”](#).
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See [Section 14.10.2.4, “Locking Reads”](#).

Following the `SELECT` keyword, you can use a number of modifiers that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and modifiers beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` modifiers specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. `DISTINCTROW` is a synonym for `DISTINCT`.
- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See [Section 13.2.9.2, “JOIN Clause”](#).

`STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by `EXPLAIN`. See [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#). This exception may not apply to `const` or `system` tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`).

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`, MySQL directly uses disk-based temporary tables if they are created, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements. For `SQL_SMALL_RESULT`, MySQL uses in-memory temporary tables to store the resulting table instead of using sorting. This should not normally be needed.
- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 12.15, “Information Functions”](#).
- The `SQL_CACHE` and `SQL_NO_CACHE` modifiers affect caching of query results in the query cache (see [Section 8.10.3, “The MySQL Query Cache”](#)). `SQL_CACHE` tells MySQL to store the result in the query cache if it is cacheable and the value of the `query_cache_type` system variable is `2` or `DEMAND`. With `SQL_NO_CACHE`, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result. (Due to a limitation in the parser, a space character must precede and follow the `SQL_NO_CACHE` keyword; a non-space such as a newline causes the server to check the query cache to see whether the result is already cached.)

These two modifiers are mutually exclusive and an error occurs if they are both specified. Also, these modifiers are not permitted in subqueries (including subqueries in the `FROM` clause), and `SELECT` statements in unions other than the first `SELECT`.

For views, `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query. For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of a view referred to by the query.

A `SELECT` from a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. For more information, see [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

13.2.9.1 SELECT ... INTO Statement

The `SELECT ... INTO` form of `SELECT` enables a query result to be stored in variables or written to a file:

- `SELECT ... INTO var_list` selects column values and stores them into variables.
- `SELECT ... INTO OUTFILE` writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.
- `SELECT ... INTO DUMPFILE` writes a single row to a file without any formatting.

A given `SELECT` statement can contain at most one `INTO` clause, although as shown by the `SELECT` syntax description (see [Section 13.2.9, “SELECT Statement”](#)), the `INTO` can appear in different positions:

- Before `FROM`. Example:

```
SELECT * INTO @myvar FROM t1;
```

- Before a trailing locking clause. Example:

```
SELECT * FROM t1 INTO @myvar FOR UPDATE;
```

An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context. There are also constraints on the use of `INTO` within `UNION` statements; see [Section 13.2.9.3, “UNION Clause”](#).

For the `INTO var_list` variant:

- `var_list` names a list of one or more variables, each of which can be a user-defined variable, stored procedure or function parameter, or stored program local variable. (Within a prepared `SELECT ... INTO var_list` statement, only user-defined variables are permitted; see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).)
- The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

```
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case-sensitive. See [Section 9.4, “User-Defined Variables”](#).

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being modified. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended to enable dumping a table to a text file on the server host. To create the resulting file on some other host, `SELECT ... INTO OUTFILE` normally is unsuitable because there is no way to write a path to the file relative to the server host file system, unless the location of the file on the remote host can be accessed using a network-mapped path on the server host file system.

Alternatively, if the MySQL client software is installed on the remote host, you can use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on that host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, so will the output data file and it may not be possible to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA` statement. For information about the `FIELDS` and `LINES` clauses, including their default values and permissible values, see [Section 13.2.6, “LOAD DATA Statement”](#).

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some pagers.

The resulting file need not conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful for selecting a `BLOB` value and storing it in a file.

Note

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see [Section 20.4.5, “Event Scheduler Status”](#).

13.2.9.2 JOIN Clause

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references:
  escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference:
  table_reference
  | { OJ table_reference }

table_reference:
  table_factor
  | joined_table

table_factor:
  tbl_name [[AS] alias] [index_hint_list]
  | table_subquery [AS] alias
  | ( table_references )

joined_table:
  table_reference [INNER | CROSS] JOIN table_factor [join_specification]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON search_condition
```

```

| table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_specification
| table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_specification:
  ON search_condition
| USING (join_column_list)

join_column_list:
  column_name [, column_name] ...

index_hint_list:
  index_hint [, index_hint] ...

index_hint:
  USE {INDEX|KEY}
  [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
| {IGNORE|FORCE} {INDEX|KEY}
  [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
  index_name [, index_name] ...

```

A table reference is also known as a join expression.

The syntax of *table_factor* is extended in MySQL in comparison with standard SQL. The standard accepts only *table_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of *table_reference* items is considered as equivalent to an inner join. For example:

```

SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
      ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)

```

is equivalent to:

```

SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
      ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)

```

In MySQL, **JOIN**, **CROSS JOIN**, and **INNER JOIN** are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. **INNER JOIN** is used with an **ON** clause, **CROSS JOIN** is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See [Section 8.2.1.6, “Nested Join Optimization”](#).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see [Section 8.9.3, “Index Hints”](#). The `optimizer_switch` system variable is another way to influence optimizer use of indexes. See [Section 8.9.2, “Switchable Optimizations”](#).

The following list describes general factors to take into account when writing joins:

- A table reference can be aliased using *tbl_name AS alias_name* or *tbl_name alias_name*:

```

SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
  FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;

```

- A *table_subquery* is also known as a derived table or subquery in the **FROM** clause. See [Section 13.2.10.8, “Derived Tables”](#). Such subqueries *must* include an alias to give the subquery result a table name. A trivial example follows:

```

SELECT * FROM (SELECT 1, 2, 3) AS t1;

```

- The maximum number of tables that can be referenced in a single join is 61.

- `INNER JOIN` and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The `search_condition` used with `ON` is any conditional expression of the form that can be used in a `WHERE` clause. Generally, the `ON` clause serves for conditions that specify how to join tables, and the `WHERE` clause restricts which rows to include in the result set.
- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
   FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
   WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See [Section 8.2.1.7, “Outer Join Optimization”](#).

- The `USING(join_column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1, c2, c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.
- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.
- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
   FROM { OJ left_tbl LEFT OUTER JOIN right_tbl
         ON left_tbl.id = right_tbl.id }
   WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

The parser does not permit nested `{ OJ ... }` constructs (which are not legal ODBC syntax, anyway). Queries that use such constructs should be rewritten.

- `STRAIGHT_JOIN` is similar to `JOIN`, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```
SELECT * FROM table1, table2;

SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;
```

```
SELECT * FROM table1 LEFT JOIN table2 USING (id);

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard:

- Redundant columns of a `NATURAL` join do not appear. Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first `SELECT` statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second `SELECT` statement, column `j` is named in the `USING` clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
```

Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN x IS NOT NULL THEN x ELSE y END)
```

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-`NULL` column if one of the two columns is always `NULL`. If neither or both columns are `NULL`, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a `JOIN`. Suppose that the tables `t1(a, b)` and `t2(a, c)` have the following contents:

```
t1    t2
----  ----
1 x   2 z
2 y   3 w
```

Then, for this join, column `a` contains the values of `t1.a`:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| 1     | x     | NULL  |
| 2     | y     | z     |
+-----+-----+-----+
```

By contrast, for this join, column `a` contains the values of `t2.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+-----+-----+-----+
| a     | c     | b     |
+-----+-----+-----+
| 2     | z     | y     |
| 3     | w     | NULL  |
+-----+-----+-----+
```

Compare those results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 1     | x     | NULL  | NULL  |
| 2     | y     | 2     | z     |
+-----+-----+-----+-----+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 2     | y     | 2     | z     |
| NULL  | NULL  | 3     | w     |
+-----+-----+-----+-----+
```

- A `USING` clause can be rewritten as an `ON` clause that compares corresponding columns. However, although `USING` and `ON` are similar, they are not quite the same. Consider the following two queries:

```
a LEFT JOIN b USING (c1, c2, c3)
a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3
```

With respect to determining which rows satisfy the join condition, both joins are semantically identical.

With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1, b.c1)` is the same as either `a.c1` or `b.c1` because both columns will have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column is omitted from the result.

- An `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
```

```
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

The statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. To enable the join to be processed, rewrite the statement as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- `JOIN` has higher precedence than the comma operator (`,`), so the join expression `t1, t2 JOIN t3` is interpreted as `(t1, (t2 JOIN t3))`, not as `((t1, t2) JOIN t3)`. This affects statements that use an `ON` clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The `JOIN` takes precedence over the comma operator, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error.

To enable the join to be processed, use either of these strategies:

- Group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1, t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

- Avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The same precedence interpretation also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of `NATURAL` or `USING` joins, whereas the standard disallows that.

13.2.9.3 UNION Clause

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

`UNION` combines the result from multiple `SELECT` statements into a single result set. The result set column names are taken from the column names of the first `SELECT` statement.

Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.) If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all of the `SELECT` statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
```

```
+-----+
| a      |
| bbbbbbbbbb |
+-----+
```

The `SELECT` statements are normal select statements, but with the following restrictions:

- `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`. If you specify it for the first `SELECT`, it has no effect. If you specify it for any subsequent `SELECT` statements, a syntax error results.
- Only the last `SELECT` statement can use an `INTO` clause. However, the entire `UNION` result is written to the `INTO` output destination.

By default, duplicate rows are removed from `UNION` results. The optional `DISTINCT` keyword has the same effect but makes it explicit. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

Use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, `ORDER BY` in this context typically is used in conjunction with `LIMIT`, to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect, anyway.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements is permitted, but the second fails with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, colla;
```

Use of an additional column also enables you to determine which `SELECT` each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

13.2.10 Subqueries

A subquery is a `SELECT` statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1 ...` is the *outer query* (or *outer statement*), and `(SELECT column1 FROM t2)` is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
   WHERE NOT EXISTS
    (SELECT * FROM t3
     WHERE ROW(5*t2.s1,77)=
      (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
       (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, joins, index hints, `UNION` constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`.

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and (because subqueries can be used in the `SET` clause) `LOAD DATA`.

For information about how the optimizer handles subqueries, see [Section 8.2.2, “Subquery Optimization”](#). For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see [Section 13.2.10.12, “Restrictions on Subqueries”](#).

13.2.10.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be `NULL`, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value ('abcde') that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is `NULL`. For the subquery just shown, if `t1` were empty, the result would be `NULL` even though `s2` is `NOT NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct (`SELECT column1 FROM t1`), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is `2` because there is a row in `t2` containing a column `s1` that has a value of `2`.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

13.2.10.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where `comparison_operator` is one of these operators:

```
= > < >= <= <> != <=>
```

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See [Section 13.2.10.5, "Row Subqueries"](#).

13.2.10.3 Subqueries with ANY, IN, or SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where `comparison_operator` is one of these operators:

```
= > < >= <= <> !=
```

The `ANY` keyword, which must follow a comparison operator, means "return `TRUE` if the comparison is `TRUE` for `ANY` of the values in the column that the subquery returns." For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(21, 14, 7)` because there is a value `7` in `t2` that is less than `10`. The expression is `FALSE` if table `t2` contains `(20, 10)`, or if table `t2` is empty. The expression is `unknown` (that is, `NULL`) if table `t2` contains `(NULL, NULL, NULL)`.

When used with a subquery, the word `IN` is an alias for `= ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

`IN` and `= ANY` are not synonyms when used with an expression list. `IN` can take an expression list, but `= ANY` cannot. See [Section 12.3.2, "Comparison Functions and Operators"](#).

`NOT IN` is not an alias for `<> ANY`, but for `<> ALL`. See [Section 13.2.10.4, "Subqueries with ALL"](#).

The word `SOME` is an alias for `ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word `SOME` is rare, but this example shows why it might be useful. To most people, the English phrase "a is not equal to any b" means "there is no b which is equal to a," but that is not what is meant by the SQL syntax. The syntax means "there is some b to which a is not equal." Using `<> SOME` instead helps ensure that everyone understands the true meaning of the query.

13.2.10.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word **ALL**, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ALL** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table **t1** containing (10). The expression is **TRUE** if table **t2** contains (-5,0,+5) because 10 is greater than all three values in **t2**. The expression is **FALSE** if table **t2** contains (12,6,NULL,-100) because there is a single value 12 in table **t2** that is greater than 10. The expression is *unknown* (that is, **NULL**) if table **t2** contains (0,NULL,1).

Finally, the expression is **TRUE** if table **t2** is empty. So, the following expression is **TRUE** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing NULL values* and *empty tables* are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

NOT IN is an alias for **<> ALL**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

13.2.10.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
= > < >= <= <> != <=>
```

Here are two examples:

```
SELECT * FROM t1
  WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
  WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table **t2** contains a single row with **id = 10**, the subquery returns a single row. If this row has **col3** and **col4** values equal to the **col1** and **col2** values of any rows in **t1**, the **WHERE** expression is **TRUE** and each query returns those **t1** rows. If the **t2** row **col3** and **col4** values are not equal the **col1** and **col2** values of any **t1** row, the expression is **FALSE** and the query returns an empty result set. The expression is *unknown* (that is, **NULL**) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see [Section 12.3.2, “Comparison Functions and Operators”](#).

The expressions (1,2) and **ROW(1,2)** are sometimes called *row constructors*. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```
SELECT column1,column2,column3
FROM t1
WHERE (column1,column2,column3) IN
      (SELECT column1,column2,column3 FROM t2);
```

For more information about the optimizer and row constructors, see [Section 8.2.1.15, “Row Constructor Expression Optimization”](#)

13.2.10.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
              WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in `Stores`”? But it is easier to say that a nested `NOT EXISTS` answers the question “is `x TRUE` for all `y`?”

13.2.10.7 Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
                     WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5,6)` is not equal to `(5,7)`), so the expression as a whole is `FALSE`.

Scoping rule: MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
                  WHERE x.column1 = (SELECT column1 FROM t3
                                    WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

13.2.10.8 Derived Tables

A derived table is an expression that generates a table within the scope of a query `FROM` clause. For example, a subquery in a `SELECT` statement `FROM` clause is a derived table:

```
SELECT ... FROM (subquery) [AS] tbl_name ...
```

The `[AS] tbl_name` clause is mandatory because every table in a `FROM` clause must have a name. Any columns in the derived table must have unique names.

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1, '1', 1.0);
INSERT INTO t1 VALUES (2, '2', 2.0);
SELECT sb1, sb2, sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result:

```
+-----+-----+-----+
| sb1 | sb2 | sb3 |
+-----+-----+-----+
| 2 | 2 | 4 |
+-----+-----+-----+
```

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

A derived table can return a scalar, column, row, or table.

Derived tables are subject to these restrictions:

- A derived table cannot be a correlated subquery.
- A derived table cannot contain references to other tables of the same `SELECT`.
- A derived table cannot contain outer references. This is a MySQL restriction, not a restriction of the SQL standard.

Subqueries in the `FROM` clause are executed even for the `EXPLAIN` statement (that is, derived temporary tables are materialized). This occurs because upper-level queries need information about all tables during the optimization phase, and the table represented by a subquery in the `FROM` clause is unavailable unless the subquery is executed.

It is possible under certain circumstances that using `EXPLAIN SELECT` will modify table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:

```
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
BEGIN
    INSERT INTO t2 VALUES (p1);
    RETURN p1;
END;
```

Referencing the function directly in an `EXPLAIN SELECT` has no effect on `t2`, as shown here:

```
mysql> SELECT * FROM t2;
Empty set (0.02 sec)

mysql> EXPLAIN SELECT f1(5)\G
***** 1. row *****
    id: 1
  select_type: SIMPLE
    table: NULL
    type: NULL
possible_keys: NULL
    key: NULL
  key_len: NULL
    ref: NULL
    rows: NULL
  Extra: No tables used
```

```
1 row in set (0.01 sec)
```

```
mysql> SELECT * FROM t2;
Empty set (0.01 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
***** 1. row *****
      id: 1
    select_type: PRIMARY
      table: NULL
      type: NULL
possible_keys: NULL
      key: NULL
     key_len: NULL
       ref: NULL
      rows: NULL
     filtered: NULL
      Extra: No tables used
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1249 | Select 2 was reduced during optimization |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well, with the result that `t2` is modified:

```
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2\G
***** 1. row *****
      id: 1
    select_type: PRIMARY
      table: <derived2>
      type: system
possible_keys: NULL
      key: NULL
     key_len: NULL
       ref: NULL
      rows: 1
     Extra:
***** 2. row *****
      id: 1
    select_type: PRIMARY
      table: a1
      type: ALL
possible_keys: NULL
      key: NULL
     key_len: NULL
       ref: NULL
      rows: 1
     Extra:
***** 3. row *****
      id: 2
    select_type: DERIVED
      table: NULL
      type: NULL
possible_keys: NULL
      key: NULL
     key_len: NULL
       ref: NULL
      rows: NULL
     Extra: No tables used
3 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM t2;
+-----+
| c1    |
+-----+
| 5     |
+-----+
1 row in set (0.00 sec)
```

This also means that an `EXPLAIN SELECT` statement such as the one shown here may take a long time to execute because the `BENCHMARK()` function is executed once for each row in `t1`:

```
EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));
```

13.2.10.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

```
ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"
```

This means that MySQL does not support statements of the following form:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

- Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See [Section 13.2.10.5, "Row Subqueries"](#).

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

13.2.10.10 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also [Section 8.2.2, “Subquery Optimization”](#).

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
  (SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (
  SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2
  WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See [Section 13.2.10.11, “Rewriting Subqueries as Joins”](#).
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE (column1, column2) IN (SELECT column1, column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
```

```
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.
- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.
- Use `= ANY` rather than `EXISTS`.
- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1
WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1
WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See [Section 12.15, “Information Functions”](#).

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <=} (uncorrelated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also [MySQL Internals: How MySQL Transforms Subqueries](#).

13.2.10.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
FROM table1 LEFT JOIN table2 ON table1.id=table2.id
WHERE table2.id IS NULL;
```

A [LEFT \[OUTER\] JOIN](#) can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table [DELETE](#) statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table [UPDATE](#) statements are also supported. See [Section 13.2.2, “DELETE Statement”](#), and [Section 13.2.11, “UPDATE Statement”](#).

13.2.10.12 Restrictions on Subqueries

- Subquery optimization for [IN](#) is not as effective as for the `=` operator or for the [IN\(value_list\)](#) operator.

A typical case for poor [IN](#) subquery performance is when the subquery returns a small number of rows but the outer query returns a large number of rows to be compared to the subquery result.

The problem is that, for a statement that uses an [IN](#) subquery, the optimizer rewrites it as a correlated subquery. Consider the following statement that uses an uncorrelated subquery:

```
SELECT ... FROM t1 WHERE t1.a IN (SELECT b FROM t2);
```

The optimizer rewrites the statement to a correlated subquery:

```
SELECT ... FROM t1 WHERE EXISTS (SELECT 1 FROM t2 WHERE t2.b = t1.a);
```

If the inner and outer queries return M and N rows, respectively, the execution time becomes on the order of $O(M \times N)$, rather than $O(M+N)$ as it would be for an uncorrelated subquery.

An implication is that an [IN](#) subquery can be much slower than a query written using an [IN\(value_list\)](#) operator that lists the same values that the subquery would return.

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

```
DELETE FROM t WHERE ... (SELECT ... FROM t ...);
UPDATE t ... WHERE col = (SELECT ... FROM t ...);
{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);
```

Exception: The preceding prohibition does not apply if for the modified table you are using a derived table and that derived table is materialized rather than merged into the outer query. Example:

```
UPDATE t ... WHERE col = (SELECT * FROM (SELECT ... FROM t...) AS _t ...);
```

Here the result from the derived table is materialized as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

- Row comparison operations are only partially supported:
 - For `expr [NOT] IN subquery`, `expr` can be an n -tuple (specified using row constructor syntax) and the subquery can return rows of n -tuples. The permitted syntax is therefore more specifically expressed as `row_constructor [NOT] IN table_subquery`

- For `expr op {ALL|ANY|SOME} subquery`, `expr` must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of *n*-tuples, this is supported:

```
(expr_1, ..., expr_n) [NOT] IN table_subquery
```

But this is not supported:

```
(expr_1, ..., expr_n) op {ALL|ANY|SOME} subquery
```

The reason for supporting row comparisons for `IN` but not for the others is that `IN` is implemented by rewriting it as a sequence of `=` comparisons and `AND` operations. This approach cannot be used for `ALL`, `ANY`, or `SOME`.

- Subqueries in the `FROM` clause cannot be correlated subqueries. They are materialized in whole (evaluated to produce a result set) before evaluating the outer query, so they cannot be evaluated per row of the outer query.
- MySQL does not support `LIMIT` in subqueries for certain subquery operators:

```
mysql> SELECT * FROM t1
      WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1);
ERROR 1235 (42000): This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'
```

- The optimizer is more mature for joins than for subqueries, so in many cases a statement that uses a subquery can be executed more efficiently if you rewrite it as a join.

An exception occurs for the case where an `IN` subquery can be rewritten as a `SELECT DISTINCT` join. Example:

```
SELECT col FROM t1 WHERE id_col IN (SELECT id_col2 FROM t2 WHERE condition);
```

That statement can be rewritten as follows:

```
SELECT DISTINCT col FROM t1, t2 WHERE t1.id_col = t2.id_col AND condition;
```

But in this case, the join requires an extra `DISTINCT` operation and is not more efficient than the subquery.

- MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if `f()` inserts rows, the following query can modify data:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

This behavior is an extension to the SQL standard. In MySQL, it can produce nondeterministic results because `f()` might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

For statement-based or mixed-format replication, one implication of this indeterminism is that such a query can produce different results on the master and its slaves.

13.2.11 UPDATE Statement

`UPDATE` is a DML statement that modifies rows in a table.

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
  SET assignment_list
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

```

value:
    {expr | DEFAULT}

assignment:
    col_name = value

assignment_list:
    assignment [, assignment] ...

```

Multiple-table syntax:

```

UPDATE [LOW_PRIORITY] [IGNORE] table_references
    SET assignment_list
    [WHERE where_condition]

```

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the `ORDER BY` clause is specified, the rows are updated in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, `UPDATE` updates rows in each table named in `table_references` that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, `ORDER BY` and `LIMIT` cannot be used.

`where_condition` is an expression that evaluates to true for each row to be updated. For expression syntax, see [Section 9.5, “Expressions”](#).

`table_references` and `where_condition` are specified as described in [Section 13.2.9, “SELECT Statement”](#).

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

The `UPDATE` statement supports the following modifiers:

- With the `LOW_PRIORITY` modifier, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- With the `IGNORE` modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

In MySQL 5.5.18 and later, `UPDATE IGNORE` statements, including those having an `ORDER BY` clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439) See [Section 17.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#), for more information.

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table `UPDATE` assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared `NOT NULL` by setting to `NULL`, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is `0` for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types. See [Section 11.5, “Data Type Default Values”](#).

`UPDATE` returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the `UPDATE`.

You can use `LIMIT row_count` to restrict the scope of the `UPDATE`. A `LIMIT` clause is a rows-matched restriction. The statement stops as soon as it has found `row_count` rows that satisfy the `WHERE` clause, whether or not they actually were changed.

If an `UPDATE` statement includes an `ORDER BY` clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an `ORDER BY` clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform `UPDATE` operations covering multiple tables. However, you cannot use `ORDER BY` or `LIMIT` with a multiple-table `UPDATE`. The `table_references` clause lists the tables involved in the join. Its syntax is described in [Section 13.2.9.2, “JOIN Clause”](#). Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table `UPDATE` statements can use any type of join permitted in `SELECT` statements, such as `LEFT JOIN`.

If you use a multiple-table `UPDATE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the `ON UPDATE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly. See [Section 13.1.17.6, “FOREIGN KEY Constraints”](#).

You cannot update a table and select from the same table in a subquery.

An `UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. For more information, see [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

13.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”](#). XA transaction support enables MySQL to participate in distributed transactions as well. See [Section 13.3.7, “XA Transactions”](#).

13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Statements

```
START TRANSACTION [WITH CONSISTENT SNAPSHOT]
BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

These statements provide control over use of [transactions](#):

- [START TRANSACTION](#) or [BEGIN](#) start a new transaction.
- [COMMIT](#) commits the current transaction, making its changes permanent.
- [ROLLBACK](#) rolls back the current transaction, canceling its changes.
- [SET autocommit](#) disables or enables the default autocommit mode for the current session.

By default, MySQL runs with [autocommit](#) mode enabled. This means that, when not otherwise inside a transaction, each statement is atomic, as if it were surrounded by [START TRANSACTION](#) and [COMMIT](#). You cannot use [ROLLBACK](#) to undo the effect; however, if an error occurs during statement execution, the statement is rolled back.

To disable autocommit mode implicitly for a single series of statements, use the [START TRANSACTION](#) statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With [START TRANSACTION](#), autocommit remains disabled until you end the transaction with [COMMIT](#) or [ROLLBACK](#). The autocommit mode then reverts to its previous state.

You can also begin a transaction like this:

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

The [WITH CONSISTENT SNAPSHOT](#) option starts a [consistent read](#) for storage engines that are capable of it. This applies only to [InnoDB](#). The effect is the same as issuing a [START TRANSACTION](#) followed by a [SELECT](#) from any [InnoDB](#) table. See [Section 14.10.2.3, “Consistent Nonlocking Reads”](#). The [WITH CONSISTENT SNAPSHOT](#) option does not change the current transaction [isolation level](#), so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is [REPEATABLE READ](#). For all other isolation levels, the [WITH CONSISTENT SNAPSHOT](#) clause is ignored. As of MySQL 5.5.34, a warning is generated when the [WITH CONSISTENT SNAPSHOT](#) is ignored.

Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a [START TRANSACTION](#) statement from the client. See [Chapter 23, Connectors and APIs](#), or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the [autocommit](#) variable to zero, changes to transaction-safe tables (such as those for [InnoDB](#) or [NDBCLUSTER](#)) are not made permanent immediately. You must use [COMMIT](#) to store your changes to disk or [ROLLBACK](#) to ignore the changes.

[autocommit](#) is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the [autocommit](#) system variable at [Section 5.1.7, “Server System Variables”](#).

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax and is the recommended way to start an ad-hoc transaction.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See [Section 13.6.1, “BEGIN ... END Compound Statement”](#).

Note

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See [Section 5.1.7, “Server System Variables”](#).

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The new transaction also uses the same access mode (`READ WRITE` or `READ ONLY`) as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#), for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as `InnoDB`), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)
- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.
- If you issue a `ROLLBACK` statement after updating a nontransactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception:** Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that modifications to the nontransactional tables are replicated.) See [Section 5.4.4, “The Binary Log”](#).

You can change the isolation level for transactions with the `SET TRANSACTION` statement. See [Section 13.3.6, “SET TRANSACTION Statement”](#).

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

Note

In MySQL 5.5, `BEGIN`, `COMMIT`, and `ROLLBACK` are not affected by `--replicate-do-db` or `--replicate-ignore-db` rules.

13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a `COMMIT` before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction because it cannot be rolled back anyway. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- **Data definition language (DDL) statements that define or modify database objects.** `ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER SERVER`, `ALTER TABLE`, `ALTER VIEW`, `CREATE DATABASE`, `CREATE EVENT`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE SERVER`, `CREATE TABLE`, `CREATE TRIGGER`, `CREATE VIEW`, `DROP DATABASE`, `DROP EVENT`, `DROP INDEX`, `DROP PROCEDURE`, `DROP SERVER`, `DROP TABLE`, `DROP TRIGGER`, `DROP VIEW`, `RENAME TABLE`, `TRUNCATE TABLE`.

`ALTER FUNCTION`, `CREATE FUNCTION` and `DROP FUNCTION` also cause an implicit commit when used with stored functions, but not with user-defined functions. (`ALTER FUNCTION` can only be used with stored functions.)

`CREATE TABLE` and `DROP TABLE` statements do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `ALTER TABLE` and `CREATE INDEX`, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use `CREATE TEMPORARY TABLE` and then roll back the transaction, the table remains in existence.

The `CREATE TABLE` statement in `InnoDB` is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

`CREATE TABLE ... SELECT` causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for `CREATE TEMPORARY TABLE ... SELECT`.)

- **Statements that implicitly use or modify tables in the `mysql` database.** `CREATE USER`, `DROP USER`, `GRANT`, `RENAME USER`, `REVOKE`, `SET PASSWORD`.
- **Transaction-control and locking statements.** `BEGIN`, `LOCK TABLES`, `SET autocommit = 1` (if the value is not already 1), `START TRANSACTION`, `UNLOCK TABLES`.

`UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES` to acquire nontransactional table locks. A commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See [Section 13.6.1, “BEGIN ... END Compound Statement”](#).

- **Data loading statements.** `LOAD DATA`. `LOAD DATA` causes an implicit commit only for tables using the `NDB` storage engine.
- **Administrative statements.** `ANALYZE TABLE`, `CACHE INDEX`, `CHECK TABLE`, `LOAD INDEX INTO CACHE`, `OPTIMIZE TABLE`, `REPAIR TABLE`.

13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Statements

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does *not* release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

13.3.5 LOCK TABLES and UNLOCK TABLES Statements

```

LOCK TABLES
  tbl_name [[AS] alias] lock_type
  [, tbl_name [[AS] alias] lock_type] ...

lock_type: {
  READ [LOCAL]
  | [LOW_PRIORITY] WRITE
}

UNLOCK TABLES

```

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail in [Table-Locking Restrictions and Conditions](#).

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked.

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in [LOCK TABLES and Triggers](#).

`UNLOCK TABLES` explicitly releases any table locks held by the current session. `LOCK TABLES` implicitly releases any table locks held by the current session before acquiring new locks.

Another use for `UNLOCK TABLES` is to release the global read lock acquired with the `FLUSH TABLES WITH READ LOCK` statement, which enables you to lock all tables in all databases. See [Section 13.7.6.3, “FLUSH Statement”](#). (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`. For sessions holding a `READ` lock, `DROP TABLE` and `TRUNCATE TABLE` operations are not permitted.

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is permitted (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

- [Table Lock Acquisition](#)
- [Table Lock Release](#)
- [Interaction of Table Locking and Transactions](#)
- [LOCK TABLES and Triggers](#)
- [Table-Locking Restrictions and Conditions](#)

Table Lock Acquisition

To acquire table locks within the current session, use the `LOCK TABLES` statement, which acquires metadata locks (see [Section 8.11.4, “Metadata Locking”](#)).

The following lock types are available:

`READ [LOCAL]` lock:

- The session that holds the lock can read the table (but not write it).

- Multiple sessions can acquire a `READ` lock for the table at the same time.
- Other sessions can read the table without explicitly acquiring a `READ` lock.
- The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See [Section 8.11.3, “Concurrent Inserts”](#).) However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For `InnoDB` tables, `READ LOCAL` is the same as `READ`.

`[LOW_PRIORITY] WRITE` lock:

- The session that holds the lock can read and write the table.
- Only the session that holds the lock can access the table. No other session can access it until the lock is released.
- Lock requests for the table by other sessions block while the `WRITE` lock is held.
- The `LOW_PRIORITY` modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use `WRITE` without `LOW_PRIORITY` instead.

`WRITE` locks normally have higher priority than `READ` locks to ensure that updates are processed as soon as possible. This means that if one session obtains a `READ` lock and then another session requests a `WRITE` lock, subsequent `READ` lock requests wait until the session that requested the `WRITE` lock has obtained the lock and released it. (An exception to this policy can occur for small values of the `max_write_lock_count` system variable; see [Section 8.11.4, “Metadata Locking”](#).)

If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+-----+
| COUNT(*) |
+-----+
|          3 |
+-----+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
```

```
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

Note

`LOCK TABLES` or `UNLOCK TABLES`, when applied to a partitioned table, always locks or unlocks the entire table. See [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

Table Lock Release

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with `UNLOCK TABLES`.
- If a session issues a `LOCK TABLES` statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with `START TRANSACTION`), an implicit `UNLOCK TABLES` is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see [Interaction of Table Locking and Transactions](#).)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks will no longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See [Section 23.7.19, “C API Automatic Reconnection Control”](#).

Note

If you use `ALTER TABLE` on a locked table, it may become unlocked. For example, if you attempt a second `ALTER TABLE` operation, the result may be an error `Table 'tbl_name' was not locked with LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also [Section B.4.6.1, “Problems with ALTER TABLE”](#).

Interaction of Table Locking and Transactions

`LOCK TABLES` and `UNLOCK TABLES` interact with the use of transactions as follows:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.
- `UNLOCK TABLES` implicitly commits any active transaction, but only if `LOCK TABLES` has been used to acquire table locks. For example, in the following set of statements, `UNLOCK TABLES` releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ... ;
```

```
UNLOCK TABLES;
```

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.
- `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See [Section 13.7.6.3, “FLUSH Statement”](#).
- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).
- The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as `InnoDB` tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

When you call `LOCK TABLES`, `InnoDB` internally takes its own table lock, and MySQL takes its own table lock. `InnoDB` releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then `InnoDB` releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. `InnoDB` does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.

LOCK TABLES and Triggers

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken at the same time as those acquired explicitly with the `LOCK TABLES` statement.
- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.
- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table's appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers will also be locked. Suppose that `t1` has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

- `t1` is locked for writing per the `WRITE` lock request.

- `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.
- `t3` is locked for reading because it is only read from within the trigger.
- `t4` is locked for writing because it might be updated within the trigger.

Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See [Section 13.7.6.4, “KILL Statement”](#).

Do *not* lock any tables that you are using with `INSERT DELAYED`. An `INSERT DELAYED` in this case results in an error because the insert must be handled by a separate thread, not by the session which holds the lock.

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

The following statements are prohibited while a `LOCK TABLES` statement is in effect: `CREATE TABLE`, `CREATE TABLE ... LIKE`, `CREATE VIEW`, `DROP VIEW`, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
```

If you want to explicitly place a `WRITE` lock on any of those tables with a `LOCK TABLES` statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single `UPDATE` statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of `MyISAM` tables, it is much faster to lock the tables you are going to use. Locking `MyISAM` tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until `UNLOCK TABLES` is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a `READ`-locked table (including the one holding the lock) and no session can access a `WRITE`-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use `LOCK TABLES` if you want to ensure that no other session modifies the tables between a `SELECT` and an `UPDATE`. The example shown here requires `LOCK TABLES` to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
```

```
SET total_value=sum_from_previous_statement
WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without `LOCK TABLES`, it is possible that another session might insert a new row in the `trans` table between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer SET value=value+new_value`) or the `LAST_INSERT_ID()` function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See [Section 12.14, “Locking Functions”](#).

See [Section 8.11.1, “Internal Locking Methods”](#), for more information on locking policy.

13.3.6 SET TRANSACTION Statement

```
SET [GLOBAL | SESSION] TRANSACTION ISOLATION LEVEL level

level: {
  REPEATABLE READ
  | READ COMMITTED
  | READ UNCOMMITTED
  | SERIALIZABLE
}
```

This statement sets the transaction isolation level, used for operations on `InnoDB` tables.

- [Transaction Isolation Levels](#)
- [Transaction Isolation Level Scope](#)

Transaction Isolation Levels

To set the transaction isolation level, use an `ISOLATION LEVEL level` clause.

The default isolation level is `REPEATABLE READ`. Other permitted values are `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE`. For information about these isolation levels, see [Section 14.10.2.1, “Transaction Isolation Levels”](#).

Transaction Isolation Level Scope

You can set the isolation level globally, for the current session, or for the next transaction only:

- With the `GLOBAL` keyword:
 - The statement applies globally for all subsequent sessions.
 - Existing sessions are unaffected.
- With the `SESSION` keyword:
 - The statement applies to all subsequent transactions performed within the current session.
 - The statement is permitted within transactions, but does not affect the current ongoing transaction.
 - If executed between transactions, the statement overrides any preceding statement that sets the next-transaction isolation level.
- Without any `SESSION` or `GLOBAL` keyword:
 - The statement applies only to the next single transaction performed within the session.

- Subsequent transactions revert to using the session isolation level.
- The statement is not permitted within transactions:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction isolation level can't be changed
while a transaction is in progress
```

A change to the global isolation level requires the `SUPER` privilege. Any session is free to change its session isolation level (even in the middle of a transaction), or the isolation level for its next transaction (prior to the start of that transaction).

To set the global isolation level at server startup, use the `--transaction-isolation=level` option on the command line or in an option file. Values of `level` for this option use dashes rather than spaces, so the permissible values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. For example, to set the isolation level to `REPEATABLE READ`, use these lines in the `[mysqld]` section of an option file:

```
[mysqld]
transaction-isolation = REPEATABLE-READ
```

It is possible to set or check the global and session transaction isolation levels at runtime by using the `tx_isolation` system variable:

```
SET GLOBAL tx_isolation='REPEATABLE-READ';
SET SESSION tx_isolation='SERIALIZABLE';
SELECT @@GLOBAL.tx_isolation, @@SESSION.tx_isolation;
```

13.3.7 XA Transactions

Support for XA transactions is available for the `InnoDB` storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in [Section 13.3.7.3, “Restrictions on XA Transactions”](#).

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need to be linked against a recent client library. Older client libraries also will work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 supports XA directly (by means of a class interface that handles the XA SQL statement interface for you).

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, `SERIALIZABLE` may be preferred if your applications are sensitive to read phenomena. `REPEATABLE READ` may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and

processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”

- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

13.3.7.1 XA Transaction SQL Statements

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
```

```
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER
```

For `XA START`, the `JOIN` and `RESUME` clauses are recognized but have no effect.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is recognized but has no effect.

Each XA statement begins with the `XA` keyword, and most of them require an `xid` value. An `xid` is an XA transaction identifier. It indicates which transaction the statement applies to. `xid` values are supplied by the client, or generated by the MySQL server. An `xid` value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

`gtrid` is a global transaction identifier, `bqual` is a branch qualifier, and `formatID` is a number that identifies the format used by the `gtrid` and `bqual` values. As indicated by the syntax, `bqual` and `formatID` are optional. The default `bqual` value is `' '` if not given. The default `formatID` value is 1 if not given.

`gtrid` and `bqual` must be string literals, each up to 64 bytes (not characters) long. `gtrid` and `bqual` can be specified in several ways. You can use a quoted string (`'ab'`), hex string (`X'6162'`, `0x6162`), or bit value (`b'nnnn'`).

`formatID` is an unsigned integer.

The `gtrid` and `bqual` values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write `gtrid` and `bqual` as hex strings.

`xid` values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own `xid` values in a list of values returned by the `XA RECOVER` statement.

`XA START xid` starts an XA transaction with the given `xid` value. Each XA transaction must have a unique `xid` value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the `gtrid` and `bqual` values. All following XA statements for the XA transaction must be specified using the same `xid` value as that given in the `XA START` statement. If you use any of those statements but specify an `xid` value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same `gtrid` value in the `xid` value. For this reason, `gtrid` values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The `bqual` part of the `xid` value must be different for each XA transaction within a global transaction. (The requirement that `bqual` values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The `XA RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See [Section 13.3.7.2, "XA Transaction States"](#).) The output includes a row for each such XA transaction on the server, regardless of which client started it.

`XA RECOVER` output rows look like this (for an example `xid` value consisting of the parts `'abc'`, `'def'`, and 7):

```
mysql> XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|          7 |             3 |             3 | abcdef |
+-----+-----+-----+-----+
```

The output columns have the following meanings:

- `formatID` is the `formatID` part of the transaction `xid`
- `gtrid_length` is the length in bytes of the `gtrid` part of the `xid`
- `bqual_length` is the length in bytes of the `bqual` part of the `xid`
- `data` is the concatenation of the `gtrid` and `bqual` parts of the `xid`

13.3.7.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.
2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.
3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:
 - `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point will include the transaction's `xid` value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.
 - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The `xid` value will not be listed by `XA RECOVER` because the transaction terminates.
4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

13.3.7.3 Restrictions on XA Transactions

XA transaction support is limited to the [InnoDB](#) storage engine.

For “external XA,” a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For “Internal XA”, storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for [InnoDB](#).

For [XA START](#), the [JOIN](#) and [RESUME](#) clauses are recognized but have no effect.

For [XA END](#) the [SUSPEND \[FOR MIGRATE\]](#) clause is recognized but has no effect.

The requirement that the [bqual](#) part of the [xid](#) value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

If an XA transaction has reached the [PREPARED](#) state and the MySQL server is killed (for example, with `kill -9` on Unix) or shuts down abnormally, the transaction can be continued after the server restarts. However, if the client reconnects and commits the transaction, the transaction will be absent from the binary log even though it has been committed. This means the data and the binary log have gone out of synchrony. An implication is that XA cannot be used safely together with replication.

It is possible that the server will roll back a pending XA transaction, even one that has reached the [PREPARED](#) state. This happens if a client connection terminates and the server continues to run, or if clients are connected and the server shuts down gracefully. (In the latter case, the server marks each connection to be terminated, and then rolls back the [PREPARED](#) XA transaction associated with it.) It should be possible to commit or roll back a [PREPARED](#) XA transaction, but this cannot be done without changes to the binary logging mechanism.

[FLUSH TABLES WITH READ LOCK](#) is not compatible with XA transactions.

13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. One group of statements controls master servers, the other controls slave servers.

13.4.1 SQL Statements for Controlling Master Servers

This section discusses statements for managing master replication servers. [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#), discusses statements for managing slave servers.

In addition to the statements described here, the following [SHOW](#) statements are used with master servers in replication. For information about these statements, see [Section 13.7.5, “SHOW Statements”](#).

- [SHOW BINARY LOGS](#)
- [SHOW BINLOG EVENTS](#)
- [SHOW MASTER STATUS](#)
- [SHOW SLAVE HOSTS](#)

13.4.1.1 PURGE BINARY LOGS Statement

```
PURGE { BINARY | MASTER } LOGS {
  TO 'log_name'
  | BEFORE datetime_expr
```

}

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see [Section 5.4.4, “The Binary Log”](#)).

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2019-04-02 22:46:26';
```

The `BEFORE` variant's `datetime_expr` argument should evaluate to a `DATETIME` value (a value in `'YYYY-MM-DD hh:mm:ss'` format).

This statement is safe to run while slaves are replicating. You need not stop them. If you have an active slave that currently is reading one of the log files you are trying to delete, this statement does nothing and fails with an error. However, if a slave is not connected and you happen to purge one of the log files it has yet to read, the slave will be unable to replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the master server with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the slaves. This is the target file. If all the slaves are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.1.7, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

`PURGE BINARY LOGS TO` and `PURGE BINARY LOGS BEFORE` both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the `PURGE BINARY LOGS` statement that failed.

13.4.1.2 RESET MASTER Statement

```
RESET MASTER
```

Deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file. This statement is intended to be used only when the master is started for the first time.

Important

The effects of `RESET MASTER` differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET MASTER` removes *all* binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.
2. `RESET MASTER` is *not* intended to be used while any replication slaves are running. The behavior of `RESET MASTER` when used while slaves are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replication slaves are running.

See also [Section 13.4.1.1, “PURGE BINARY LOGS Statement”](#).

`RESET MASTER` can prove useful when you first set up the master and the slave, so that you can verify the setup as follows:

1. Start the master and slave, and start replication (see [Section 17.1.1, “How to Set Up Replication”](#)).
2. Execute a few test queries on the master.
3. Check that the queries were replicated to the slave.
4. When replication is running correctly, issue `STOP SLAVE` followed by `RESET SLAVE` on the slave, then verify that any unwanted data no longer exists on the slave.
5. Issue `RESET MASTER` on the master to clean up the test queries.

After verifying the setup and getting rid of any unwanted and log files generated by testing, you can start the slave and begin replicating.

13.4.1.3 SET sql_log_bin Statement

```
SET sql_log_bin = {OFF|ON}
```

The `sql_log_bin` variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the master you do not want replicated to the slave.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.8.1, “System Variable Privileges”](#).

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

As of MySQL 5.5.41, the global `sql_log_bin` variable is read only and cannot be modified. The global scope is deprecated and will be removed in a future MySQL release. Prior to 5.5.41, `sql_log_bin` can be set as a global or session variable. Setting `sql_log_bin` globally is only detected when a new session is started. Any sessions previously running are not impacted when setting `sql_log_bin` globally.

Warning

Incorrect use of `sql_log_bin` with a global scope means any changes made in an already running session are *still* being recorded to the binary log and therefore replicated. Exercise extreme caution using `sql_log_bin` with a global scope as the above situation could cause unexpected results including replication failure.

13.4.2 SQL Statements for Controlling Slave Servers

This section discusses statements for managing slave replication servers. [Section 13.4.1, “SQL Statements for Controlling Master Servers”](#), discusses statements for managing master servers.

In addition to the statements described here, `SHOW SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replication slaves. For information about these statements, see [Section 13.7.5.35, “SHOW SLAVE STATUS Statement”](#), and [Section 13.7.5.33, “SHOW RELAYLOG EVENTS Statement”](#).

13.4.2.1 CHANGE MASTER TO Statement

```
CHANGE MASTER TO option [, option] ...

option:
  MASTER_BIND = 'interface_name'
  MASTER_HOST = 'host_name'
  MASTER_USER = 'user_name'
  MASTER_PASSWORD = 'password'
  MASTER_PORT = port_num
  MASTER_CONNECT_RETRY = interval
  MASTER_HEARTBEAT_PERIOD = interval
  MASTER_LOG_FILE = 'master_log_name'
  MASTER_LOG_POS = master_log_pos
  RELAY_LOG_FILE = 'relay_log_name'
  RELAY_LOG_POS = relay_log_pos
  MASTER_SSL = {0|1}
  MASTER_SSL_CA = 'ca_file_name'
  MASTER_SSL_CAPATH = 'ca_directory_name'
  MASTER_SSL_CERT = 'cert_file_name'
  MASTER_SSL_KEY = 'key_file_name'
  MASTER_SSL_CIPHER = 'cipher_list'
  MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
  IGNORE_SERVER_IDS = (server_id_list)

server_id_list:
  [server_id [, server_id] ... ]
```

`CHANGE MASTER TO` changes the parameters that the slave server uses for connecting to the master server, for reading the master binary log, and reading the slave relay log. It also updates the contents of the `master.info` and `relay-log.info` files. `CHANGE MASTER TO` requires the `SUPER` privilege.

To use `CHANGE MASTER TO`, the slave replication threads must be stopped (use `STOP SLAVE` if necessary).

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change. For example, if the password to connect to your MySQL master has changed, you just need to issue these statements to tell the slave about the new password:

```
STOP SLAVE; -- if replication was running
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
START SLAVE; -- if you want to restart replication
```

`MASTER_HOST`, `MASTER_USER`, `MASTER_PASSWORD`, and `MASTER_PORT` provide information to the slave about how to connect to its master:

- `MASTER_HOST` and `MASTER_PORT` are the host name (or IP address) of the master host and its TCP/IP port.

Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

If you specify the `MASTER_HOST` or `MASTER_PORT` option, the slave assumes that the master server is different from before (even if the option value is the same as its current value.) In this case, the old values for the master binary log file name and position are considered no longer

applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE= ''` and `MASTER_LOG_POS=4` are silently appended to it.

Setting `MASTER_HOST= ''` (that is, setting its value explicitly to an empty string) is *not* the same as not setting `MASTER_HOST` at all. Beginning with MySQL 5.5, trying to set `MASTER_HOST` to an empty string fails with an error. Previously, setting `MASTER_HOST` to an empty string caused `START SLAVE` subsequently to fail. (Bug #28796)

- `MASTER_USER` and `MASTER_PASSWORD` are the user name and password of the account to use for connecting to the master.

In MySQL 5.5.20 and later, `MASTER_USER` cannot be made empty; setting `MASTER_USER = ''` or leaving it unset when setting a value for `MASTER_PASSWORD` causes an error (Bug #13427949).

The password used for a MySQL Replication slave account in a `CHANGE MASTER TO` statement is limited to 32 characters in length; if the password is longer, the statement succeeds, but any excess characters are silently truncated. This is an issue specific to MySQL Replication, which is fixed in MySQL 5.7. (Bug #11752299, Bug #43439)

The text of a running `CHANGE MASTER TO` statement, including values for `MASTER_USER` and `MASTER_PASSWORD`, can be seen in the output of a concurrent `SHOW PROCESSLIST` statement.

The `MASTER_SSL_XXX` options provide information about using SSL for the connection. They correspond to the `--ssl-xxx` options described in [Command Options for Encrypted Connections](#), and [Section 17.3.7, “Setting Up Replication to Use Encrypted Connections”](#). These options can be changed even on slaves that are compiled without SSL support. They are saved to the `master.info` file, but are ignored if the slave does not have SSL support enabled.

`MASTER_CONNECT_RETRY` specifies how many seconds to wait between connect retries. The default is 60. The *number* of reconnection attempts is limited by the `--master-retry-count` server option; for more information, see [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).

The `MASTER_BIND` option is available in MySQL NDB Cluster 7.2 and later, but is not supported in mainline MySQL 5.5.

`MASTER_BIND` is for use on replication slaves having multiple network interfaces, and determines which of the slave's network interfaces is chosen for connecting to the master.

`MASTER_HEARTBEAT_PERIOD` sets the interval in seconds between replication heartbeats. Whenever the master's binary log is updated with an event, the waiting period for the next heartbeat is reset. *interval* is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Heartbeats are sent by the master only if there are no unsent events in the binary log file for a period longer than *interval*.

Setting *interval* to 0 disables heartbeats altogether. The default value for *interval* is equal to the value of `slave_net_timeout` divided by 2.

Setting `@@GLOBAL.slave_net_timeout` to a value less than that of the current heartbeat interval results in a warning being issued. The effect of issuing `RESET SLAVE` on the heartbeat interval is to reset it to the default value.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. `RELAY_LOG_FILE` and `RELAY_LOG_POS` are the coordinates at which the slave SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` is specified, the slave uses the last coordinates of the *slave SQL thread* before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

`CHANGE MASTER TO` deletes all relay log files and starts a new one, unless you specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In that case, relay log files are kept; the `relay_log_purge` global variable is set silently to 0.

Prior to MySQL 5.5, `RELAY_LOG_FILE` required an absolute path. In MySQL 5.5, the path can be relative, in which case the path is assumed to be relative to the slave's data directory. (Bug #12190)

`IGNORE_SERVER_IDS` was added in MySQL 5.5. This option takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE MASTER TO` statement that you issue on server 4 to tell it to use server 2 as its master instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

When a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ( );
```

`RESET SLAVE ALL` has no effect on the server ID list. This issue is fixed in MySQL 5.7. (Bug #18816897)

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

Also beginning with MySQL 5.5, the `master.info` file and the output of `SHOW SLAVE STATUS` are extended to provide the list of servers that are currently ignored. For more information, see [Section 17.2.2.2, "Slave Status Logs"](#), and [Section 13.7.5.35, "SHOW SLAVE STATUS Statement"](#).

Beginning with MySQL 5.5.5, invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the slave's state prior to execution.

`CHANGE MASTER TO` is useful for setting up a slave when you have the snapshot of the master and have recorded the master binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the slave to synchronize it with the master, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the slave to specify the coordinates at which the slave should begin reading the master binary log.

The following example changes the master server the slave uses and establishes the master binary log coordinates from which the slave begins reading. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.example.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='big3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay log files that you want it to execute again for some reason. To do this, the master need not

be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

The following table shows the maximum permissible length for the string-valued options.

| Option | Maximum Length |
|--------------------------------|----------------|
| <code>MASTER_HOST</code> | 60 |
| <code>MASTER_USER</code> | 16 |
| <code>MASTER_PASSWORD</code> | 32 |
| <code>MASTER_LOG_FILE</code> | 255 |
| <code>RELAY_LOG_FILE</code> | 255 |
| <code>MASTER_SSL_CA</code> | 255 |
| <code>MASTER_SSL_CAPATH</code> | 255 |
| <code>MASTER_SSL_CERT</code> | 255 |
| <code>MASTER_SSL_KEY</code> | 255 |
| <code>MASTER_SSL_CIPHER</code> | 511 |

13.4.2.2 MASTER_POS_WAIT() Statement

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos [, timeout])
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See [Section 12.18, “Miscellaneous Functions”](#), for a full description.

13.4.2.3 RESET SLAVE Statement

```
RESET SLAVE [ALL]
```

`RESET SLAVE` makes the slave forget its replication position in the master's binary log. This statement is meant to be used for a clean start: It deletes the `master.info` and `relay-log.info` files, all the relay log files, and starts a new relay log file. To use `RESET SLAVE`, the slave replication threads must be stopped (use `STOP SLAVE` if necessary).

Note

All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a `STOP SLAVE` statement or if the slave is highly loaded.)

In MySQL 5.5 (unlike the case in MySQL 5.1 and earlier), `RESET SLAVE` does not change any replication connection parameters such as master host, master port, master user, or master password, which are retained in memory. This means that `START SLAVE` can be issued without requiring a `CHANGE MASTER TO` statement following `RESET SLAVE`.

Connection parameters are reset if the slave `mysqld` is shut down following `RESET SLAVE`. In MySQL 5.5.16 and later, you can instead use `RESET SLAVE ALL` to reset these connection parameters (Bug #11809016).

`RESET SLAVE ALL` does not clear the `IGNORE_SERVER_IDS` list set by `CHANGE MASTER TO`. This issue is fixed in MySQL 5.7. (Bug #18816897)

If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the slave.

**Note**

When used on an NDB Cluster replication slave SQL node, `RESET SLAVE` clears the `mysql.ndb_apply_status` table. You should keep in mind when using this statement that `ndb_apply_status` uses the NDB storage engine and so is shared by all SQL nodes attached to the slave cluster.

13.4.2.4 SET GLOBAL `sql_slave_skip_counter` Statement

```
SET GLOBAL sql_slave_skip_counter = N
```

This statement skips the next *N* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave threads are not running. Otherwise, it produces an error.

When using this statement, it is important to understand that the binary log is actually organized as a sequence of groups known as *event groups*. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

**Note**

A single transaction can contain changes to both transactional and nontransactional tables.

When you use `SET GLOBAL sql_slave_skip_counter` to skip events and the result is in the middle of a group, the slave continues to skip events until it reaches the end of the group. Execution then starts with the next event group.

13.4.2.5 START SLAVE Statement

```
START SLAVE [thread_types]

START SLAVE [SQL_THREAD] UNTIL
  MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos

START SLAVE [SQL_THREAD] UNTIL
  RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos

thread_types:
  [thread_type [, thread_type] ... ]

thread_type: IO_THREAD | SQL_THREAD
```

`START SLAVE` with no *thread_type* options starts both of the slave threads. The I/O thread reads events from the master server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. `START SLAVE` requires the `SUPER` privilege.

If `START SLAVE` succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary log, or some other problem). `START SLAVE` does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with `SHOW SLAVE STATUS`.

`START SLAVE` sends an acknowledgment to the user after both the I/O thread and the SQL thread have started. However, the I/O thread may not yet have connected. For this reason, a successful `START SLAVE` causes `SHOW SLAVE STATUS` to show `Slave_SQL_Running=Yes`, but this does not guarantee that `Slave_IO_Running=Yes` (because `Slave_IO_Running=Yes` only if the I/O thread is running *and connected*). For more information, see [Section 13.7.5.35, "SHOW SLAVE STATUS Statement"](#), and [Section 17.1.4.1, "Checking Replication Status"](#).

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start.

An `UNTIL` clause may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary log or in the slave relay log. When the SQL thread reaches that point, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued.

For an `UNTIL` clause, you must specify both a log file name and position. Do not mix master and relay log options.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate an event. For example, if an unwise `DROP TABLE` statement was executed on the master, you can use `UNTIL` to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master binary log or slave relay log, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE START`. This usage is still accepted in MySQL 5.5 for backward compatibility, but is deprecated and is removed in MySQL 5.6.

13.4.2.6 STOP SLAVE Statement

```
STOP SLAVE [thread_types]

thread_types:
  [thread_type [, thread_type] ... ]

thread_type: IO_THREAD | SQL_THREAD
```

Stops the slave threads. `STOP SLAVE` requires the `SUPER` privilege. Recommended best practice is to execute `STOP SLAVE` on the slave before stopping the slave server (see [Section 5.1.14](#), “The Server Shutdown Process”, for more information).

When using the row-based logging format. You should execute `STOP SLAVE` on the slave prior to shutting down the slave server if you are replicating any tables that use a nontransactional storage engine (see the *Note* later in this section). In MySQL 5.5.9 and later, you can also use `STOP SLAVE SQL_THREAD` for this purpose.

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped.

If the current replication event group has modified one or more nontransactional tables, `STOP SLAVE` waits for up to 60 seconds for the event group to complete, unless you issue a `KILL QUERY` or `KILL CONNECTION` statement for the slave SQL thread. If the event group remains incomplete after the timeout, an error message is logged. (Bug #319, Bug #38205)

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE STOP`. This usage is still accepted in MySQL 5.5 for backward compatibility, but is deprecated and is removed in MySQL 5.6.

13.5 Prepared Statements

MySQL 5.5 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol, provided that you use an appropriate client programming interface. Candidate interfaces include the MySQL C API client library (for C programs), MySQL Connector/J (for Java programs), and MySQL Connector/NET. For example, the C API provides a set of function calls that make up its prepared statement API. See [Section 23.7.7, “C API Prepared Statements”](#). Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysql_i` extension, available in PHP 5.0 and later.

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that enables you to send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library. The only requirement is that you be able to connect to a server that is recent enough to support SQL syntax for prepared statements.

SQL syntax for prepared statements is intended to be used for situations such as these:

- You want to test how prepared statements work in your application before coding it.
- An application has problems executing prepared statements and you want to determine interactively what the problem is.
- You want to create a test case that describes a problem you are having with prepared statements, so that you can file a bug report.
- You need to use prepared statements but do not have access to a programming API that supports them.

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see [Section 13.5.1, “PREPARE Statement”](#)).
- `EXECUTE` executes a prepared statement (see [Section 13.5.2, “EXECUTE Statement”](#)).
- `DEALLOCATE PREPARE` releases a prepared statement (see [Section 13.5.3, “DEALLOCATE PREPARE Statement”](#)).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          5 |
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```

mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;

```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```

mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);

mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);

mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+-----+
| a |
+-----+
|  4 |
|  8 |
| 11 |
| 32 |
| 80 |
+-----+

mysql> DEALLOCATE PREPARE stmt3;

```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

The following SQL statements can be used as prepared statements:

```

ALTER TABLE
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
COMMIT
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE

```

```

REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE | QUERY CACHE}
REVOKE
SELECT
SET
SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
TRUNCATE TABLE
UNINSTALL PLUGIN
UPDATE

```

Other statements are not supported in MySQL 5.5.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in [Section 20.8, “Restrictions on Stored Programs”](#).

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 13.5.4, “Automatic Prepared Statement Reparation”](#).

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See [Section 13.2.9, “SELECT Statement”](#).

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 5.5. See [Section 13.2.1, “CALL Statement”](#), for an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

Prepared statements use the query cache under the conditions described in [Section 8.10.3.1, “How the Query Cache Operates”](#).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see [Section 13.2.1, “CALL Statement”](#).

13.5.1 PREPARE Statement

```
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a SQL statement and assigns it a name, *stmt_name*, by which to refer to the statement later. The prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`. For examples, see [Section 13.5, “Prepared Statements”](#).

Statement names are not case-sensitive. *preparable_stmt* is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which has several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See [Section 23.7.19, “C API Automatic Reconnection Control”](#).
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see [Section 9.4, “User-Defined Variables”](#).

13.5.2 EXECUTE Statement

```
EXECUTE stmt_name
  [USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see [Section 13.5, “Prepared Statements”](#).

13.5.3 DEALLOCATE PREPARE Statement

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error.

For examples, see [Section 13.5, “Prepared Statements”](#).

13.5.4 Automatic Prepared Statement Re-preparation

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic re-preparation of the statement when it is next executed. This applies to prepared statements processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client/server protocol (using the `mysql_stmt_prepare()` C API function).

The server attempts re-preparation up to three times. An error occurs if all attempts fail.

Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Re-preparation also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Table content changes (for example, with `INSERT` or `UPDATE`) do not cause re-preparation, nor do `SELECT` statements.

Re-preparation is automatic, but to the extent that it occurs, diminishes prepared statement performance.

Re-preparation uses the default database and SQL mode that were in effect for the original preparation.

The `Com_stmt_reprepare` status variable tracks the number of re-preparations.

13.6 Compound-Statements

This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see [Chapter 20, *Stored Objects*](#)).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

13.6.1 BEGIN ... END Compound Statement

```
[begin_label:] BEGIN
  [statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The `statement_list` itself is optional, so the empty compound statement (`BEGIN END`) is legal.

`BEGIN ... END` blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. In the `mysql` command-line client, this is handled with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) permit `;` to be used in a program body. For an example, see [Section 20.1, “Defining Stored Programs”](#).

A `BEGIN ... END` block can be labeled. See [Section 13.6.2, “Statement Labels”](#).

The optional `[NOT] ATOMIC` clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

**Note**

Within all stored programs, the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

13.6.2 Statement Labels

```
[begin_label:] BEGIN
  [statement_list]
END [end_label]

[begin_label:] LOOP
  statement_list
END LOOP [end_label]

[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

Labels are permitted for `BEGIN ... END` blocks and for the `LOOP`, `REPEAT`, and `WHILE` statements. Label use for those statements follows these rules:

- `begin_label` must be followed by a colon.
- `begin_label` can be given without `end_label`. If `end_label` is present, it must be the same as `begin_label`.
- `end_label` cannot be given without `begin_label`.
- Labels at the same nesting level must be distinct.
- Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an `ITERATE` or `LEAVE` statement. The following example uses those statements to continue iterating or terminate the loop:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see [Section 13.6.7.2, “DECLARE ... HANDLER Statement”](#).

13.6.3 DECLARE Statements

The `DECLARE` statement is used to define various items local to a program:

- Local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).
- Conditions and handlers. See [Section 13.6.7, “Condition Handling”](#).
- Cursors. See [Section 13.6.6, “Cursors”](#).

`DECLARE` is permitted only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use `DECLARE` to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the `DECLARE` statement, as described in [Section 13.6.4.1, “Local Variable DECLARE Statement”](#).
- Variables can be set directly with the `SET` statement. See [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).
- Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See [Section 13.2.9.1, “SELECT ... INTO Statement”](#), and [Section 13.6.6, “Cursors”](#).

For information about the scope of local variables and how MySQL resolves ambiguous names, see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).

13.6.4.1 Local Variable DECLARE Statement

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case-sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in [Section 9.2, “Schema Object Names”](#).

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).

13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See [Section 13.5.1, “PREPARE Statement”](#).

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with

the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname, id INTO newname, xid
  FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  DECLARE done TINYINT DEFAULT 0;
  DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

  OPEN cur1;
  read_loop: LOOP
    FETCH FROM cur1 INTO newname, xid;
    IF done THEN LEAVE read_loop; END IF;
    SELECT newname;
  END LOOP;
  CLOSE cur1;
END;
```

See also [Section 20.8, “Restrictions on Stored Programs”](#).

13.6.5 Flow Control Statements

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs. It also supports `RETURN` within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

MySQL does not support `FOR` loops.

13.6.5.1 CASE Statement

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

The `CASE` statement for stored programs implements a complex conditional construct.

Note
